CHAPTER 1: INTRODUCTION

1.1 OVERVIEW

The Open Porous Media ("OPM") initiative was started in 2009 to encourage open innovation and reproducible research on modeling and simulation of porous media processes. OPM was initially founded as a collaboration between groups at Equinor (formerly Statoil), SINTEF, the University of Stuttgart, the University of Bergen, but over time, several other groups and individuals have joined and contributed. What today forms the OPM suite of software, has mainly been developed by SINTEF, NORCE (formerly IRIS), Equinor, Ceetron Solutions (OPM Resinsight), Poware Software Solutions, Dr. Blatt HPC-Simulation-Software & Services, and OPM-OP. The initial vision was to create long-lasting, efficient, and well-maintained, open-source software for simulating flow and transport in porous media. The scope has later been extended to also provide open data sets, thus making it easier to benchmark, compare, and test different mathematical models, computational methods, and software implementations.

All software in OPM is distributed under the GNU General Public License ("GPL"), *version 3*, with the option of using newer versions of the license. Datasets are distributed under the Open Data Commons Open Database License ("ODbL"), *version 1.0*, with individual content under the Database Contents License ("DbCL"), *version 1.0*

The project's numerical simulator, OPM Flow, is a fully-implicit, black-oil simulator capable of running industry-standard simulation models[1]. The simulator's input file is compatible with the commercial simulator, although OPM Flow has additional keywords for supporting additional functionality not found in the commercial simulator. The simulator's output files, except for the print and debug files, are compatible with the commercial simulator, and are readable by commercial post-processing software as well as by OPM ResInsight. OPM ResInsight is the Open Porous Media's post-processing software.

The simulator is implemented using automatic differentiation to enable rapid development of new fluid models. In most simulators the coefficients of the linearized systems of equations (Jacobian matrix) required by the non-linear Newton Solver, have traditionally been computed by evaluating the closed-form expressions obtained by differentiating the discretized flow equations analytically. Differentiating these flow equations manually and programming the resulting formulas is time-consuming and error-prone. Thus, even simple extensions in functional dependencies can be difficult to accommodate into existing simulators. Automatic differentiation eliminates these drawbacks.

OPM Flow Runs under Linux and Windows Subsystem for Linux, and the program is in active development with new features added in each bi-annual release. Currently the program has the following functionality:

Model Formulation

- Black-oil with dissolved gas and vaporized oil.
- Rock-dependent capillary and relative-permeability curves.
- End-point scaling and hysteresis.
- Oil vaporization controls (VAPPARS).
- Rock compaction.

Enhance Oil Recovery Models

Enhanced Oil Recovery ("EOR") is a term applied to methods used for recovering oil from a petroleum reservoir beyond that recoverable by primary and secondary methods. Primary recovery normally refers to production using the energy inherent in the reservoir from gas under pressure or a natural water drive. Secondary recovery usually refers to injection of water or water flooding. Thus, Enhanced Oil Recovery is often synonymous with tertiary recovery. Improved Oil Recovery ("IOR") and Advanced Oil Recovery ("AOR") have similar meaning, except they also apply to primary and secondary methods, and sometimes

[1] *Rasmussen, A.F., Sandve, T.H., Bao, K., Lauser, A., Hove, J., Skaflestad, B., Klöfkorn, R., Blatt, M., Rustad, A.B., Sævareid, O. et al. [2019]. The Open Porous Media Flow Reservoir Simulator. arXiv preprint arXiv:1910.06059.*

EOR methods can be used earlier in the sequence. Originally water flooding was considered as Enhanced Oil Recovery, but now EOR is generally considered to follow water flooding.

There are four major EOR groups of methods:

- thermal recovery,
- gas miscible recovery,
- chemical flooding, and
- microbial flooding.

These main groups are further subdivided into individual processes as illustrated in Figure 1.1. For example the thermal recovery methods consist of steam flooding and cyclic steam stimulation, as well as in-situ combustion. Figure 1.1 also includes hot water as a process for thermal EOR, but this process is rarely used in the industry as a drive mechanism, as steam contains significantly more heat than hot water and therefore steam is more effective in heating up the in situ oil. **Note that microbial EOR methods, are not shown in Figure 1.1, due to there limited use in the industry.**

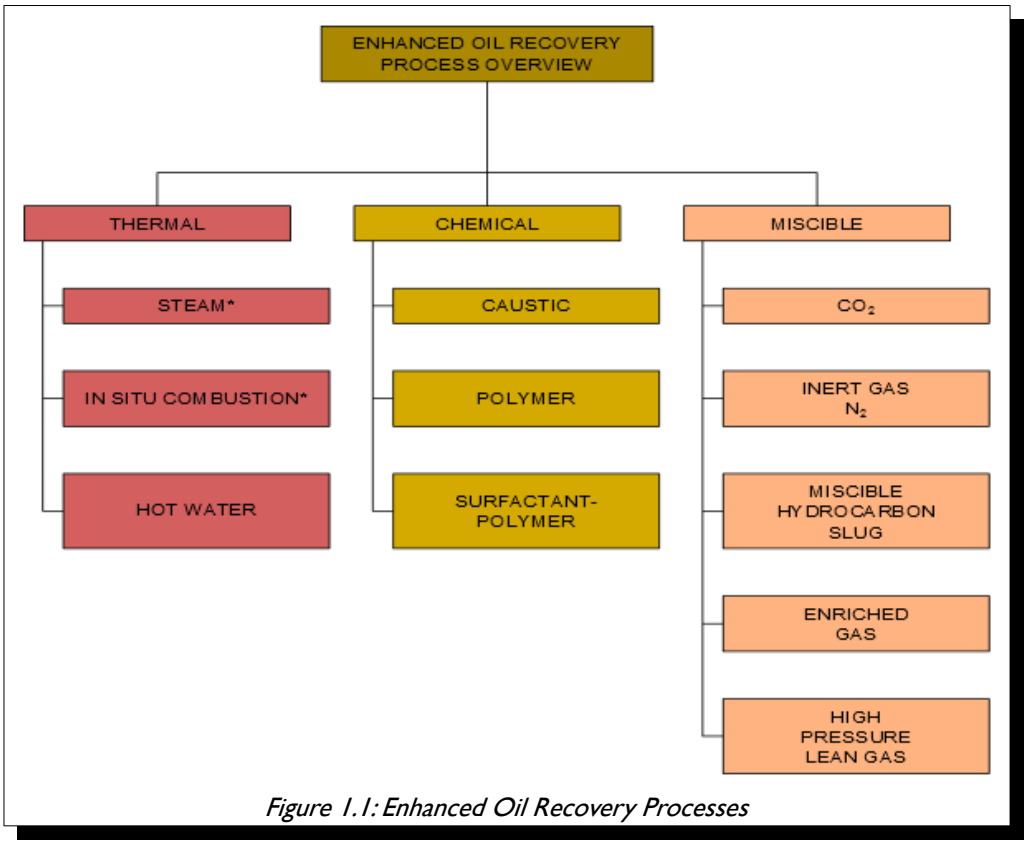

Figure 1.1: Enhanced Oil Recovery Processes

Chemical flooding methods include polymer flooding (including polymer gels), micellar-polymer flooding, and alkaline flooding. Quite often these type of floods are combined to form a more efficient displacement process, for example in an Alkaline Surfactant Polymer ("ASP") process.

Conventional gas flooding is an immiscible process, that is the oil and gas phases remain separate during the displacement drive. For the EOR gas drive process, the displacement is miscible, here the gas "mixes" with the oil to form a single phase fluid in the reservoir. Gas miscible processes are subdivided into carbon dioxide flooding, cyclic carbon dioxide stimulation, nitrogen flooding and nitrogen-CO2 flooding.

OPM Flow has several EOR models based on extending the black-oil model with a fourth component in the simulator.

- CO_2 Standard EOR Model: OPM Flow's CO_2 Standard EOR model is based on on the simulators Solvent model in which uses an extra component by extending the black-oil oil formulation with a fourth component in the simulator by adding a CO2 component to the gas phase. This is the standard formulation used by most black-oil simulators.

- CO_2 Dynamic EOR Model: Although the CO2 Standard EOR model is commonly used, the formulation cannot account for the mass transfer of the various components and phases. The extended black-oil formulations often poorly represent the PVT properties of the oil-CO2 mixtures, resulting in poor agreement with the compositional formulation. OPM Flow's CO2 Dynamic EOR Model black-oil formulation attempts to overcome this limitation by making the black-oil properties dependent on the fraction of CO2 in the cell[2]. This approach models the oil-CO2 mixture more accurately, and thus give results closer to the compositional simulator. Note the model is not restricted to CO2 utilization, as long as the appropriate oil-injection-gas dependent properties are entered in the model.

- Foam Model: An experimental foam module has been added to OPM Flow 2019-10 release. With this it is possible to simulate certain types of surfactant injection. Such injection stimulates formation of foam to change mobility ratios, and give better reservoir sweep. The implemented foam model treats surfactant transported in the gas or water phase, and reduces the mobility of that phase depending on the surfactant concentration. In addition to mobility reduction, foam adsorption to the reservoir rock is also included in the model.

- Polymer Model (Standard): OPM Flow's polymer model is based on a black-oil polymer formulation, which is developed by extending the black-oil model with a polymer component. The effects of the polymer mixing are simulated based on the Todd-Longstaff[3] mixing model, and adsorption, dead pore space, and permeability reduction effects are also considered. A logarithmic shear thinning/thickening model has also been incorporated since the 2015-10 Release (see *Flow-polymer*). Note that the Polymer model has now been incorporated into the main OPM Flow simulator and is no longer a separate simulator.

- Polymer Model (Molecular Weight Transport): In addition to the standard polymer model, the simulator also has the Polymer Molecular Weight Transport option, that uses the polymer molecular weight in calculating the polymer viscosity. Here, the *Mark-Howink equation*, also known as the Mark-Howink-Staudinger equation[4], [5], and [6] is used to calculate the intrinsic viscosity as a function of the molecular weight of the polymer.

- Solvent Model: Similar to the polymer model, OPM Flow's solvent model again uses an extra component by extending the black-oil oil formulation with a fourth component in the simulator by adding a solvent component to the gas phase (see *Flow-solvent*). Note that Solvent model has now been incorporated into the main OPM Flow simulator and is no longer a separate simulator.

CO2 Storage:

- Brine-CO2 PVT module that generates brine and CO2 PVT properties directly eliminating user input for PVT.

- Thermal properties generated by OPM Flow include the CO_2 enthalpy represented as a table internally in the simulator. The liquid enthalpy depends on the dissolved CO2 and salinity as well as pressure and temperature. The water enthalpy is automatically calculated and modified to account for salinity and for CO2 following.

- Diffusion for fine grid modeling is implemented via diffusion coefficients that depend on temperature, pressure, and salinity. The diffusion coefficient is computed internally for pure water and modified to account for salinity. The effect of the porous media on the diffusion is modeled using an industry standard relationship. In addition, the coefficient can also be given as an input parameter using a keyword.

- CO_2 convective dissolution of carbon dioxide (CO2) into in situ brine within a grid cell is implemented together with a convective dissolution parameter for controlling the rate of dissolution.

- Microbially Induced Calcite Precipitation ("MICP") model for the modeling biochemical processes in creating barriers by calcium carbonate cementation, the technology has the potential to be used for sealing leakage zones in geological formations[7] and [8].

Other OPM Flow Specific Enhancements:

- The Salt Precipitation and Water Evaporation Model: The model accounts for water evaporation of the in situ brine and the resulting increasing dissolved salt concentration. Once the salt solubility limit is exceeded, salt precipitation occurs, that results in a decrease in porosity and permeability, and consequently a decrease in gas production. This feature is primary used in modeling gas fields under depletion.

- Thermal Model Enhancements: The energy black-oil implementation in OPM Flow is a mixture of the commercial simulators black-oil temperature and compositional thermal options. These commercial simulator options are two separate modeling facilities in the commercial simulator. OPM Flow's thermal implementation is based on solving the energy equation fully coupled with the black-oil equations, so the results are not directly equivalent to the commercial simulator's black-oil temperature or compositional thermal formulations. In addition, OPM Flow can take into account the Joule–Thomson effect for oil, gas and water. This behavior is especially important in gas wells, when a real gas expands, resulting in the temperature of the gas dropping.

Description of Geology:

- Rectilinear and fully-unstructured grid.

- Corner-point grids from the commercial simulator input, including fault and region multipliers, minimum pore volume, pinch outs, etc.

- Spider grids that are similar to radial grids for modeling near well bore effects that enable visualization in OPM ResInsight.

- Analytical and numerical aquifers.

Well and Group Controls:

- Bottom-hole pressure and surface/reservoir rate.

- Group controls, including voidage replacement, network model, gas lift optimization, guide rate control for producers and injection groups and well, etc.
- Shut/stop/open individual completions.
- History-matching wells.
- Multi-segment wells together with various inflow control devices ("ICDs")
- Well lists.
- Action conditions and command processing via the ACTIONX and UDQ keywords employed in the commercial simulator.
- Python interface to control and process simulator data.

Input and Output:

- General reader/parser for Eclipse input decks.
- XML-based or simple text-format input of additional parameters.
- Flexible output of summary and restart files in he commercial simulator's format.
- Logging to terminal and print file.
- Front-end graphical interface for running the simulator with various tools, including: case compression and uncompression, keyword generation etc.

Simulation Technology:

- Fully-implicit in time.
- Automatic differentiation
- Two-point flux approximation in space with upstream-mobility weighting.
- Flexible assembly through the use of automatic differentiation.
- Bi-conjugate Gradient method (BiCG-stab) and a restarted Generalized Minimal Residual ("GMRes") iterative linear solvers with ILU0 and Constraint Pressure Residual ("CPR") preconditioners.
- Adaptive step-size controls.
- Parallel processing.

The following section briefly the describe the simulator's formulation, equation, and the various numerical procedures available to solve the equations.

Note

The material in the following sections is taken from Rasmussen et al.[9], and the reader is encouraged to read the full paper to obtain a fuller understanding of the simulator's formulation and the resulting equations.

1.2 BLACK-OIL MODEL EQUATIONS

The black-oil equations constitute the most widely used flow model in the simulation of hydrocarbon reservoirs. The model is based on the premise that we have three different fluid phases (aqueous, oleic, and gaseous), and three (pseudo) components: water, oil, and gas. Oil and gas are not single hydrocarbon species, but represent all hydrocarbon species that exist in liquid and vapor form at surface conditions. Mixing is allowed, in the sense that both oil and gas can be found in the oleic phase, in the gaseous phase, or in both. The amount of dissolved gas in the oleic phase and vaporized oil in the gaseous phase must be kept track of on a grid cell basis. In the following discussions the subscripts: w represents the water, o the oil, and g the gas quantities related to each of the phases or components.

The black-oil equations can be deduced from conservation of mass for each component with suitable closure relationships such as Darcy's law and initial and boundary conditions. The equations are discretized in space with an upstream finite-volume scheme using a two-point flux approximation, and in time using an implicit (backward) Euler scheme. The resulting equations are solved simultaneously in a fully implicit formulation by a Newton-type linearization with a properly preconditioned, iterative linear solver (see Rasmussen et al.[10]).

The conservation laws form a system of partial differential equations, one for each pseudo component α:

$$\frac{\partial}{\partial t}\left(\phi_{ref} A_\alpha\right) + \nabla \cdot \mathbf{u}_\alpha + q_\alpha = 0 \tag{1.1}$$

where the accumulation terms and fluxes are given by:

$$A_w = m_\phi b_w s_w \qquad \mathbf{u}_w = b_w \mathbf{v}_w \tag{1.2}$$

$$A_o = m_\phi \left(b_o s_o + r_{og} b_g s_g\right) \qquad \mathbf{u}_o = b_o \mathbf{v}_o + r_{og} b_g \mathbf{v}_g \tag{1.3}$$

$$A_g = m_\phi \left(b_g s_g + r_{go} b_o s_o\right) \qquad \mathbf{u}_g = b_g \mathbf{v}_g + r_{go} b_o \mathbf{v}_o \tag{1.4}$$

and the phase fluxes are given by Darcy's law:

$$\mathbf{v}_\alpha = -\lambda_\alpha \mathbf{K}\left(\nabla p_\alpha - \rho_\alpha \mathbf{g}\right) \tag{1.5}$$

In addition, the following closure relations should hold:

$$s_w + s_o + s_g = 1 \tag{1.6}$$

$$p_{c,ow} = p_o - p_w \tag{1.7}$$

$$p_{c,og} = p_o - p_g \tag{1.8}$$

[10] *Rasmussen, A.F., Sandve, T.H., Bao, K., Lauser, A., Hove, J., Skaflestad, B., Klöfkorn, R., Blatt, M., Rustad, A.B., Sævareid, O. et al. [2019]. The Open Porous Media Flow Reservoir Simulator. https://doi.org/10.1016/j.camwa.2020.05.014.*

where:

ϕ	=	porosity, can be a function of (oil) pressure: $\phi = m_\phi(p_o)\,\phi_{ref}$.
m_ϕ	=	pore volume multiplier as function of pressure.
ϕ_{ref}	=	reference porosity, a constant in time but varying in space.
p_α	=	pressure for phase α.
b_α	=	shrinkage/expansion factor for phase α defined as the ratio of the surface volume at standard conditions to the reservoir volume for a given amount of fluid: $b_\alpha = V_{surface;\alpha} \,/\, V_{reservoir;\alpha}$. For the oil phase, b_o is called the shrinkage factor, whereas for gas b_g is called the expansion factor. The reciprocal quantity is called the formation volume factor, and is usually denoted with a capital B: $B_\alpha = 1 \,/\, b_\alpha$. The variable is usually a function of phase pressure and composition: $b_\alpha = b_\alpha(p_\alpha, r_{go}, r_{og})$.
r_{go}	=	gas-oil ratio ("GOR"), ratio of dissolved gas to oil in the oleic phase, commonly called r_s or R_s in other literature.
r_{og}	=	oil-gas ratio or condensate-gas ratio ("CGR"), ratio of vaporized oil to gas in the gaseous phase, commonly called r_v or R_v in other literature.
s_α	=	saturation of phase α, the pore volume fraction occupied by the phase. The saturations of all phases sum to one.
$p_{c,\alpha\beta}$	=	capillary pressure between phases α and β. Typically a function of saturation: $p_{c,\alpha\beta} = p_{c,\alpha\beta}(S_\alpha)$.
$\mathbf{K}$	=	permeability of the porous medium.
$k_{r;\alpha}$	=	relative permeability for phase α modeling the reduction in effective permeability for a fluid phase in the presence of other phases. Typically a function of saturation.
μ_α	=	viscosity of phase α, typically a function of phase pressure and composition.
λ_α	=	mobility of phase α, given by $\lambda_\alpha = k_{r,\alpha} \,/\, \mu_\alpha$.
$\mathbf{v}_\alpha$	=	velocity of phase α.
$\mathbf{u}_\alpha$	=	velocity of component α.
$\rho_{S,\alpha}$	=	surface density of phase α at one atmosphere, a given constant.
ρ_α	=	density of phase α in the reservoir. For water, $\rho_w = b_w \rho_{S,w}$. For the oleic phase the relationship is more complex since it must include dissolved gas: $\rho_o = b_o(\rho_{S,o} + r_{go}\rho_{S,g})$, and similar for the gaseous phase we have: $\rho_g = b_g(\rho_{S,g} + r_{og}\rho_{S,o})$.
$\mathbf{g}$	=	gravitational acceleration vector.
q_α	=	well out flux density of pseudo component α, (negative for well in-flow). The form of this term depends on the well model used, either the standard well model or the multi-segment model.

Equations (1.1) to (1.8) are then transformed to the discrete form using a forward finite difference scheme. In the following, let subscript i denote a discrete quantity defined in cell i and subscript ij denote a discrete quantity defined at the connection between two cells i and j. Two cells share a connection if they are adjacent geometrically in the computational grid or share an explicit Non-Neighbor Connection ("NNC")[11]. For example $v_{o,ij}$ is the oil flux from cell i to cell j. For oriented quantities such as fluxes, the orientation is taken to be from cell i to cell j, and the quantity is skew-symmetric ($v_{o,ij} = -v_{o,ij}$), whereas non-oriented quantities such as the transmissibility T_{ij} are symmetric ($T_{ij} = T_{ji}$). Quantities with superscript 0 are taken at the start of the discrete time step, other quantities are at the end of the time step. Superscripts or subscripts applied to an expression in parenthesis apply to each element in the expression.

[11] *Connections between cells due to geometric adjacency are automatically calculated by the simulator, including across faults in the grid. In addition, the user can specify extra connections between arbitrary cells using the NNC keyword in the GRID section.*

The discretized equations and residuals are, for each pseudo-component α and cell i :

$$R_{\alpha,i} = \frac{\phi_{ref,i} V_i}{\Delta t}\left(A_{\alpha,i} - A^0_{\alpha,i}\right) + \sum_{j \in C(i)} u_{\alpha,ij} + q_{\alpha,i} = 0 \tag{1.9}$$

where the accumulation terms are the same as equations (1.2) to (1.4) and fluxes u_α are of similar form to the velocities, $\mathbf{u}_\alpha$ in the aforementioned equations; thus we have

$$A_{w\,i} = \left(m_\phi b_w s_w\right)_i \qquad u_{w\,i} = \left(b_w v_w\right)_i \tag{1.10}$$

$$A_{o\,i} = \left(m_\phi\left(b_o s_o + r_{og} b_g s_g\right)\right)_i \qquad u_{o\,i} = \left(b_o v_o + r_{og} b_g v_g\right)_i \tag{1.11}$$

$$A_{g\,i} = \left(m_\phi\left(b_g s_g + r_{go} b_o s_o\right)\right)_i \qquad u_{g\,i} = \left(b_g v_g + r_{go} b_o v_o\right)_i \tag{1.12}$$

In addition, equations (1.6) to (1.8) also hold for each cell i, that is:

$$\left(s_w + s_o + s_g\right)_i = 1 \tag{1.13}$$

$$\left(p_{c,ow}\right)_i = \left(p_o - p_w\right)_i \tag{1.14}$$

$$\left(p_{c,og}\right)_i = \left(p_o - p_g\right)_i \tag{1.15}$$

Finally, the fluxes are given for each connection ij by the following relationships:

$$\left(b_\alpha v_\alpha\right)_{ij} = \left(b_\alpha \lambda_\alpha m_T\right)_{U_{(i,\alpha,ij)}} T_{ij} \Delta\Phi_{\alpha,ij} \tag{1.16}$$

$$\left(r_{\beta\alpha} b_\alpha v_\alpha\right)_{ij} = \left(r_{\beta\alpha} b_\alpha \lambda_\alpha m_T\right)_{U_{(i,\alpha,ij)}} T_{ij} \Delta\Phi_{\alpha,ij} \tag{1.17}$$

$$\Delta\Phi_{\alpha,ij} = p_{\alpha,i} - p_{\alpha,j} - g\rho_{\alpha,ij}\left(z_i - z_j\right) \tag{1.18}$$

$$\rho_{\alpha,ij} = \frac{\left(\rho_{\alpha,i} + \rho_{\alpha,j}\right)}{2} \tag{1.19}$$

$$U(\alpha,ij) = \begin{cases} i, & \Delta\Phi_{\alpha,ij} \geq 0 \\ j, & \Delta\Phi_{\alpha,ij} \geq 0 \end{cases} \tag{1.20}$$

where:

V	=	cell volume.
Δt	=	time step length for the current Euler step.
v_α	=	volume flux of phase α (oriented quantity).
u_α	=	surface volume flux of pseudo component α (oriented quantity).
T_{ij}	=	transmissibility factor for a connection, derived from permeability.
m_T	=	transmissibility multiplier as function of pressure.
$C(i)$	=	connections from cell i, i. e. the set of cells connected to it.
$U(\alpha,ij)$	=	upwind cell for phase α for the connection between cells i and j.
$\Delta\Phi_{(\alpha,ij)}$	=	potential difference for phase α for the connection between cells i and j (oriented quantity).
g	=	gravitational acceleration in the z-direction.
z_i	=	depth of center of cell i.

For a grid containing a total of n active cells, the material balance relationship expressed by equation (1.9) results in a system of 3n equations for the three phase formulation (oil, water, gas). Similarly, for the two phase model, oil-water or gas-water, there are 2n equations to be solved. In addition, there are also the sink and source terms associated with the wells. The solution variables for the system of equations is dependent on the state of a cell, basically, for:

1) Non-miscible: Here pressure of one of the phases (which we take to be oil pressure p_o), s_w, and s_g as our primary variables. The pressure p_o will then behave mostly in an elliptic fashion, whereas the saturations s_w and s_g are more hyperbolic.

2) Miscible flow: Since the gaseous phase may disappear if all the gas dissolves into the oleic phase, and similarly the oleic phase may disappear if all the oil vaporizes into the gaseous phase, one cannot always use s_g for our third variable. Instead we use the third variable to track the composition of the phase that has not disappeared. We therefore use either s_g, r_{go}, or r_{og} as our third primary variable, depending on the fluid state, and we call that variable x:

$$x = \begin{cases} s_g, & \text{all three phases present,} \\ r_{go}, & \text{no gaseous phase,} \\ r_{og}, & \text{no oleic phase.} \end{cases} \tag{1.21}$$

This choice is made separately for each cell i depending on its state.

The next two sections describe the formulation of the two well models implemented in OPM flow: the Standard Well Model and the Multi-Segment Well Model.

1.3 STANDARD WELL MODEL

For the standard well model, in a three phase black-oil system, there are four primary variables, three fluid variables: Q_t, F_w, and F_g, which describe the fluid composition within the wellbore[12], as depicted in the following equation:

$$Q_t = \sum_{\alpha \in \{o,g,w\}} g_\alpha Q_\alpha, \qquad F_w = \frac{g_w Q_w}{Q_t}, \qquad F_g = \frac{g_g Q_g}{Q_t} \tag{1.22}$$

where:

Q_t = the weighted total flow rate,
F_w = the weighted fraction of water, and
F_g = the weighted fraction of gas.

Here, Q_α is the flow rate of component α under surface conditions and g_α is a weighting factor. For gas, this factor is typically chosen to be a small value, for example, 0.01 to avoid gas fractions close to unity[12].

The fourth variable is the bottom-hole pressure (p_{bhp}), that is the pressure in the wellbore at the datum depth.

Volumetric inflow rates at reservoir conditions are calculated as:

$$q^r_{\alpha,j} = T_{w,j}\, M_{\alpha,j} \left[p_j - (p_{bhp,w} + h_{w,j}) \right] \tag{1.23}$$

where:

$q^r_{\alpha,j}$ = is the flow rate of phase α through connection j. The rate is negative for flow from the wellbore to reservoir, and positive for flow into the opposite direction.

[12] *J. Holmes, Enhancements to the strongly coupled, fully implicit well model: wellbore crossflow modeling and collective well control, in: SPE Reservoir Simulation Symposium, Society of Petroleum Engineers, 1983.*

$T_{w,j}$	=	connection transmissibility factor.
$M_{\alpha,j}$	=	the mobility for phase α at the connection j. For injection wells, the total mobility of the injecting phase is used, as per Holmes12.
p_j	=	pressure of the grid block that contains the connection j.
$p_{bhp,w}$	=	the bottom-hole pressure of well w.
$h_{w,j}$	=	pressure difference within the wellbore between connection j and the well's bottom-hole datum depth. The pressure differences $h_{w,j}$ between connection j and the datum point are computed explicitly based on the fluid composition in the wellbore at the start of the time step.

To keep the system closed, we introduce conservation equations for each component using:

$$R_{\alpha,w} = \frac{A_{\alpha,w} - A^0_{\alpha,w}}{\Delta t} + Q_\alpha - \sum_{j \in C(w)} q_{\alpha,j} = 0 \tag{1.24}$$

Equation (1.24) is solved in a fully implicit and coupled way with the black-oil equations, as per equation (1.9)). Here, $C(w)$ is the set of connections of the well w, $q_{\alpha,j}$ is the flow rate of phase α through connection j under surface condition, which can be calculated from $q^r{}_{\alpha,j}$ defined in equation (1.23); the relationship is similar to the one between component and mass fluxes, as per equations (1.2) through (1.4). The storage term $A_{\alpha,w}$ describes the amount of component α in the wellbore (a small volume, that is 0.1 ft3 as per Holmes12), and it is introduced for better stability of the well solution.

In addition, we need equations that model how the wells are controlled. For wells controlled by a prescribed bottom-hole pressure (bhp) target, we have:

$$R_{c,w} = p_{bhp,w} - p^{target}_{bhp,w} = 0 \tag{1.25}$$

whereas for a rate-controlled well we have:

$$R_{c,w} = Q_\alpha - Q^{target}_\alpha = 0 \tag{1.26}$$

Where Q^{target}_α is the desired surface-volume rate of the controlled component α, typically oil or gas rate for a production well. The Standard Well model handles cross-flow, that is flow exiting from one well connection and entering another connection; however, this model assumes that the fluid composition is uniform throughout the wellbore (given by Fg and Fw), and thus the same composition will be injected through all injecting connections. When this is not a reasonable assumption, then the Multi-Segment model should be used instead, which is the topic of the next section.

1.4 MULTI-SEGMENT WELL MODEL

Multi-segment wells were introduced to handle more complex well configurations, including for example horizontal, multi-lateral and fish bone well types, as well Inflow Control Devices ("ICD")[13]. This model divides the wellbore into a number of arbitrary segments. Each segment has a segment node and a flow path to the neighboring segment in the direction towards the well head, that defines as the outlet segment (Figure 1.2). Most segments also have inlet segment neighbors in the direction away from the well head. For multi-lateral wells, a segment node must be placed at the branch junction. Segments at branch junction points have additional inlet segments and segments at the end of branches do not have inlet segments. The top segment of each well does not have an outlet segment. The pressure at this segment is the bottom-hole pressure of the well, whereas the component rates equal the component rates for the well as a whole. For example, Figure 1.3 on the following page, shows the main wellbore branch together with four offsetting branches.

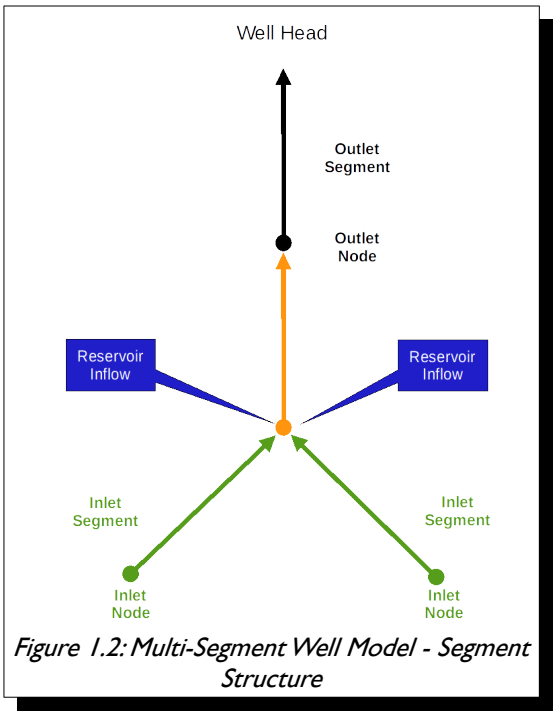

Figure 1.2: Multi-Segment Well Model - Segment Structure

Each segment has the node pressure p as a primary variable in addition to the primary variables Q_t, F_w, and F_g introduced for the standard well model, as per equation (1.22). Similarly, the component equations, (1.24), are extended to include the additional $Q_{\alpha,i}$ terms that represent the flow rate from the inlet segments $I(n)$ of segment n, as well as the inflow from the reservoir through the segment's connections $C(n)$. Thus, the equivalent standard well equation (1.24) for multi-segment wells is:

$$R_{\alpha,n} = \frac{A_{\alpha,n} - A^0_{\alpha,n}}{\Delta t} + \sum_{i \in I(n)} Q_{\alpha,i} - \sum_{j \in C(w)} q_{\alpha,j} + Q_{\alpha,n} = 0 \qquad (1.27)$$

Each segment can thus receive inflow from more than one connection or no connection through the segment node, whereas each connection can only contribute to one segment. In the standard well model, the connection is located at the centroid of the grid block. In the multi-segment well model, the connection and segment node can be located at any place within the grid block. The inflow calculation of the connection in the multi-segment well model is as follows:

$$q^r{}_{\alpha,j} = T_{w,j} M_{\alpha,j} \left(p_j + H_{c,j} - p_n - H_{nc} \right) \qquad (1.28)$$

where:

p_j = the pressure at the cell center of the grid block that contains connection j,

$H_{c,j}$ = the hydrostatic pressure difference between the cell center and the connection,

p_n = the pressure of segment n, and

H_{nc} = the hydrostatic pressure difference between the connection and the segment.

[13] *J. Holmes, T. Barkve, O. Lund, Application of a multisegment well model to simulate ow in advanced wells, in: European Petroleum Conference, Society of Petroleum Engineers, 1998.*

The last equation for each segment describes the pressure relationships between the segment n and its outlet segment m:

$$R_{p,n} = p_n - p_m - H_h - H_f - H_a = 0 \tag{1.29}$$

Here, the H terms represent the hydrostatic, frictional, and acceleration pressure drops between the segments.

The top segment does not have an outlet segment, and hence the pressure equation is replaced by a well control equation, which is the same as for the standard well model, that is either equation (1.25) or (1.26).

As with the standard well model, the well equations are solved with the reservoir mass conservation equations in a coupled, fully implicit way. The well equations are added to the global system using a Schur[14] complement approach:

$$\left(A - \sum_w C_w D_w^{-1} B_w\right) x_r = R_r - \sum_w C_w D_w^{-1} R_w \tag{1.30}$$

$$x_w = D_w^{-1}\left(R_w - B_w x_r\right)$$

Figure 1.3 depicts a multi-segment well with the main wellbore branch as the vertical segment, together with four offsetting horizontal branches.

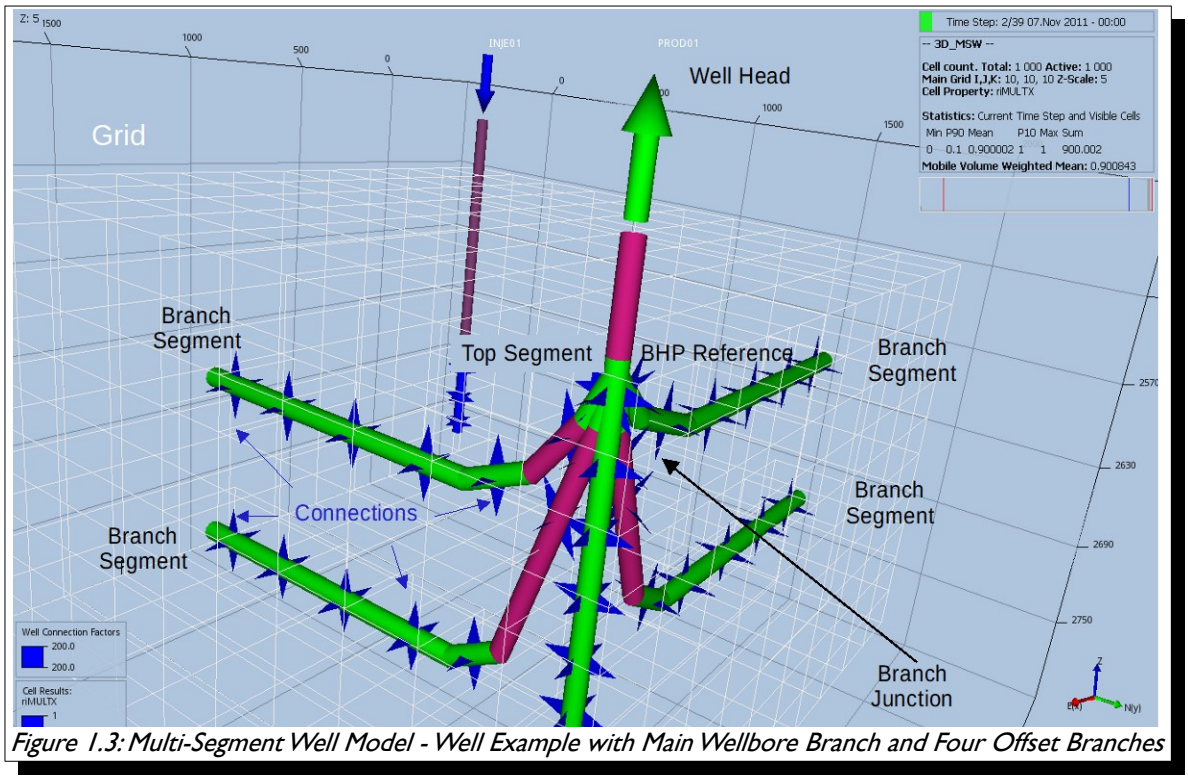

Figure 1.3: Multi-Segment Well Model - Well Example with Main Wellbore Branch and Four Offset Branches

1.5 SALT PRECIPITATION MODEL

OPM Flow's salt precipitation and water evaporation model is an extension of the black-oil model with a water in gas component, plus addition of a solid salt phase component to the salt transport equation. The effects of porosity and permeability reduction effects are also considered. The oil, gas and water and salt conservation equations including these extensions are given by equations (1.31) to (1.34).

Oil:

$$\frac{\partial}{\partial t}\left[\phi\left(b_o s_o + r_{og} b_g s_g\right)\right] + \nabla\cdot\left(b_o v_o + r_{og} b_g v_g\right) + q_o = 0 \tag{1.31}$$

Gas:

$$\frac{\partial}{\partial t}\left[\phi\left(b_g s_g + r_{go} b_o s_o\right)\right] + \nabla\cdot\left(b_g v_g + r_{go} b_o v_o\right) + q_g = 0 \tag{1.32}$$

Water:

$$\frac{\partial}{\partial t}\left[\phi\left(b_w s_w + r_{wg} b_g s_g\right)\right] + \nabla\cdot\left(b_w v_w + r_{wg} b_g v_g\right) + q_w = 0 \tag{1.33}$$

Salt:

$$\frac{\partial}{\partial t}\left[\phi b_w s_w c_w^{salt} + m_\phi \phi_0 s_s \rho^{salt}\right] + \nabla\cdot\left(c_w^{salt} b_w v_w\right) + c_w^{salt} q_w = 0 \tag{1.34}$$

where:

ϕ	=	porosity.
m_ϕ	=	pore volume multiplier as function of pressure.
ϕ_0	=	reference porosity, a constant in time but varying in space.
p_α	=	pressure for phase α.
b_α	=	shrinkage/expansion factor for phase α defined as the ratio of the surface volume at standard conditions to the reservoir volume for a given amount of fluid: $b_\alpha = V_{surface;\alpha} \,/\, V_{reservoir;\alpha}$. For the oil phase, b_o is called the shrinkage factor, whereas for gas b_g is called the expansion factor. The reciprocal quantity is called the formation volume factor, and is usually denoted with a capital B: $B_\alpha = 1 / b_\alpha$. The variable is usually a function of phase pressure and composition.
r_{go}	=	gas-oil ratio ("GOR"), ratio of dissolved gas to oil in the oleic phase, commonly called r_s or R_s in other literature.
r_{og}	=	oil-gas ratio or condensate-gas ratio ("CGR"), ratio of vaporized oil to gas in the gaseous phase, commonly called r_v or R_v in other literature.
r_{wg}	=	evaporated water in gas ratio.
s_α	=	saturation of phase α, the pore volume fraction occupied by the phase.
s_s	=	saturation of precipitated salt (volume fraction).
ρ_α	=	surface density of phase α at one atmosphere, a given constant.
ρ^{salt}	=	density of the solid salt.

q_α = well out flow of component α, (negative for well in-flow).
The form of this term depends on the well model used, either the standard well model or the multi-segment model.

c_w^{salt} = salt concentration in water (mass per unit volume).

The extension has two extra primary variable switching mechanisms. One between s_w and r_{wg}, when water disappears and reappears, and one between c_w^{salt} and s_s when the salt concentration reaches the (user defined) solubility limit and salt precipitates or when solid salt dissolves. Furthermore, in the new formulation porosity becomes:

$$\phi = \left(1 - s_s\right) m_\phi \phi_0 \tag{1.35}$$

The resulting (reduced) permeability, k, is based on a user specified permeability-porosity relation $k = k(\phi)$.

Both for dry and humid gas and wet and humid gas the PVT data can be provided using dedicated PVT tables. For the capillary pressure data it is recommended to extend its values towards zero water saturation to permit water saturations below the irreducible water saturation due to water evaporation.

For further details see Machado et al.[15]

1.6 NUMERICAL SOLUTION OF EQUATIONS

Efficiently solving the aforementioned equations is non-trivial, and involves a step iterative process that consists of an outer, Newton-Raphson type method, of a series of iterations, and an inner set of linear iterations, as depicted in Figure 1.4, which shows a simplified schematic of the iterative scheme.

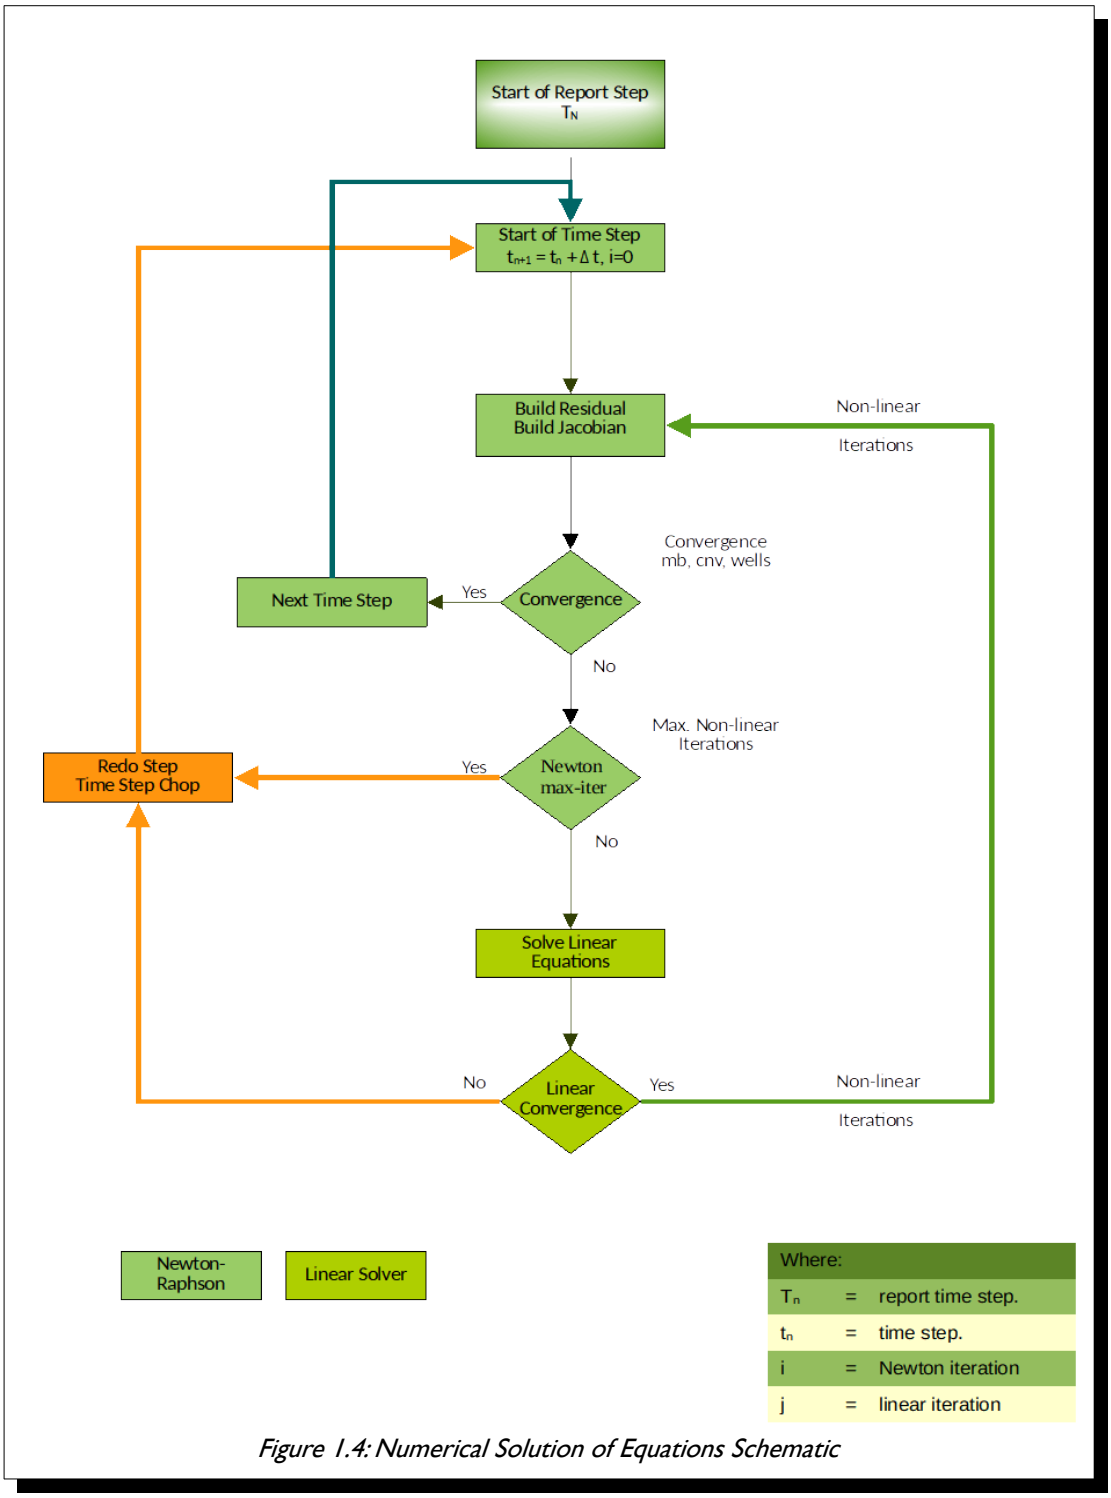

Figure 1.4: Numerical Solution of Equations Schematic

The next two sections attempt to give an overview of the two numerical schemes.

1.6.1 NEWTON-RAPHSON SOLVER (OUTER ITERATION)

The aforementioned reservoir and well equations define a large system of (fully implicit) non-linear equations, which one can write in compact residual form as R(y) = 0, where y is the vector of primary variables, p_o, s_w, x. This system is solved using a Newton-Raphson type method.

Let $y_n=(p_o, s_w, x)$ be the primary variables after n Newton iterations, and given the initial state y_0, the solution of $R(y)=0$ can be found by iteratively solving:

$$J(y_n)(y_{n+1} - y_n) = -R(y_n) \tag{1.36}$$

until $R(y_n)$ satisfies a given tolerance. Creating the Jacobian matrix $J(y_n)$ and solving this linearized problem is the core computational task of the simulator, and its performance depends largely on how this part of the code is programmed.

The coefficients of the linearized systems required by the non-linear Newton solver, $J(y_n)$ in equation (1.36), have traditionally been computed by evaluating closed-form expressions obtained by differentiating the discretized flow equations analytically. Differentiating these flow equations manually and programming the resulting formulas is both time-consuming and error-prone. The problem is particularly pronounced when extending an existing simulator with new functional relationships. If a quantity is set to depend on a different or new (primary) variable, the changes in derivatives will propagate through the chain rule to the Jacobians of all quantities that depend on the modified quantity. Thus, even very simple extensions in functional dependencies may cause large modifications throughout the simulator code.

Automatic Differentiation ("AD") is a way to mitigate this problem[16] and [17], and there are many examples of AD tools used for scientific computing, such as Sacado[18], ADOL-C[19] or ADETL[20]; with the latter used for the AD-GPRS[21] reservoir simulator at Stanford University.

The OPM Flow's implementation of AD introduces a class that mimics the behavior of the built-in floating point types of C++ (double and float) as closely as possible. The AD object contains a value and a fixed number of derivatives and defines all basic arithmetic operators as well as common mathematical functions. Also, to allow easy comparisons with code that uses standard floating-point objects, all functions that work on AD-objects can also be used with objects of built-in floating-point types. For further detailed information on OPM Flow's implementation of AD, again see Rasmussen et al.[22].

When solving the Newton-Raphson equation (1.36), the first iteration at the new time step uses the solution at the end of the previous time step (t_n), as an initial estimate for the new time step (t_{n+1}). Thus, the Newton-Raphson iteration is expected to converge rapidly for sufficiently small time steps. For large time steps and/or large changes in the solution, typically caused by changing well controls, the Newton-Raphson method may converge poorly or not at all. There are several means in which one can increase the probability of convergence, namely:

1) Restrict the change allowed per iteration and prevent the solution from jumping far across the boundary between saturated and undersaturated states in a single iteration. Thus, like the commercial simulator, OPM Flow implements the Appleyard[23] chop technique, which is often sufficient for the method to converge. However, time step chops[24] may still occur in order to obtain convergence for some difficult cases, particularly for models with very fine grids.

2) Secondly, since the third primary variable, x ,may change solution state from one iteration to the next, this may disturb the convergence, and therefore a small threshold is applied (ε) to the variable-switching logic for equation (1.21), in order to prevent oscillation between states.

3) Thirdly, and frequently the main cause of non-convergence and the lack of smoothness of the residuals, is the discontinuity or inconsistent input data, particularly the relative permeability and capillary pressure functions. Thus, using Corey[25] or Lomeland et al.[26] type of curves for these data may well improve convergence performance, see *SGOFLET– Gas-Oil LET Relative Permeability Functions*, *SGWFLET – Gas-Water LET Relative Permeability Functions*, and *SWOFLET – Water-Oil LET Relative Permeability Functions*, for OPM Flow's implementation of the Lomeland type of curves.

4) The final point that influences the convergence of the non-linear solver is the accuracy of the linear solvers, as discussed in the next section.

For more information about run time options and numerical controls, see section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.

[23] *J. Appleyard, I. M. Cheshire, Nested factorization, in: 7th SPE Symposium on Reservoir Simulation, San Francisco, USA, Society of Petroleum Engineers, 1983. doi:10.2118/12264-MS.*

[24] *A time step chop occurs when convergence is not achieved within the allowable number of iterations. For example, if the simulator was attempting to take a 30 day time step and failed, then the time step would be cutback, to say ten days, and the iterations restarted. If this 10 day time step also failed to converge, then a second time step chop would occur reducing the new time step, to say three days. This process is repeated until either convergence is achieved, or the time step is too small to chop and the simulation stops.*

1.6.2 LINEAR SOLVER (INNER ITERATION)

As mentioned previously, efficiently solving the aforementioned equations is non-trivial, and involves a step iterative process that consists of an outer, Newton-Raphson type method, series of iterations, and an inner set of linear iterations, as depicted in the detailed work flow of the iterative process in Figure 1.5.

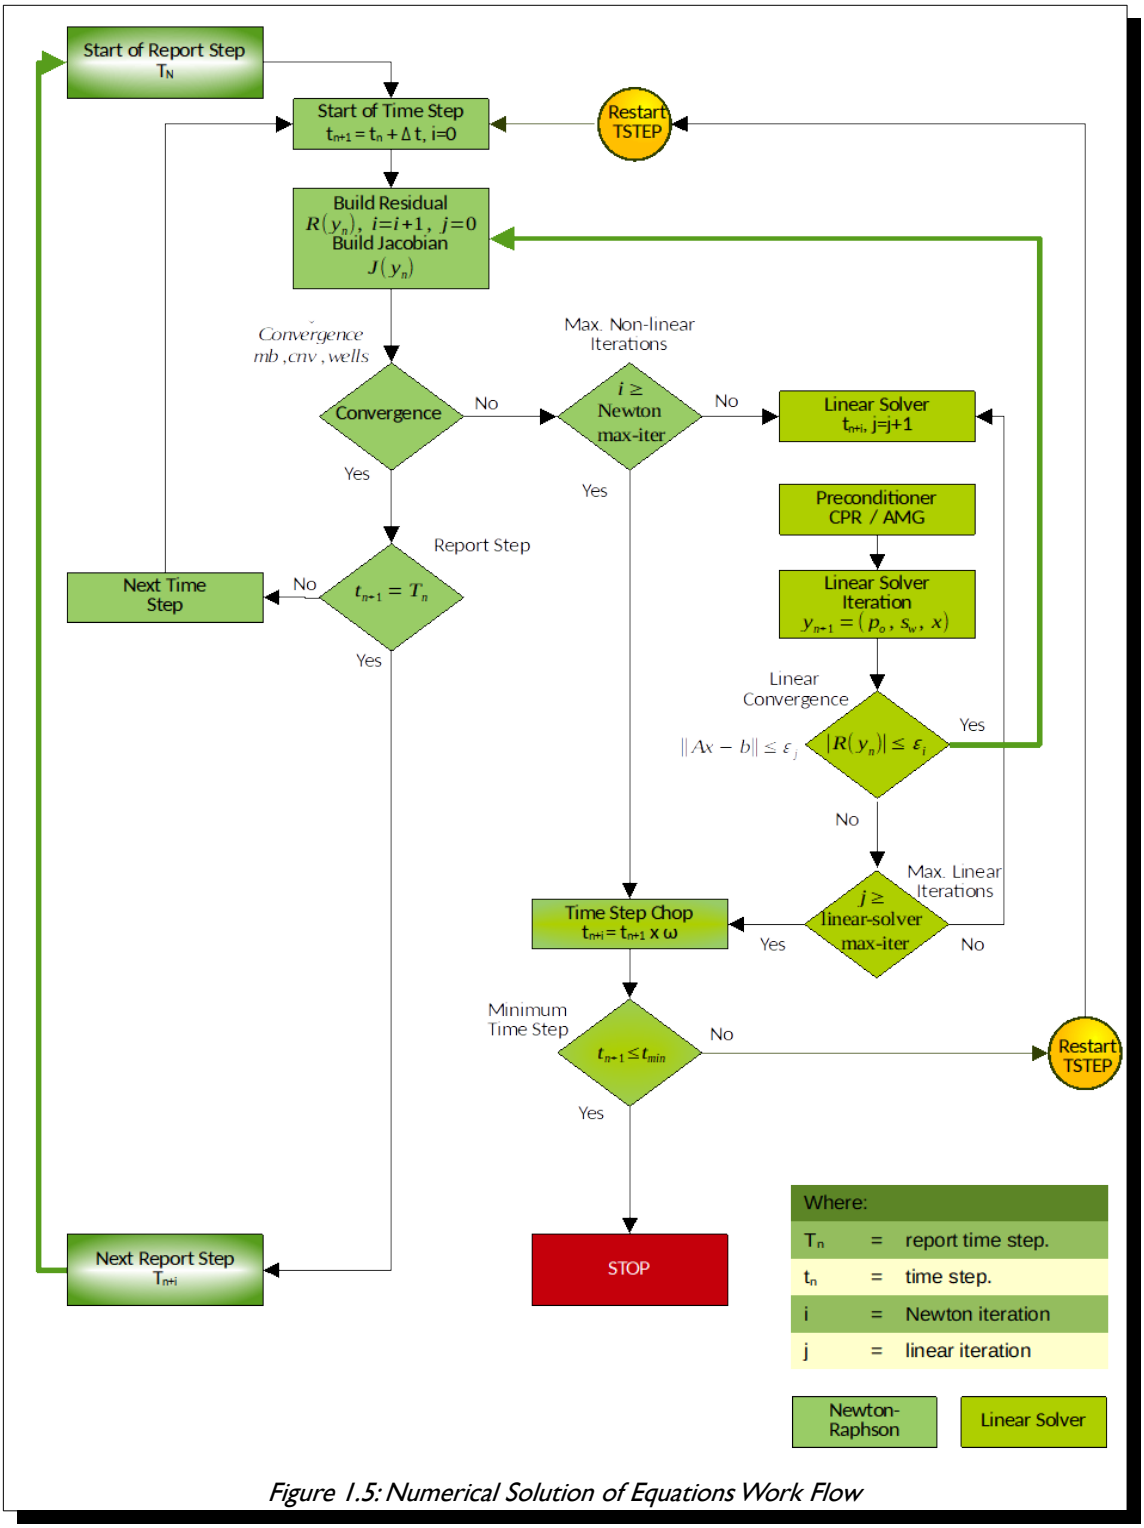

Figure 1.5: Numerical Solution of Equations Work Flow

Depending on the fluid properties and other reservoir specific parameters, the system of equations as described by equation (1.9), that is:

$$R_{\alpha,i} = \frac{\phi_{ref,i} V_i}{\Delta t}\left(A_{\alpha,i} - A^0{}_{\alpha,i}\right) + \sum_{j \epsilon C(i)} u_{\alpha,ij} + q_{\alpha,i} = 0 \quad \textbf{(1.9)}$$

could exhibit elliptic or degenerate parabolic behavior, or could even be hyperbolic for specif setups. Therefore, solving the linearized system stemming from these equations is challenging, since it is likely non-symmetric and ill-conditioned. Thus, instead of solving equation (1.36), that is:

$$J(y_n)\left(y_{n+1} - y_n\right) = -R(y_n) \quad \textbf{((1.36))}$$

directly, the solution is approximated by an iterative linear solver. Two variants are available in OPM Flow:

1) a stabilized Bi-conjugate Gradient method (BiCG-stab), and
2) a restarted Generalized Minimal Residual (GMRes) solver.

By default, BiCG-stab is used. In addition, there are several options available for preconditioning the linear system. The default choice being the incomplete lower triangular-upper triangular factorization with level of fill in 0 (ILU0). More sophisticated choices are based on an algebraic multi-grid (AMG) method for preconditioning, such the Constraint Pressure Residual (CPR) preconditioner (originally introduced by Wallis[27] using the approach of Scheichl et al.[28]). The solvers and preconditioners are implemented in the Dune module dune-istl and described by Blatt et al.[29], [30], and [31]. The interface between OPM Flow and the linear solver packages has been designed in a flexible way so that besides dune-istl other linear algebra packages could be used.

For more information about run time options and numerical controls, see section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface. In addition, section *2.4 Improving Simulator Convergence and Numerical Performance* provides some practical advice on how to address numerical performance issues.

1.7 FORMATION DAMAGE MODELS

1.7.1 INCOMPRESSIBLE EXTERNAL FILTER CAKE MODEL – LINEAR GEOMETRY

This simple model assumes that all of the filtrate is captured on the formation surface to form a filter cake of constant porosity and permeability. Hence, the filter cake will simply grow in thickness as a function of the volume of deposited material, and a simple volume balance assuming linear flow yields,

$$A_f l_c(t)(1-\phi_c) = f_s \int_0^t q(\tau)\, d\tau = f_s Q_c(t) \tag{1.36}$$

Here A_f is the area of flow, l_c is the filter cake thickness, ϕ_c is the filter cake porosity, f_s is the volume concentration of suspended material, q is the injection rate, Q_c is the cumulative injected volume, and t is time. The filter cake thickness is hence,

$$l_c(t) = \frac{f_s Q_c(t)}{A_f(1-\phi_c)}. \tag{1.36}$$

Assuming a constant filter cake permeability k_c, and viscosity μ, Darcy's law for the pressure drop across the filtrate gives the damage pressure drop ΔP_d as,

$$\Delta P_d(t) = \frac{q\mu f_s Q_c(t)}{k_c A_f^2(1-\phi_c)} \tag{1.36}$$

Skin factor,

$$S = \frac{f_s}{1-\phi_c}\frac{k}{k_c}\frac{Q_c(t)}{A_f r_w} = \frac{l_c}{r_w}\frac{k}{k_c} \tag{1.36}$$

Here k is the rock permeability. The linear flow assumption is valid for flow near a fracture surface, and it is also a decent approximation for radial flow assuming that the filter cake is thin compared to the well radius.

1.7.2 INCOMPRESSIBLE EXTERNAL FILTER CAKE MODEL – RADIAL GEOMETRY

Deposition Inside the Wellbore

Simple volume balance on deposited filtrate inside a well in radial geometry yields, for a 2D cross section perpendicular to the well,

$$\pi r_w^2 - \pi r_c^2 = \frac{f_s}{1-\phi_c}\int_0^t q_h(t)\, dt = \frac{f_s}{1-\phi_c} Q_h(t) \tag{1.36}$$

Here q_h and Q_h are rate and cumulative injected volume per length. This may be solved for the filtrate inner radius r_c to compute the cake thickness $r_w - r_c$ as,

$$\Delta r_c(t) = r_w - r_c = r_w - \sqrt{r_w^2 - \frac{f_s Q_h(t)}{\pi(1-\phi_c)}} \tag{1.36}$$

The pressure drop across the filter cake is then given as,

$$\Delta P_c = \frac{q\mu}{2\pi k_c} \ln \frac{r_c}{r_w} \tag{1.36}$$

The skin is simply,

$$S = \frac{k}{k_c} \ln \frac{r_w}{r_c} \tag{1.36}$$

Deposition in the Reservoir

If the filtrate is instead deposited in the near-well reservoir (i.e., outside the well), we will have $r_c > r_w$, and the skin factor will be,

$$S = \frac{k}{k_c} \ln \frac{r_c}{r_w} \tag{1.36}$$

For implementation convenience and consistency with the linear geometry case the filter cake thickness may be expressed in terms of a connection area, $A_f = 2\pi r_w h$, so that with Q being the cumulative injected volume, the filter cake radius follows from,

$$r_c^2 = r_w^2 + \frac{2 r_w f_s Q(t)}{A_f(1-\phi_c)} \tag{1.36}$$

CHAPTER 2: INSTALLING AND RUNNING FLOW

2.1 INSTALLING OPM FLOW

OPM Flow can be installed and used in a variety of ways. Perhaps the simplest way is to use the operating system's package manager to install the OPM modules as binary packages, including OPM Flow and other OPM programs. That way all prerequisite libraries will automatically be installed on the system. This is supported on Ubuntu Linux version 20.04 and Red Hat Enterprise (or CentOS) version 6 or 7.

OPM Flow can also be used via a Docker container. This allows OPM Flow to run on any system that supports Docker, including Microsoft Windows, without installing prerequisite libraries or affecting any other software on your system.

Finally, OPM Flow can be installed by compiling from source on Linux or macOS systems.

2.1.1 UBUNTU LINUX 20.04 (64-BIT VERSION ONLY) AND HIGHER

The easiest way to install the Ubuntu packages is to first add the OPM personal package archive (ppa). In order to do that we need to install the apt-add-repository command.

```
sudo apt-get update
sudo apt-get install software-properties-common
```

Then we add the repository, and run update again:

```
sudo apt-add-repository ppa:opm/ppa
sudo apt-get update
```

At this point, all the OPM modules should be available to install. To see a list of (for example) the opm-simulators packages:

```
apt-cache search opm-simulators
```

Then to install the opm-simulators programs (including OPM Flow) and their dependencies:

```
sudo apt-get install mpi-default-bin
sudo apt-get install libopm-simulators-bin
```

To optionally install the OPM Python bindings use:

```
sudo apt install python3-opm-simulators
```

Notes

1) The mpi install above is required for the mpi libraries which the OPM executables are linked to, even those that are not intended to be run with mpirun. The reason the OPM packages do not depend on that package is that by Debian policy the user should be allowed to choose which MPI implementation to use (above we picked the default set by Ubuntu). Also, note that due to some problems with the OpenMPI packages in Ubuntu 18.04, OPM has rolled out its own custom MPI packages to prevent this bug for this release of the operating system.

2) If an old versions of prerequisite libraries have already been installed (for example from installing a previous release of OPM Flow) it might be necessary to upgrade them via the following commands:

```
sudo apt-get update

sudo apt-get upgrade
```

3) Some users have experienced trouble with OPM Flow simply aborting with no error message. In some cases that can be related to locale issues. Check by running the "locale" command. OPM Flow requires the "C" or an English locale to run correctly. One way to fix this can be to put the following in your ".bash_profile" (note the initial period or full stop in the filename), and open a new terminal (command) window:

```
LANG="en_US.UTF-8"

export LANG

LC_ALL="en_US.UTF-8"

export LC_ALL
```

2.1.2 RED HAT ENTERPRISE OR CENTOS (VERSION 6 OR 7)

First add the OPM package repository:

```
sudo yum-config-manager --add-repo \
http://www.opm-project.org/package/opm.repo
```

The OPM software is split in several packages. To list all available OPM packages one can use:

```
sudo yum search opm-
```

For example you can install the opm-simulators binary package to get access to the OPM Flow reservoir simulator:

```
sudo yum install opm-simulators-bin
```

Development packages are available using the -devel suffix. For example, to install the opm-upscaling development package use:

```
sudo yum install opm-upscaling-devel
```

Notes

1) If you wish to install the MPI parallel version of Flow, you must choose an MPI implementation, either mpich or openmpi, and instead use the following command:

```
sudo yum install opm-simulators-openmpi-bin
```

2) For mpich, just replace openmpi with mpich in the above command. In order to run Flow in parallel using mpirun you must also load the required module first:

```
module load mpi/openmpi-x86_64
```

The above command works for RHEL 7, for RHEL 6 you must drop the "mpi/" part. To use mpich instead, replace openmpi with mpich in the above command.

2.1.3 WINDOWS 7 AND 10 USING VIRTUALBOX

Oracle VM VirtualBox's (formerly Sun VirtualBox, Sun xVM VirtualBox and Innotek VirtualBox) is a free and open source hosted hypervisor for x86 virtualization, developed by Oracle Corporation. The software was originally created by Innotek, who were acquired by Sun Microsystems in 2008, which was in turn acquired by Oracle in 2010. VirtualBox can be installed on Windows, macOS, Linux, Solaris and Open Solaris operating systems. The software supports the creation and management of guest virtual machines running Windows, Linux, BSD, OS/2, Solaris, Haiku, and OSx86, as well as limited virtualization of macOS guests on Apple hardware For some guest operating systems, a "Guest Additions" package of device drivers and system applications is available, which typically improves performance, especially that of graphics[32].

The OPM web site outlines the install process using VirtualBox, Vagrant[33] and a Vagrant file to automatically set up a virtual environment – see *https://opm-project.org/?page_id=294&page=2* for details on this approach.

Alternatively, one can use the more standard approach of installing virtual machines using VirtualBox. The basic outline for this method to use VirtualBox to run a guest Linux distribution and install OPM Flow in the guest Linux virtual machine. Note only the Linux distributions mentioned previously should be used as a guest virtual machine, although any of the Ubuntu "flavors" (Kubuntu, Lubuntu, Ubuntu Mate etc.) will work as well. The steps are:

1) Installing VirtualBox[34]
   - First download the latest VirtualBox software from Oracle's web site at *https://www.virtualbox.org/* for Windows host machines.
   - Install the software via double clicking on the executable and following the on screen instructions.
2) Create a Guest Linux Virtual Machine.
   - Download a suitable Linux distribution in ISO format that supports running OPM Flow, for example Ubuntu 20.04 LTS (64-bit version only) from *https://ubuntu.com/download/desktop* or CentOS Linux (version 6 or 7) from *https://www.centos.org/download/*.
   - Start VirtualBox, which should display a screen similar to Figure 2.1 without all the guest virtual machines.

[32] *After* https://en.wikipedia.org/wiki/VirtualBox.

[33] *See* https://www.vagrantup.com/ *for details*

[34] *See also* https://www.virtualbox.org/wiki/Documentation *for further and more detailed information.*

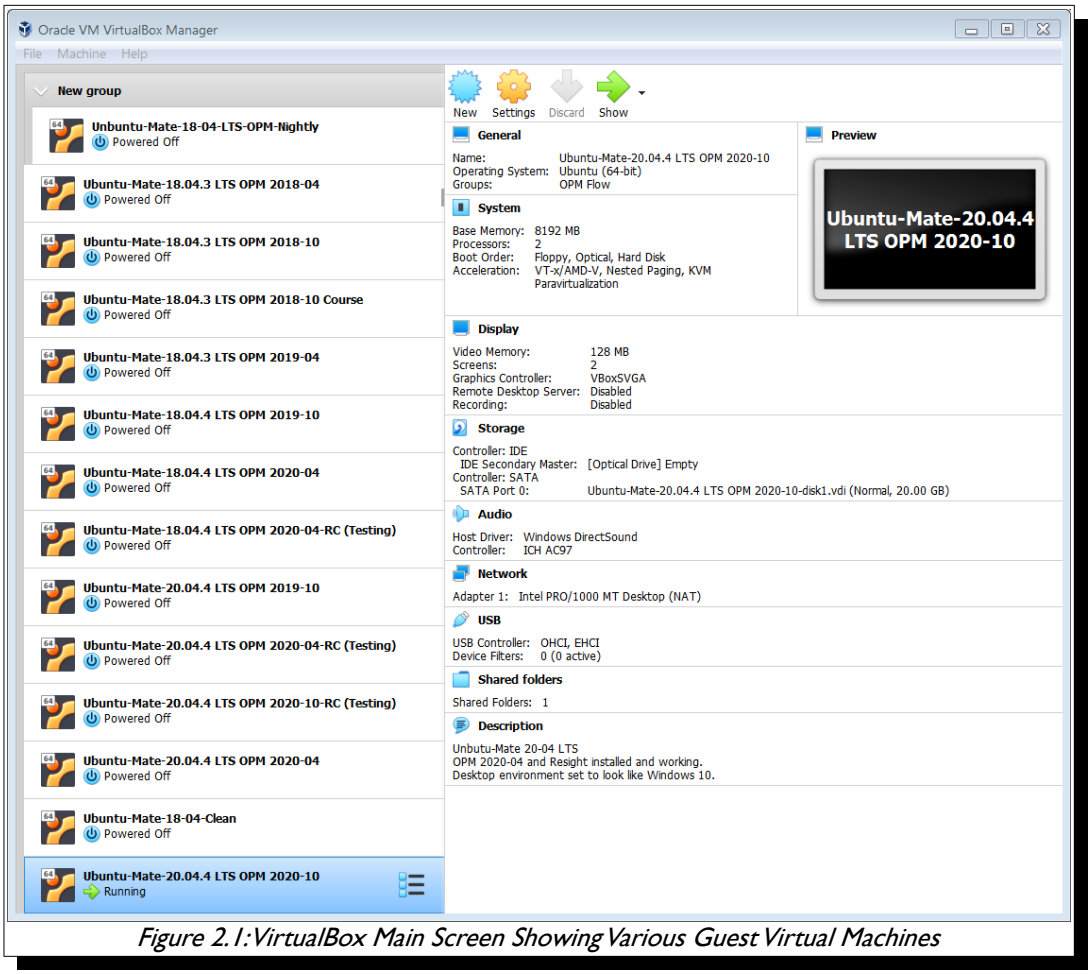

Figure 2.1: VirtualBox Main Screen Showing Various Guest Virtual Machines

- Then click the "New" icon button to install a new guest virtual machine.
- Identify the operating system type (Linux) and the Linux distribution that one wishes to install (Ubuntu 64-bit or RedHat for one of the CentOS distributions).
- Set the amount of RAM, should be 4GB or more; note the guest machine properties can subsequently be changed after the guest machine has been created.
- Create a virtual hard drive, the default virtual disk of VDI is normally used, and select either the dynamic or the fixed option. Next select the size of the virtual disk, the size should be sufficient to allow for the operating system and any other software, including OPM Flow, to be installed. For Ubuntu 20.04 LTS the operating system needs at least 10 GB. VirtualBox will then create the guest virtual machine.
- The next step is to start the guest virtual machine and installing the Linux operating system. This can be done by double clicking on the guest virtual machine and then selecting the previously downloaded IOS file. For Ubuntu 20.04 LTS the machine will boot into a live distribution, that is the guest virtual machine is running from a “live CD”, shown below.

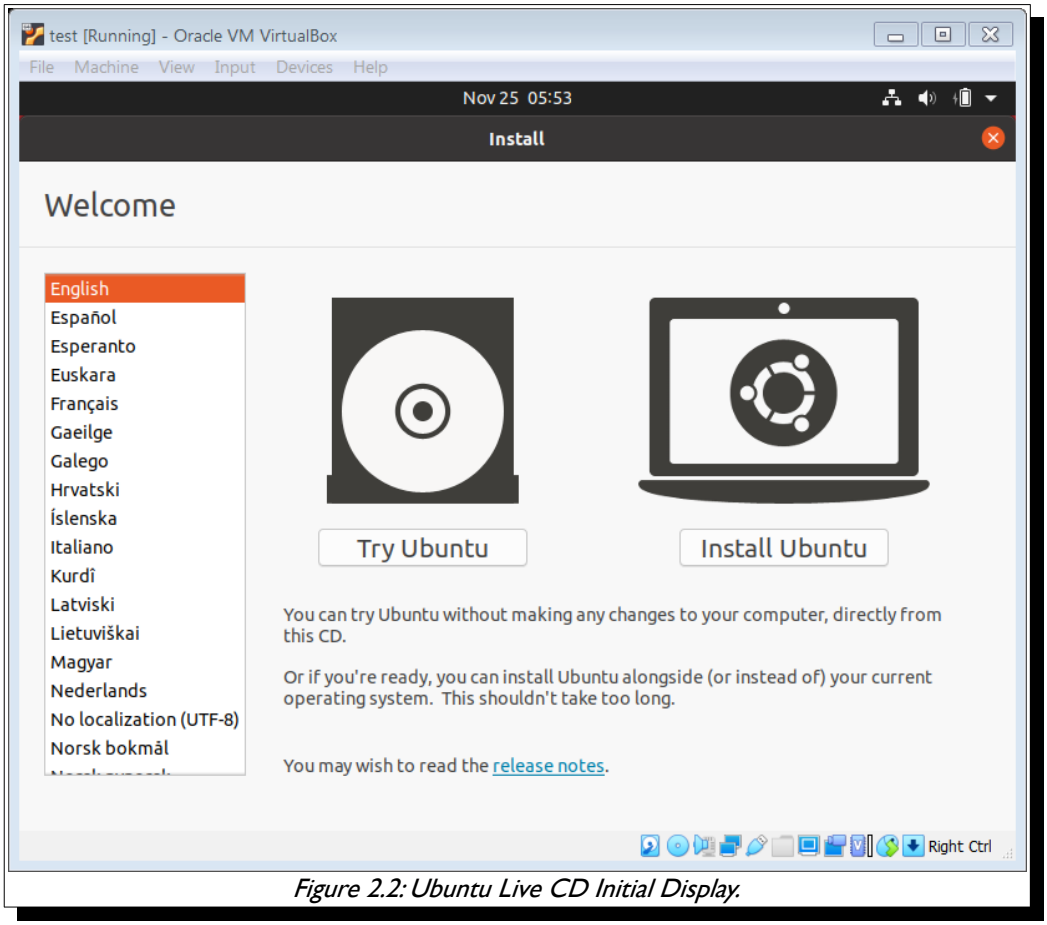

Figure 2.2: Ubuntu Live CD Initial Display.

- Select the "Install Ubuntu" option to install the operating system. The "Try Ubuntu" option means the guest machine will run from a "Live CD".
- Follow the on screen instructions to install the operating system, together with any updates suggested by the installer. Once the installation is complete the guest machine will re-boot as a normal guest Linux machine.

3) Installing OPM Flow in the Guest Virtual Machine.

- Boot up your virtual machine by selecting the machine and selecting the "Start" icon on the main VirtualBox screen (Figure 2.1). One should then be presented with the newly created guest virtual machine, similar to one shown in Figure 2.3, that displays the standard Ubuntu desktop.

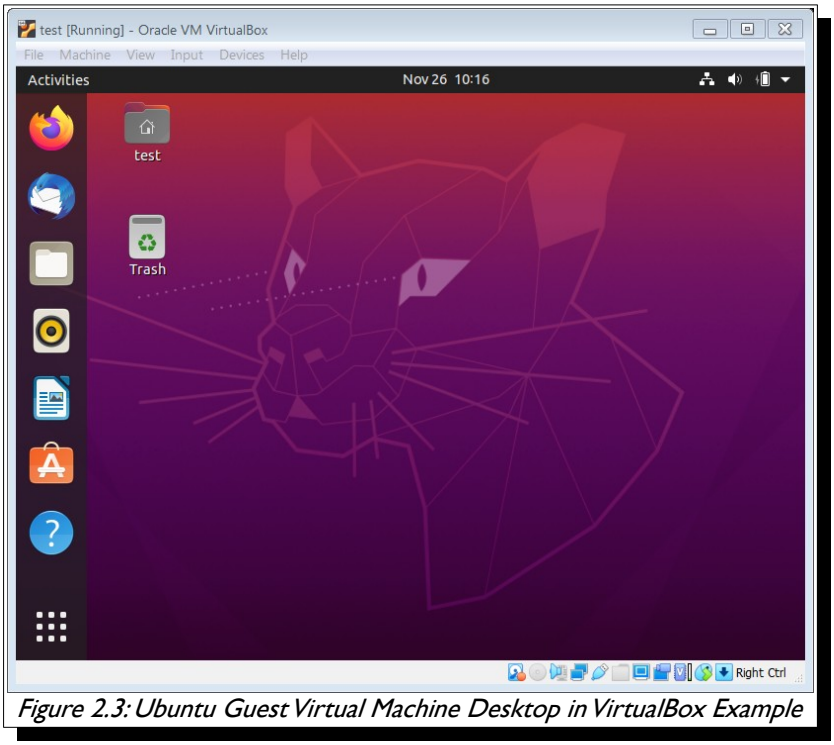

Figure 2.3: Ubuntu Guest Virtual Machine Desktop in VirtualBox Example

- In order to install OPM Flow in the guest virtual machine one first needs to open a command terminal using ALT+CNTL+T key sequence (Figure 2.4).

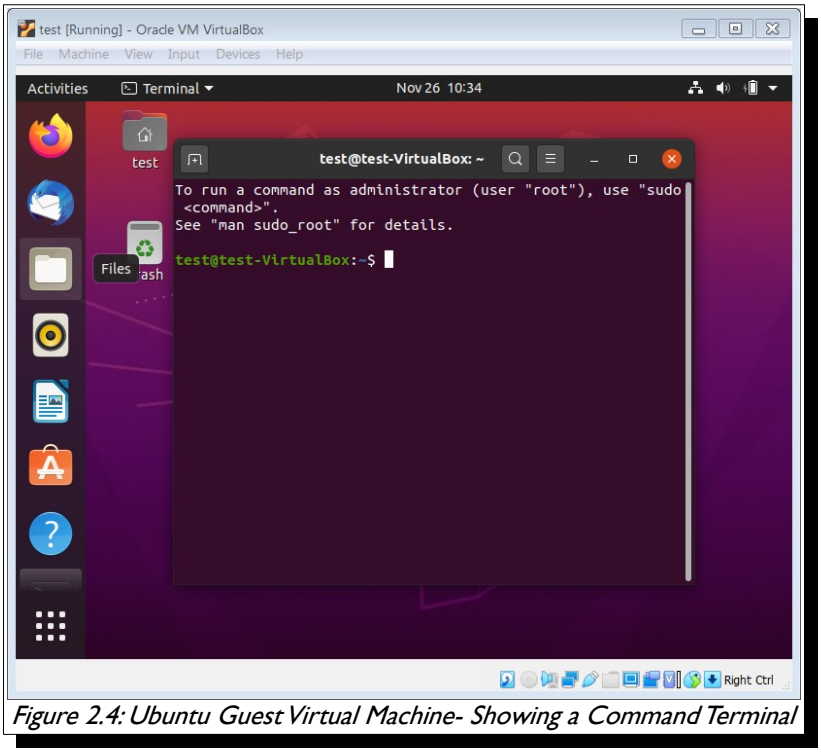

Figure 2.4: Ubuntu Guest Virtual Machine- Showing a Command Terminal

- One can then use the same commands as for a host machine, as described earlier in Sections *2.1.1 Ubuntu Linux 20.04 (64-bit version only) and Higher* and *2.1.2 Red Hat Enterprise or CentOS (version 6 or 7)* to install the software. To check if OPM Flow is installed, execute the following command in the terminal window:

```
flow --help
```

Which should then display the command line for the installed version of OPM Flow, as depicted in Figure 2.5

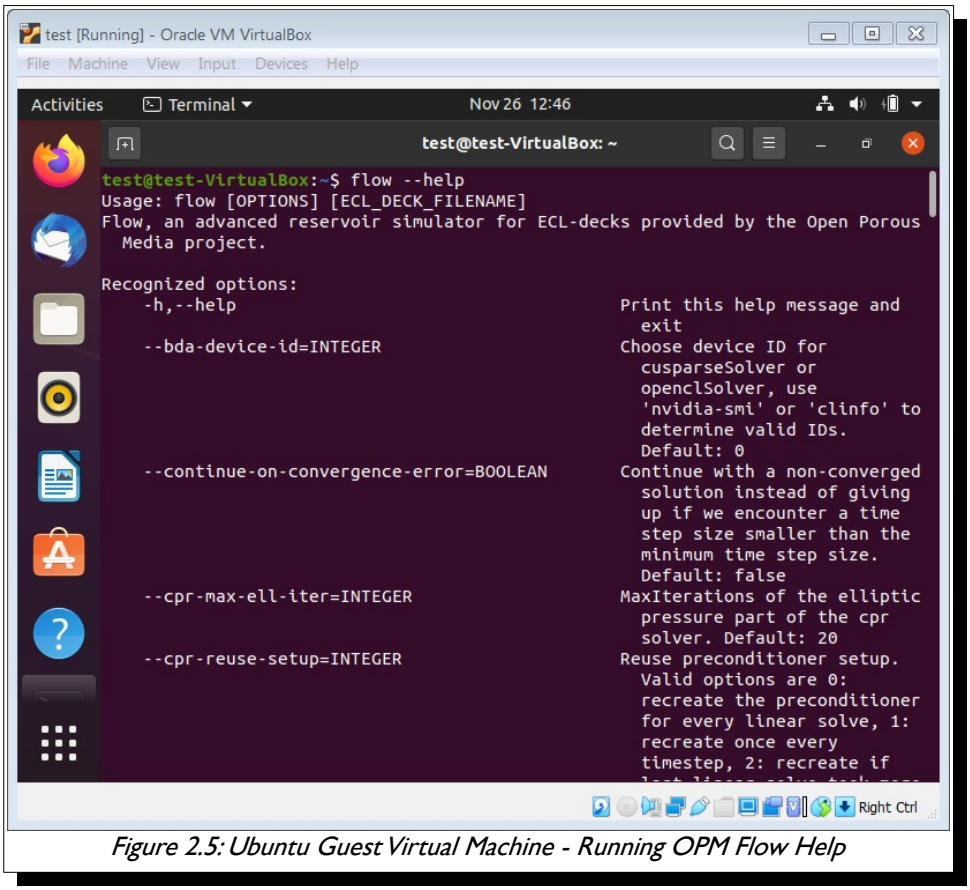

Figure 2.5: Ubuntu Guest Virtual Machine - Running OPM Flow Help

4) Using OPM Flow in a Linux Virtual Machine.

- The guest virtual machine only has access to files within the guest machine. To enable the guest to have access to the host machine files; on the main VirtualBox screen (Figure 2.1), select the "Setting" icon and then the "Shared Folders" option to set a share directory between the guest and the host machines. One can then have all the input and output files on the host machine and run OPM Flow in the guest virtual machine.
- Note one should shut down the guest virtual machine in the normal way to avoid potential file corruptions.
- One may also take snapshots of the current state of the virtual machine, as a form of backup if one changes the configuration of the virtual machine, or if one updates to the latest release of OPM Flow.

Historically this has been one of the preferred methods to run OPM Flow on Windows machines and still has several advantages, including being able to export and import various guest virtual machines for testing various versions of the simulator. However, Microsoft, with the introduction of Windows Subsystem for Linux ("WSL") have create a more seamless method for running OPM Flow on Windows 10 machines. This option is outlined in the next section.

2.1.4 WINDOWS 10 – WINDOWS SUBSYSTEM FOR LINUX

The first release of WSL was on August 2nd, 2016 and there has been various updates to this version which is known as WSL 1. On May 6th, 2019 WSL 2 was announced, that was a complete re-write of the Windows Subsystem for Linux, and offers significant performance improvements over WSL 1. Note that WSL 2 requires Windows 10 version 1903 or higher, with Build 18362 or higher, for x64 systems. WSL 2 is based on a virtual machine with an actual Linux Kernel that can immediately react to system calls. Such an architecture enables Full System call capabilities.

To run OPM Flow under WSL 1 or WSL 2 one has to first activate WSL, then install a Linux distribution from the Application store, and then finally install OPM Flow. The detail instruction are as follows:

1) Activating Windows Subsystem for Linux.

- On the Windows 10 machine, Click Start and navigate to Control Panel, then Select the Programs Category. Under Programs and Features, click on Turn Windows Features on or off and click the check box next to the Windows Subsystem for Linux option, to enable WSL.

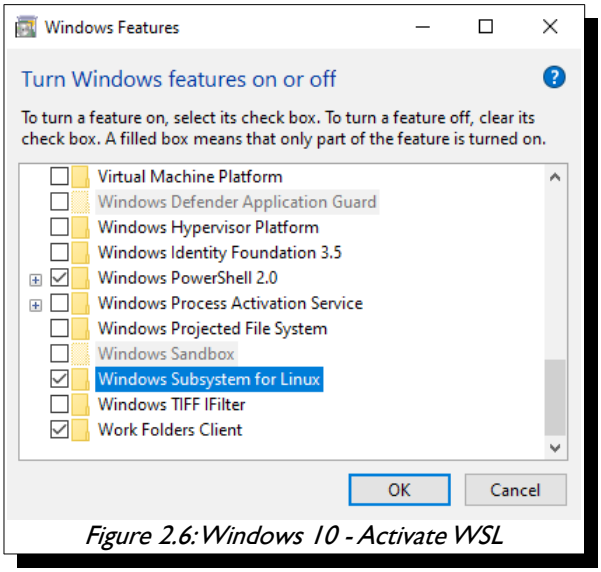

Figure 2.6: Windows 10 - Activate WSL

You may also have to ensure that CPU virtualization. has been activated in your computer's BIOS.

2) Installing a Linux Distribution.

- To install the Linux distribution in Windows 10, click Start and then select the Microsoft Store.
- Using the search box available in the Microsoft Store, pick one of the distributions that is compatible with OPM Flow (Figure 2.7).

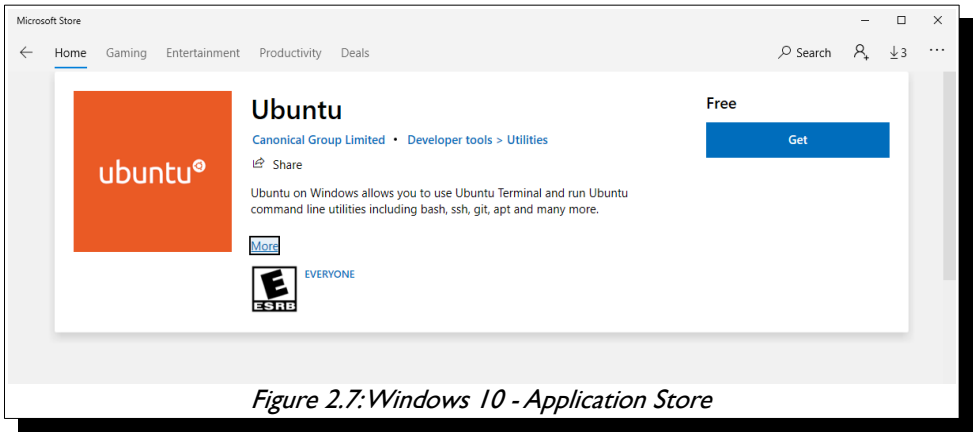

Figure 2.7: Windows 10 - Application Store

- After selecting the distribution, click Install or Get to install the Linux Distribution. Note the installer will ask you to sign into your account, but you can close the pop-up window if you don't want to sign in at this time.
- On completion of the installation process the Linux distribution will be installed on Windows 10 and ready for use. Furthermore, the distribution will be available directly in the Start Menu itself in the form of a standard everyday application (Figure 2.8).

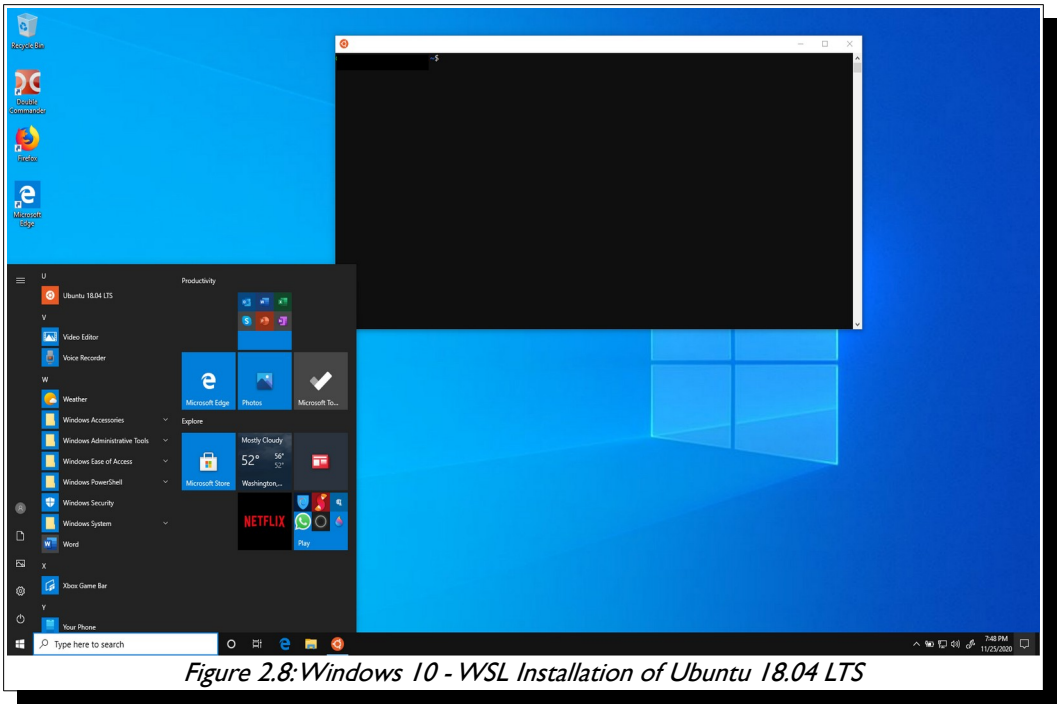

Figure 2.8: Windows 10 - WSL Installation of Ubuntu 18.04 LTS

- When starting the Linux Distribution for the first time, a brief setup process will take place. Basically, it will ask for the username and password you want to set for the Linux environment, a similar process as when you install a Linux distribution via VirtualBox.
- To check the version of WSL that will be used to run the Linux distribution, in PowerShell use the following command:

```
wsl -l -v
```

- To set the WSL for a given distribution, for example Ubuntu-22-04 to WSL 2, in PowerShell use the following command:

```
wsl --set-version Ubuntu-22-04 2
```

- And finally to set the default version for WSL for all Linux distributions, use the following PowerShell command:

```
wsl --set-default-version 2
```

3) Installing OPM Flow in a WSL Linux Distribution:

- Click on installed Linux distribution in the Start Menu to open a Linux terminal session, and then execute the Linux commands as described earlier in Sections *2.1.1 Ubuntu Linux 20.04 (64-bit version only) and Higher* and *2.1.2 Red Hat Enterprise or CentOS (version 6 or 7)* to install the software.

- To check if OPM Flow is installed, execute the following command in the Linux terminal window:

```
flow --help
```

Which should then display the command line for the installed version of OPM Flow, as depicted in Figure 2.9.

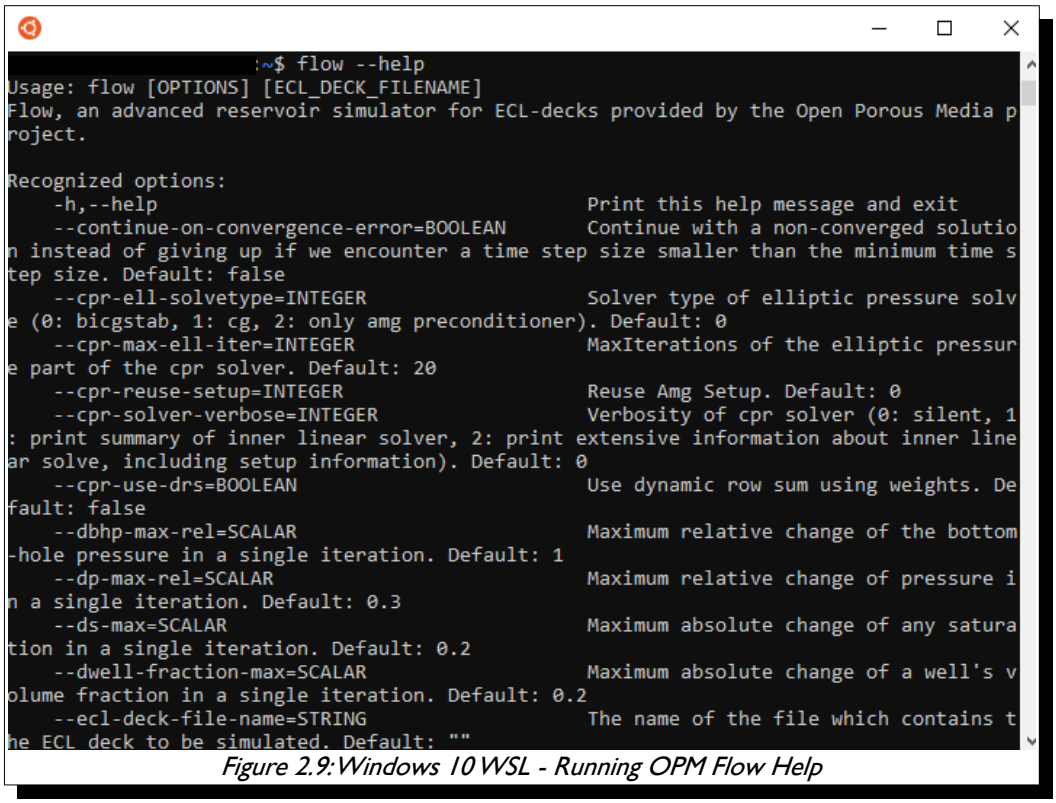

Figure 2.9: Windows 10 WSL - Running OPM Flow Help

One can also use the Windows command terminal, instead of the WSL Linux Terminal, to do the same thing by adding WSL character string before the command, that is:

```
wsl flow --help
```

4) Using OPM Flow via the Windows 10 WSL Linux Virtual Machine.

- Similar to running OPM Flow using a Linux distribution installed in VirtualBox, the WSL Linux virtual machine only has access to files within WSL virtual machine. To access the Windows 10 file system, one has to execute the Linux CD command in the WSL Linux Terminal, the command has the form:

```
cd /mnt/<drive letter>
```

For example, to access the Windows 10 system drive C one would use the following command:

```
cd /mnt/c
```

One can then run OPM Flow from the desired directory in the WSL Linux virtual machine and use OPM ResInsight under Windows 10 to view the results of the simulation run.

User experience indicates this approach of running OPM Flow under Windows 10 is the most integrated and convenient method, compared to the VirtualBox approach, especially for the less technically advance users.

2.1.5 USING A DOCKER CONTAINER

See the tutorial on the OPM website *Running Flow in Docker.*

2.1.6 INSTALLING FROM SOURCE

See instructions on the OPM website *Building from Source*.

2.2 RUNNING OPM FLOW 2023-10 FROM THE COMMAND LINE

This section describes how to run the OPM Flow simulator and the various command line options associated with this release, the command line syntax for running OPM Flow is:

```
flow [OPTIONS] CASENAME
```

and typing the following command from your terminal:

```
flow CASENAME
```

will start the simulator and run the case specified by CASENAME.DATA. Alternatively, you can type the path to the binary and the *.DATA file, as per the example below:

```
path_to_binary/flow path_to_data/CASENAME
```

The simulator can also be run using command line parameters for example to run the previous CASENAME one could use:

```
flow --ecl-deck-file-name=path_to_data/CASENAME
```

Note that there must be no spaces around the equals sign and there should be no spaces in CASENAME. If there are spaces in CASENAME, which can typically occur on Windows based systems, then the CASENAME should be enclosed in quotes; thus instead of CASE NAME use "CASE NAME".

By default output files are generated in the same folder as the *.DATA file. To override this one can use the --output-dir command line parameter, for instance:

```
flow --output-dir=foo CASENAME
```

will send the output files to the foo directory.

It is also possible to put multiple command line options together in a parameter file. To do so, put one option on each line of the file with ".param" as the extension and pass that filename as a command line parameter to OPM Flow using:

```
flow --parameter-file=CASENAME.PARAM
```

to instruct OPM Flow to read the parameter file. Note, it is good practice to name both the *.DATA and parameter file with the same CASENAME, to avoid confusion. However, if one wishes to use the same parameter file for various cases one can use the same parameter file followed by the DATA file, for example:

flow –-parameter-file=path_to_data/CASENAME.param CASENAME.DATA

If OPM Flow is installed with parallel capabilities then:

```
mpirun -np 4 flow --parameter-file=path_to_data/CASENAME.param
```

will start OPM Flow on four nodes etc.

Note

On Red Hat based distributions, including centOS distributions, one needs to install the openmpi version of the simulator, opm-simulators-openmpi-bin, via:

sudo yum install opm-simulators-openmpi-bin

and then set the MPI version to use. The way this is done is by first making the module command available, by running the following command:

. /usr/share/Modules/init/bash

Then query for the installed modules with:

module avail

And lastly, you tell the system it to use openmpi with:

module add mpi/openmpi-x86_64

On Ubuntu based distributions, there is no need for this as openmpi is installed and mpirun just works.

A complete list of the active user facing command line options and their function is given in the Table 2.1 for the current release. These commands are the options listed with command line --help option, there is also a --help-all option that lists all the command line options included in the release, including experimental, obsolete, hidden and deprecated options.

OPM Flow release 2018-10 and beyond now use the eWoms/ebos[35] command line interface; whereas, previous releases used the OPM Flow specific command line parameters and are documented in section *APPENDIX E: RUNNING PREVIOUS RELEASES OF OPM FLOW* for reference.

Additional tutorials for running OPM Flow is available on OPM website in the *Tutorials* section.

OPM Flow 2023-10 Command Line Options

No.	Variable Name	Description	Default
1	-h or --help	A character string that causes OPM Flow to print a help message that gives a brief description of the available command line parameters. **This now only prints the active user facing command line options.**	N/A
2	--help-all	Prints all the command line options included in the release, including obsolete, hidden and deprecated options.	N/A
3	--accelerator-mode	Choose a linear solver, usage: '—accelerator-mode=[none | cusparse | opencl | amgcl | rocalution]'.	"none"
4	--allow-distributed-wells	Allow the perforations of a well to be distributed to interior of multiple processes.	false
5	--alternative-well-rate-init	Use alternative well rate initialization procedure.	true
6	--bda-device-id	Choose device ID for cusparseSolver or	0

[35] *eWorms is a C++ software framework concerned with fully-implicit numerical models for flow and transport in porous media. It it is developed as an integral part of the Open Porous Media (OPM) initiative.*

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		openclSolver, use 'nvidia-smi' or 'clinfo' commands to determine valid IDs.	
7	--continue-on-convergence-error	Continue with a non-converged solution instead of giving up if we encounter a time step size smaller than the minimum time step size.	false
8	--cpr-reuse-interval	A positive integer that sets the reuse preconditioner interval. Used when *--cpr-reuse-setup* is set to 4, then the preconditioner will be fully recreated instead of reused every N linear solve, where N is this parameter.	30
9	--cpr-reuse-setup	A positive integer that defines if the CPR solver should re-use the AMG setup. Valid options are: 0 : Recreate the preconditioner for every linear solve. 1 : Recreate once every time step. 2 : Recreate if last linear solve took more than 10 iterations. 3 : Never recreate. 4 : Recreate every N linear solves, where N is the parameter *--cpr-reuse-interval*. Changed the default value from three to four.	4
10	--dbph-max-rel	A real positive value that sets maximum relative change of the bottom-hole pressure in a single iteration	1.0
11	--dp-max-rel	A real positive double precision value that sets the maximum allowed relative change of pressure per iteration.	0.3
12	--ds-max	A real positive double precision value that sets the maximum allowed change in saturation per iteration.	0.2
13	--dwell-fraction-max	A real positive value that sets the maximum allowed change in well's volume fraction per iteration.	0.2
14	--ecl-deck-file-name	A character string that defines the name of the OPM Flow input file which contains the simulator's ECLIPSE formatted input deck to be simulated. Note that there must be no spaces in the filename. If there are spaces, which can typically occur on Windows based systems, then the filename should be enclosed in quotes; thus instead of FILE NAME use	""

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		"FILE NAME".	
15	--ecl-enable-drift-compensation	A Boolean value set to true or false that enables (true) or disables (false) partial compensation of systematic mass losses via the source term of the next time step.	true
16	--ecl-enable-tuning	Honor some aspects of the TUNING keyword from the ECL deck.	false
17	--ecl-newton-relaxed-tolerance	The maximum error which the volumetric residual may exhibit if it is in a 'relaxed' region during a strict iteration.	1e+09
18	--ecl-newton-relaxed-volume-fraction	The fraction of the pore volume of the reservoir where the volumetric error may be voilated during strict Newton iterations.	0.03
19	--ecl-newton-strict-iterations	The number of Newton iterations where the volumetric error is considered.	8
20	--ecl-newton-sum-tolerance	The maximum error tolerated by the Newton method for considering a solution to be converged.	0.0001
21	--ecl-newton-sum-tolerance-exponent	The the exponent used to scale the sum tolerance by the total pore volume of the reservoir.	0.333333
22	--ecl-output-double-precision	A Boolean value set to true or false that switches on (true) or off (false) double precision in restart files. Useful for 'perfect' restarts.	false
23	--ecl-output-interval	An integer value defining the number of report steps that ought to be skipped between two writes of restart files results.	-1
24	--edge-weights-method	A defined positive integer value that defines the edge-weighing strategy: 0 : For uniform, 1 : for trans, or 2 : for log(trans).	1
25	--enable-adaptive-time-stepping	A Boolean value set to true or false that turns on (true) or off (false) adaptive time stepping. If set to false the report time steps provided by the input deck are used.	true
26	--enable-async-ecl-output	A Boolean value set to true or false that sets the output mode to be asynchronously (true), letting the simulator continue computing the next time step while writing results to restart and summary files in the commercial simulators format.	true
27	--enable-async-vtk-output	A Boolean value set to true or false that sets the output mode to be asynchronously	true

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		(true), letting the simulator continue computing the next time step while writing results to the VTK output files.	
28	--enable-dry-run	A Boolean value set to true or false that specifies if the simulation should actually run, (true) or just check the input deck (false). This option is equivalent to activating the NOSIM keyword in the RUNSPEC section of the input deck (see section *5.3.97 NOSIM – Activate the No Simulation Mode for Data File Checking*). The default value of "auto' will use whatever is stipulated in the input deck via the NOSIM keyword.	"auto"
29	--enable-ecl-output	A Boolean value set to true or false that specifies if the binary output files (restart, summary files, etc.) should be written in the commercial simulator's format (true), or OPM Flow's format (false).	true
30	--enable-esmry	A Boolean value that switches on (true) or off (false) the output SUMMARY vectors to the ESMRY file for fast loading of summary data.	false
31	--enable-gravity	A Boolean value that switches on (true) or off (false) the use of the gravity correction for the pressure gradients.	true
32	--enable-grid-adaptation	A Boolean value that enables (true) or disables (false) adaptive grid refinement/coarsening.	false
33	--enable-intensive-quantity-cache	A Boolean value that switches on (true) or off (false) the caching of intensive quantities.	true
34	--enable-logging-fallout-warning	A Boolean value set to true or false that sets the developer option to see whether logging was on non-root processors (true). If set to true output will be appended to the *.DBG or *.PRT files.	false
35	--enable-opm-rst-file	A Boolean value set to true or false to write OPM specific data sets to the commercial simulators restart file to enable restart of an OPM Flow runs (true) by OPM Flow, or not to write the data (false).	false
36	--enable-storage-cache	A Boolean value set to true or false that turns on (true) or off (false) storing previous storage terms and avoid re-calculating them.	true
37	--enable-terminal-output	A Boolean value set to true or false that	true

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		turns on (true) or off (false) high-level information about the simulation's progress to the terminal	
38	--enable-thermodynamic-hints	A Boolean value that enables (true) or disables (false) thermodynamic hints.	false
39	--enable-tuning	A Boolean value set to true or false that instructs OPM Flow to read the time stepping parameters from the *TUNING - Numerical Tuning Control* keyword in the input deck, if set to true. Note that only the first record of the TUNING keyword is processed.	false
40	--enable-vtk-output	A Boolean value set to true or false that turns on (true) or off (false) a global switch for writing VTK files.	false
41	--enable-well-operability-check	A Boolean value set to true or false that enables (true) checking of a well's operating status, or disables (false) the checking.	true
42	--enable-well-operability-check-iter	A Boolean value set to true or false that enables (true) checking of a well's operating status during iterations, or disables (false) the checking during iterations.	false
43	--enable-write-all-solutions	A Boolean value set to true or false that turns on (true) or off (false) the writing of all solutions to disk instead of only the ones for the report steps.	false
44	--end-time	The simulation time at which the simulation is finished [s].	1e+100
45	--force-disable-fluid-in-place-output	A Boolean value set to true or false that instructs OPM Flow not to print the Fluid In-Place report after each report time step (true) or not (false). Note this parameter will override the print request in the input deck.	false
46	--force-disable-resv-fluid-in-place-output	A Boolean value set to true or false that instructs OPM Flow to not to print the Reservoir Volume Fluid In-Place report after each report time step (true) or not (false). Note this parameter will override the print request in the input deck.	false
47	--full-time-step-initially	A Boolean value set to true or false that instructs OPM Flow to always attempt to finish a report step using a single time step (true) or not (false).	false

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
48	--ignore-keywords	A character string that defines a list of keywords which should be ignored by OPM Flow. The keyword string should be enclosed in quotes and each keyword separated by a colon, that is ':' .	""
	ILU Preconditioner Parameters		
49	--ilu-fillin-level	A positive integer value that sets the fill in level for the ILU preconditioner.	0
50	--ilu-redblack	A Boolean value set to true or false that instructs OPM Flow to use red-black partitioning for the ILU preconditioner. (true) or not (false).	false
51	--ilu-relaxation	A real positive double precision value that sets the relaxation factor of the linear solver's ILU preconditioner	0.9
52	--ilu-reorder-spheres	A Boolean value set to true or false that specifies OPM Flow to reorder the entries of the matrix in the red-black ILU preconditioner in spheres starting at an edge (true) or not (false) If false the original ordering is preserved in each color. Otherwise try to ensure D4 ordering (in a 2D structured grid, the diagonal elements are consecutive).	false
53	--initial-time-step-in-days	A real double precision value that sets the size of initial time step in days.	1.0
54	--initial-time-step-size	A real double precision value that sets the size of initial time step in seconds.	86400
	Linear Solver Parameters		
55	--linear-solver	A defined quoted character string that sets the configuration of the linear solver, valid values are: 1) ilu0 (default), 2) cprw or cpr (an alias for cprw),[36] [37] and [38] 3) cpr_quasiimpes, 4) cpr_trueimpes, 5) amg,[39] 6) hybrid (experimental), or	"ilu0"

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		7) a file name that has the extension ".json", that contains the linear solver configuration parameters. Option (2) extends the existing Constrained Pressure Residual ("CPR") preconditioner to include wells. This option can also be invoked via the CPR keyword in the RUNSPEC section; however, the command line parameter takes precedence. For option (7) one enters a character string enclosed in quotes that defines the filename of a JSON configuration file for the flexible linear solver system. In this case the file extension should be '.json'. Note that the *.PRT file contains the "Property tree for the linear solver" listing, which is the JSON specification of the current case, and can be used to configure a user specific linear solver JSON file. The option "cpr" now is an alias for "cprw" instead of "cpr_trueimpes".	
56	--linear-solver-ignore-convergence-failure	A Boolean value set to true or false that if set to true convergences failures in the linear solver are ignored. This option should be used with care, as the results might be unreliable.	false
57	--linear-solver-max-iter	A positive integer value that defines the maximum number of linear iterations.	200
58	--linear-solver-print-json-definition	Write the JSON definition of the linear solver setup to the DBG file.	true
59	--linear-solver-reduction	A real positive double precision value that sets the minimum reduction of the residual for the linear solver. The linear solver convergences when the residual is reduced sufficiently. **The simulator now overrides the default reduction to be 0.005 instead of 0.01, if the linear solver has been set to one of the cpr options, in a similar manner as how the default maximum number of linear iterations for the cpr and cprw options are changed to 20 instead of 100, unless specified by the command line option by the user.**	0.01
60	--linear-solver-restart	A positive integer value that sets the number of iterations after which GMRES is restarted.	40

[39] *M. Blatt, A parallel algebraic multigrid method for elliptic problems with highly discontinuous coefficients, Ph.D. thesis, Ruprecht-Karls-Universität Heidelberg (2010).*

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
61	--linear-solver-verbosity	A positive integer value that defines the output from linear solver: 0 : No extra output, 1 : output per solution iteration, or 2 : output per iteration.	0
62	--load-file	A character string enclosed in quotes that defines the FileName for the .OPMRST file used to load the serialized state. If empty, CASENAME.OPMRST is used.	""
63	--load-step	An integer value that determines if the simulator should load the serialized state from OPM Flow's version of the restart file. and should be set to either a specific report step, or 0 to load the last stored report step. The default value of -1 does not load the data from the OPM Flow specific restart file. OPM Flow's version of the restart file, is written using the *--save-step=N* option.	-1
64	--local-domains-ordering-measure	A character string enclosed in quotes that defines the subdomain ordering measure. Allowed values are 'pressure' and 'residual'.	"pressure"
65	--local-domains-partitioning-imbalance	A real positive double precision value that sets the subdomain partitioning imbalance tolerance. 1.03 is 3 percent imbalance.	1.03
66	--local-domains-partitioning-method	A character string enclosed in quotes that defines the subdomain partitioning method. Allowed values are 'zoltan', 'simple', and the name of a partition file ending with '.partition'.	"zoltan"
67	--local-solve-approach	A character string enclosed in quotes that defines the local solve approach. Valid choices are 'jacobi' and 'gauss-seidel'.	"jacobi"
68	--local-tolerance-scaling-cnv	A real positive double precision value that sets the convergence tolerance for local solves. Set to lower than 1.0 to use stricter convergence tolerance for local solves.	0.01
69	--local-tolerance-scaling-mb	A real positive double precision value that sets the convergence tolerance for local solves. Set to lower than 1.0 to use stricter convergence tolerance for local solves.	1
70	--local-well-solve-control-switching	A boolean value that allows (true) or disallows (false) control switching during local well solutions.	false
71	--matrix-add-well-contributions	A Boolean value set to true or false that if set to true explicitly specifies the influences	false

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		of wells between cells in the Jacobian and preconditioner matrices.	
72	--max-inner-iter-ms-wells	A positive integer value that defines the maximum number of inner iterations for multi-segment wells.	100
73	--max-inner-iter-wells	A positive integer value that defines the maximum number of inner iterations for standard wells.	50
74	--max-local-solve-iterations	A positive integer value that defines the maximum number of iterations for local solves with NLDD nonlinear solver.	20
75	--max-newton-iterations-with-inner-well-iterations	A positive integer that specifies the maximum newton iterations with inner well iterations.	8
76	--max-pressure-change-ms-wells	A real positive value that defines the maximum relative pressure change for a single iteration of the multi-segment well model.	1.0×10^6
77	--max-residual-allowed	A real positive value that sets the absolute maximum tolerance for residuals without cutting the time step size.	1.0×10^7
78	--max-single-precision-days	A real positive value that sets the maximum time step size where single precision floating point arithmetic can be used for solving the linear systems of equations.	20.0
79	--max-temperature-change	A real positive value that stipulates the maximum absolute change of temperature in a single iteration.	5
80	--max-time-step-divisions	A positive integer that specifies the maximum number of divisions by two of the timestep size before the simulation bails out.	10
81	--max-time-step-size	A real positive value that defines the maximum size to which all time steps are limited to in seconds.	inf
82	--max-welleq-iter	A positive integer that defines the maximum number of iterations to determine the solution to the well equations.	30
83	--maximum-number-of-well-switches	A positive integer values that stipulates the maximum number of times a well can switch to the same control.	3
84	--maximum-water-saturation	A real positive value that defines the maximum water saturation.	1.0
85	--milu-variant	A defined character string that specifies	"ILU"

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		which variant of the modified ILU preconditioner ought to be used. Possible variants are: 1) ILU (default, plain ILU), 2) MILU_1 (lump diagonal with dropped row entries), 3) MILU_2 (lump diagonal with the sum of the absolute values of the dropped row entries), 4) MILU_3 (if diagonal is positive add sum of dropped row entries. Otherwise subtract them), 5) MILU_4 (if diagonal is positive add sum of dropped row entries. Otherwise do nothing). The default is "ILU"	
86	--min-strict-cnv-ite	A positive integer that sets the minimum number of Newton iterations before relaxed tolerances are used for the CNV convergence criterion.	0
87	--min-time-step-based-on-newton-iterations	A real positive value that sets the minimum time step size (in days for field and metric unit and hours for lab unit) can be reduced to based on Newton iteration counts.	0.0
88	--min-time-step-before-shutting-problematic-wells-in-days	A real positive value that sets the minimum time step size in days for which problematic wells are not shut. Time steps below this value will result in problematic wells being shut-in by the simulator.	0.01
89	--min-time-step-size	A real positive value that sets the minimum size to which all time steps are limited to in seconds.	0.0
90	--network-max-iterations	A positive integer that sets the maximum number of iterations in the network solver before giving up.	200
91	--network-max-strict-iterations	A positive integer that sets the maximum iterations in network solver before relaxing tolerance.	100
92	--newton-max-error	A real positive value that sets the maximum error tolerated by the Newton method to which does not cause an abort.	1e+10
	Newton Solver Parameters		
93	--newton-max-iterations	A positive integer that defines the maximum number of Newton iterations per time step used by the simulator.	20
94	--newton-max-relax	A real positive value that sets the maximum	0.5

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		relaxation factor of a Newton iteration used by the simulator.	
95	--newton-min-iterations	A positive integer that sets the minimum number of Newton iterations per time step used by the simulator. The default value of one ensures that at least one Newton iteration is performed after the previous time step.	1
96	--newton-relaxation-type	A character string that defines the type of relaxation used in Newton's method, the default is dampen.	"dampen"
97	--newton-target-iterations	A positive integer that sets the 'optimum' number of Newton iterations per time step.	6
98	--newton-tolerance	A real positive value that sets the maximum raw error tolerated by the Newtonmethod for considering a solution to be converged.	0.01
99	--newton-verbose	A boolean value that specifies whether the Newton method should inform the user about its progress (true) or not (false).	true
100	--newton-write-convergence	A boolean value that specifies whether to write the convergence behaviour of the Newton method to a VTK file (true) or not (false).	false
101	--nldd-num-initial-newton-iter	A positive integer that sets the number of initial global Newton iterations when running the NLDD nonlinear solver.	1
102	--nonlinear-solver	A character string that specifies the nonlinear solver. Valid choices are newton or nldd.	"newton"
103	--num-local-domains	A positive integer that sets the number of local domains for NLDD nonlinear solver. Note this is an experimental feature in the current release 2023.10 that is expected to be more complete and tested by the 2024.10 release.	0
104	--num-pressure-points-equil	A positive integer that sets the number of pressure points (in each direction) in tables used for equilibration.	2000
105	--opencl-ilu-parallel	A Boolean value set to true or false that if set to true then parallelize the ILU decomposition and application on GPU, or not (false).	true
106	--opencl-platform-id	A positive integer that specifies the platform identification ("ID") for the	0

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		openSolver. Use the "clinfo" command to determine valid IDs.	
107	--output-dir	A character string that defines the directory to which OPM Flow is to write the commercial simulator compatible output files (restart, summary files etc.). The default value results in the files be written to the same directory as the input file.	""
108	--output-extra-convergence-info	A defined character string that specifies whether to provide additional convergence output to separate files for diagnostic purposes. The available options are: 1) "none" results in no extra output and overrides all other options. 2) "steps" writes out convergence information per time step, to a CASENAME.INFOSTEP file. The file is useful for identifying numerical issues. 3) "iterations" writes out non-linear convergence metrics, i.e., the MB and CNV values, per phase, for each non-linear iteration in each time step, to a CASENAME.*INFOITER* file. Options can be combined with commas, e.g."steps,iterations" for multiple outputs. The default value of "none" prevents the two files from being written out, for better compatibility with the commercial simulator.	"none"
109	--output-interval	A positive integer that specifies the number of report steps between two consecutive writes of restart data.	1

110	--output-mode	A defined character string that defines the output to the *.PRT and *.DBG files:
		1) "none": No output to the files.
		2) "log" or false: Output logging information only.
		3) "all" or true: Output everything.
		For example to just output logging information use:
		`--output-mode="log"`
		or
		`--output-mode=false`
			"all"

111	--owner-cells-first	A Boolean value set to true or false that determines if the cells owned by a rank should be ordered before ghost/overlapping the cells (true), or not (false).	true

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
112	--parameter-file	A character string that defines the name of a parameter file which contains the simulator's set of run-time parameters, as listed in this table.	""
113	--parsing-strictness	Set strictness of parsing process. Available options are: 1) "normal": stop for critical errors, and for unsupported keywords that would would change the simulator results if supported. 2) "high": stop for all errors, that is even for unsupported keywords that do not effect the results, for example ECHO and NOECHO. 3) "low": same as normal, except do not stop due to unsupported keywords that would change the simulator results if supported, and even if marked critical. Default: "normal"	"normal"
114	--predetermined-time-steps-file	A file with a list of predetermined time step sizes (one time step per line).	""
115	--pri-var-oscilation-threshold	A real positive value that defines the threshold value for the primary variable switching conditions after its meaning has switched to hinder oscillations.	1.0 x 10-5
116	--print-parameters	A positive integer value that request that the run time parameters be printed at the start of the run: 0 : No output to the files. 1 : Output *.DBG file. 2 : Output to *.DBG and *.PRT files (default).	2
117	--print-properties	A positive integer value that request that the compile time parameters be printed at the start of the run: 0 : No output to the files. 1 : Output *.DBG file. 2 : Output to *.DBG and *.PRT files (default).	2
118	--project-saturations	A Boolean value set to true or false that determines if all the fluid saturations should be scaled to ensure the values are in the interval (0, 1), including runs that use solvents (true), or not (false).	false
119	--regularization-factor-wells	A real positive value that defines the "regularization factor" for wells.	100

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
120	--relaxed-linear-solver-reduction	A real positive value that defines the minimum reduction of the residual which the linear solver need to achieve for the solution to be accepted.	0.01
121	--relaxed-max-pv-fraction	A real positive value that defines The fraction of the pore volume of the reservoir where the volumetric error (CNV) might be violated during strict Newton iterations.	0.03
122	--relaxed-pressure-tol-msw	A real positive value that sets the relaxation tolerance for the multi-segment well pressure solution in Pascals.	10000
123	--relaxed-well-flow-tol	A real positive value that sets the relaxation tolerance for the well flow residual in reservoir cubic metres (rm3).	0.001
124	--restart-time	A real positive value that sets the simulation time at which a restart should be attempted [s].	-1e+35
125	--restart-writing-interval	A positive integer value that sets the frequency at which time steps are serialized to disk.	16777215
126	--save-file	A character string that specifies the FileName for .OPMRST file used for saving serialized state. If empty, CASENAME.OPMRST is used.	""
127	--save-step	A character string that determines if the simulator should save the serialized state of the OPM Flow simulator at one or more report steps to a special *.OPMRST file. This is in addition to the normal restart files written, and consumes significantly more space than the normal restart files, but restarting OPM Flow from this file using the *--load-step* option deviates less from the original run, compared to restarting using the normal restart features. The files produced are not compatible with other simulators, and also will not be compatible between different releases of OPM Flow The parameter should be set to one of the following: 1) "all" to save all report steps, 2) ":x" to save every x'th step, or 3) "x" to save a specif time step. The default value of "" does not write anything to the OPM Flow specific restart file.	""
128	--scale-linear-system	A Boolean value set to true or false that	false

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		switches on (true) or off (false) the scaling of linear system of equations according to the equation scale and primary variable types.	
129	--sched-restart	A Boolean value that determines for a restart run if the case should initialize wells and groups from the historical SCHEDULE section (true), or from the well and group data on the restart file (false). Note that the commercial simulator always uses data from the restart file (false).	falsch
130	--serial-partitioning	A Boolean value that determines if partitioning for parallel runs on a single process (true), or not (false).	false
131	--shut-unsolvable-wells	A Boolean value that determines if the simulator should shut unsolvable wells (true), or not (false).	true
132	--solve-welleq-initially	A Boolean value set to true or false that determines if the simulator should fully solve the well equations before each iteration of the reservoir model (true), or not (false). Note that the well equations are always added to the full system and solved until converged.	true
	Solver Parameters		
133	--solver-continue-on-convergence-failure	A Boolean value that stipulates if the simulator should continue (true) instead of stopping (false) when the minimum solver time step is reached.	false
134	--solver-growth-factor	A real positive value that specifies the growth factor a time step can be increased by when recovering from one or more time step chops, subject to the maximum allowable time step size set by the *--solver-max-time-step-in-days* parameter. For example, if the current time step has converged at 5 days after a time step chop, and --solver-growth-factor is set to the default value of 2.0, then the next time step will be 2.0 * 5 days, that is at 10 days.	2.0
135	--solver-max-growth	A real positive value that specifies the maximum growth factor a time step can be increased by after a report time step. subject to the maximum allowable time step size set by the --solver-max-time-step-in-days parameter. Thus, if the current time step has converged at 5 days after at a report step,	3.0

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		and --solver-*max*-growth is set to the default value of 3.0, then the next time step will be 3.0 * 5 days, that is at 15 days.	
136	--solver-max-restarts	A positive integer that defines the number of allowed consecutive restarts (or time step chops) before the simulation is terminated.	10
137	--solver-max-time-step-in-days	A real positive double precision value that specifies the maximum allowed time step size in days.	365
138	--solver-min-time-step	A real positive double precision value that specifies the minimum size of a time step in days for field and metric units, and hours for laboratory units If a time step cannot converge without getting cut below this time step size the simulator will stop.	1.0×10^{-12}
139	--solver-restart-factor	A real positive double precision value that sets the time step chop factor of the time step after a convergence failure. For example, if the current non-convergent time step is 30 days and *--solver-restart-factor* is set to the default value, then the time step will be repeated using 0.33 * 30 days as the time step, that is 9.9 days.	0.33
140	--solver-verbosity	A positive integer that specifies the "chattiness" of the non-linear solver.	1
141	--strict-inner-iter-wells	A positive integer that specifies the number of inner well iterations with strict tolerance.	40
142	--strict-outer-iter-wells	A positive integer that specifies the number of newton iterations for which wells are checked with strict tolerance.	6
143	--temperature-max	A real positive value that sets the maximum absolute temperature.	1.0×10^{9}
144	--temperature-min	A real positive value that sets the minimum absolute temperature.	0
145	--threads-per-process	A positive integer value that stipulates the maximum number of threads to be instantiated per process ('-1' means 'automatic').	-1
	Time Stepping Control Algorithm Parameters		
146	--time-step-after-event-in-days	A real double precision value that sets maximum allowed time step after an event; for example, when a well is open or closed etc.	-1

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
		The default value of -1 means that events to do effect the time stepping.	
147	--time-step-control	A defined character string that defines the time stepping control algorithm and is set to one of the following: 1) pid: PID controller based adaptive time step control as suggested by Turek and Kuzmin[40]. 2) pid+iteration: Use PID and linear iteration numbers to guide the time step. 3) pid+newtoniteration: Use PID and non-linear iterations numbers to guide the time step. 4) Hardcoded: Use time steps supplied by user via the time-step-control-filename parameter.	"pid+newtoniteration"
148	--time-step-control-decay-damping-factor	A real positive value that specifies the decay rate a time step can be decreased by after the number target iterations has been exceeded	1.0
149	--time-step-control-decay-rate	A real positive value that specifies the decay rate a time step size can be decreased by after the number of target iterations has been exceeded	0.75
150	--time-step-control-file-name	A character string enclosed in quotes that specifies a filename where time steps are specified. The default is the character string timesteps For instance time steps can be generated by the ecl_summary application in libecl as per the following UNIX command line: `path_to_libecl_applications/ ecl_summary DECK TIME > filename` Where: DECK is the name of the data deck you want to get the time steps from, TIME tells the application to return the timing for the run, and "filename" is the name of the file the times are piped to.	"timesteps"
151	--time-step-control-growth-damping-factor	A real positive value that specifies the growth rate of the time step increase when the number of target iterations are undercut.	3.2

[40] *Algebraic Flux Correction III. Incompressible Flow Problems. Uni Dortmund, Turek and Kuzmin, January, 2006 (DOI: 10.1007/3-540-27206-2_8)*

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
152	--time-step-control-growth-rate	A real positive value that specifies the growth rate of the time step size when the number of target iterations are undercut.	1.25
153	--time-step-control-target-iterations	A positive integer that defines the number of linear iterations which the time step control scheme should aim for (if applicable).	30
154	--time-step-control-target-newton-iterations	A positive integer that specifies the number of Newton iterations which the time step control scheme should aim for (if applicable).	8
155	--time-step-control-tolerance	A real double precision value that sets the tolerance for PID (only used with the pid and pid+ options defined by the --time-step-control option).	0.1
156	--time-step-verbosity	A positive integer that specifies the "chattiness" during the time integration.	1
	Convergence and Material Balance Tolerance Parameters		
157	--tolerance-cnv	A real positive double precision value that specifies the maximum non-linear tolerance error. This is the local convergence tolerance (maximum of local saturation errors).	0.01
158	--tolerance-cnv-relaxed	A real positive value that defines the relaxed local convergence tolerance that applies for iterations after the iterations with the strict tolerance.	1.0
159	--tolerance-mb	A real positive double precision value that sets the maximum mass balance error, that is the tolerated mass balance error relative to total mass present.	1.0 x 10-6
160	--tolerance-pressure-ms-wells	A real positive double precision value that specifies the tolerance for the pressure equations for multi-segment wells.	1000
161	--tolerance-well-control	A real positive double precision value that sets the maximum tolerance for the well control equations.	1.0×10^{-7}
162	--tolerance-wells	A real positive double precision value that defines the maximum non-linear error for the well equations.	1.0×10^{-4}
163	-update-equations-scaling	A Boolean value that switches on (true) or off (false) the updating of the scaling factors for mass balance equations during the simulation.	false

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**
164	--use-average-density-ms-wells	A Boolean value that specifies whether to approximate segment densitities by averaging over the segment and its outlet (true) or not (false).	false
165	--use-gmres	A Boolean value that when set to true OPM Flow will use Generalized Minimal Residual ("GMRES")[41] and [42] solver instead of Biconjugate Gradient Stabilized ("BiCGSTAB")[43] and [44] as the linear solver within the Newton iterations.	false
166	--use-multisegment-well	A Boolean value that when set to true the simulator will use the well model for multi-segment wells instead of the one for single-segment wells.	true
167	--use-update-stabilization	A Boolean value set to true or false that switches on (true) or off (false) the stabilized Newton option, that attempts to detect and correct oscillations or stagnation during the Newton iterations. This option may improve convergence for some cases.	true
168	--water-only-threshold	A real positive value that defines the saturation threshold, for which cells with water saturations above or equal to this threshold are considered one-phase water only.	1.0
169	--zoltan-imbalance-tol	A real positive value that defines the tolerable imbalance of the load balancing provided by Zoltan package.	1.1
170	--zoltan-params	A character string that specifies the configuration of the Zoltan partitioner. Valid options are: graph, hypergraph or scotch. Alternatively, you can request a configuration to be read from a JSON file by giving the filename here, ending with '.json.' See https://sandialabs.github.io/Zoltan/ug_html/ug.html for available Zoltan options.	"graph"
Notes: 1) Cells colored green in the No. column are new command line parameters for this release. Similarly for the

OPM Flow 2023-10 Command Line Options			
No.	**Variable Name**	**Description**	**Default**

Default column, cells colored green indicate the default value has changed from the previous release.

2) Items shaded in gray are considered to be developer options that should be used with caution as the values associated with these command line parameters are subject to change.

3) VTK Graphics Command Line Parameters[45] set of commands are no longer listed via the basic help command line command:

```
flow --help
```

instead use:

```
flow --help-all
```

to get a list of supported command line Parameters.

4) The –enable-vtk-output option above, if set to "true" will write out the data as stipulated by the compile options. One may need to compile the source code to obtain the desired output.

5) As per all UNIX and LINUX based system the input is case dependent.

6) If a parameter file is used to set one of the above parameters, the leading "--" should not be incorporated in the parameter file.

Table 2.1: OPM Flow 2023-10 Command Line Options

As per all UNIX and LINUX based systems the input is case dependent. The command line parameters must either be entered as lower case or CamelCase, for example:

```
flow --enable-dry-run=false CASENAME.DATA
```

or:

```
flow --EnableDryRun=false CASENAME.DATA
```

If a parameter file is used to set one of the above parameters, the leading "--" should not be incorporated in the parameter file, for example on the command line use

```
flow --enable-dry-run=false CASENAME.DATA
```

but in the parameter file use:

```
ecl-deck-file-name=CASENAME.DATA

enable-dry-run=false
```

or:

```
EclDeckFileName=CASENAME.DATA

EnableDryRun=false
```

OPM Flow prints out the command line run time and compile time parameters in CamelCase in both the *.PRT and *.DBG files for reference, one can therefore use this as basis for creating additional run specific parameter files.

Note

It is worth considering having a parameter file for each run of the form CASENAME.param, in order to re-run a case and to use the same parameters for other cases.

[45] *Virtualization ToolKit ("VTK") files used to visualize the 3D results from the model using ParaView, an open-source, multi-platform general purpose data analysis and visualization application (https://www.paraview.org/overview/). For the commercial simulator's compatible output files OPM's ResInsight 3D visualization package can be used instead and is specifically tailored for OPM Flow and the commercial simulator.*

Example

The following example is taken for the Norne project and the comments in the example (preceded with "/#") explain the parameter setting used in the file.

```
# ------------------------------------------------------------------------
# INPUT AND OUTPUT OPTIONS
# ------------------------------------------------------------------------
#
# Input File
#
ecl-deck-file-name=NORNE_ATW2013.DATA
#
# Output and Output Directory
#
output-dir='\$HOME\OPM\NORNE\'
# ------------------------------------------------------------------------
# NEWTON SOLVER PARAMETER
# ------------------------------------------------------------------------
#
# Define Numerical Tolerances
#
tolerance-cnv=1e-2
tolerance-mb=1e-5
tolerance-wells=1e-2
#
# Set Min Newton Solver iterations to 1 and Max to 15
#
newton-min-iterations=1
newton-max-iterations=15
#
# ------------------------------------------------------------------------
```

Notice that the leading "--" have not be incorporated in the parameter file, as per the notes in Table 2.1.

In order to use the above parameter file called one would use the following format:

```
flow --parameter-file=CASENAME.PARAM
```

If the above parameter file was called NORNE_ATW2013.PARAM, then the command would be:

```
flow --parameter-file=NORNE_ATW2013.PARAM
```

or:

```
flow --ParameterFile=NORNE_ATW2013.PARAM
```

2.3 RUNNING OPM FLOW USING OPMRUN

This section briefly describes how to run the OPM Flow simulator using the Graphical User Interface ("GUI") program called OPMRUN, a more detailed description is given in *APPENDIX C: OPMRUN – FLOW JOB SCHEDULER*, that also describes the various tools included with OPMRUN. The program is written in Python 3 and has been tested under Ubuntu-Mate 20.04 TLS. The software can be downloaded from the following link:

https://github.com/OPM/opm-utilities/tree/master/opmrun

The intent is to develop a graphical user interface to OPM Flow that has similar functionality to the commercial simulator's program, with the targeted audience being Reservoir Engineers in a production environment. Developers and experienced Linux users will already have compatible work flows. OPMRUN enables the editing and management of OPM Flow's run time parameters, setting up job queues to run a series of simulation jobs sequentially, as well as the management of the job queues. Figure 2.10 shows the initial display.

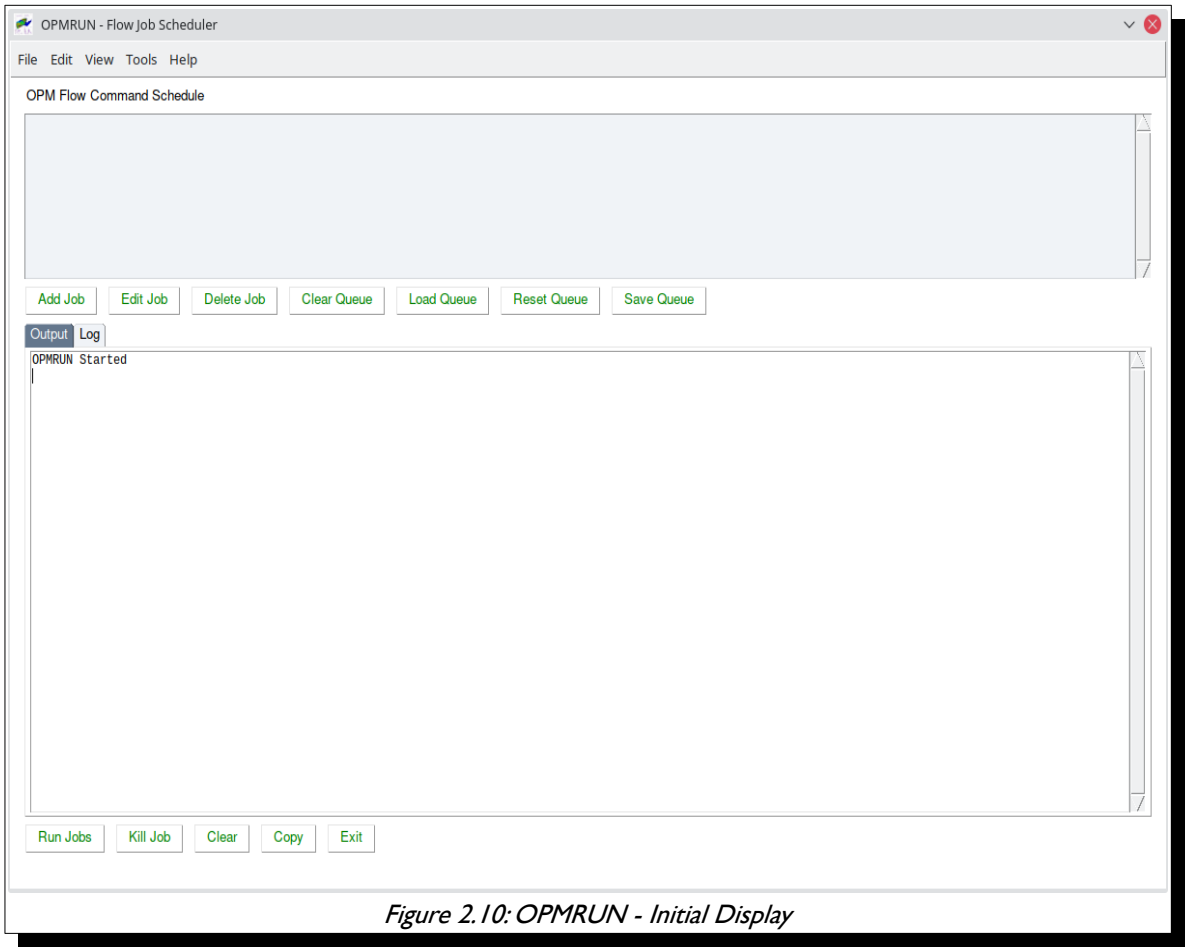

Figure 2.10: OPMRUN - Initial Display

Upon launch the program runs OPM Flow to get a list of command line parameters from the current version of OPM Flow. These default parameters can be edited for each case, or alternative default parameter sets can be loaded from an existing parameter file from another job, or a *.PRT file from a completed simulation.

As can be seen in Figure 2.11 the program has upper and lower display elements. The upper element shows a list of simulation jobs that are in the job queue and the lower element consists of two elements, one for the OPM Flow Output (the terminal output from OPM Flow) and a second element (OPM Run Log) that is a session log of the jobs run by OPMRUN. Clicking the OPM Flow Output and OPM Run Log tabs switches the display on the lowered element between two display types.

Figure 2.11: OPMRUN - Display Elements

To add jobs to the queue use the Add Job button or load an existing job queue using the Load Queue button. Jobs can be edited or deleted from the queue using the Edit Job and Delete Job buttons, and a series of jobs can be saved as a job queue by using the Save Queue button. The Clear Queue button deletes all jobs from the queue.

Pressing the Add Job button will display the following dialogue box:

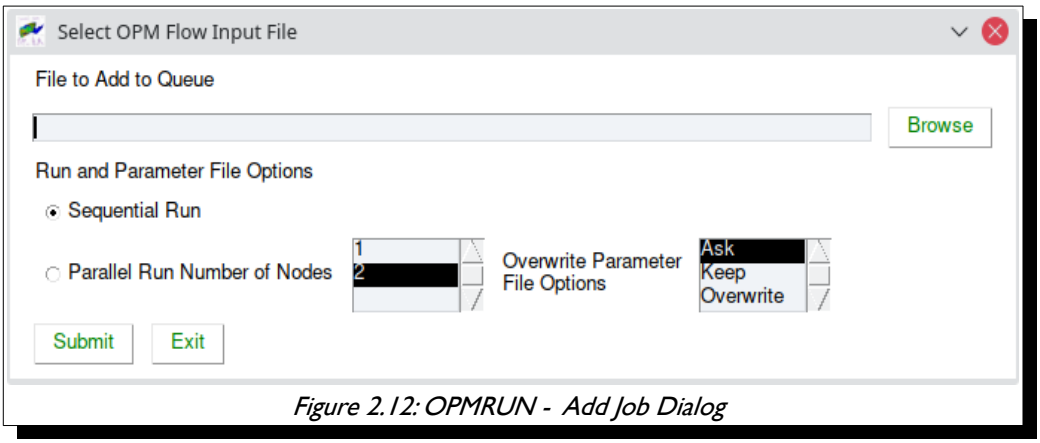

Figure 2.12: OPMRUN - Add Job Dialog

Use the *Browse* button to select the input file to add to the queue, then select the Run Parameters for this input file, then press the Submit button to add the input file to the job queue.

The Overwrite Parameter File Options allow for different default treatments of existing *.PARAM files, which is particularly useful when adding multiple jobs at the same time. The reason for this is because different versions of OPM Flow have different parameter sets and if a newer version of OPM Flow runs with a previous version's *.PARAM file then the simulator will stop with an error message for the various invalid

parameters for the current version of the simulator. To load a previously saved job queue, press the *Load Queue* button this will display a dialog box allowing the user to select a queue file (*.que), after pressing the *OK* button the jobs will be displayed in the Job List Element as illustrated in Figure 2.13.

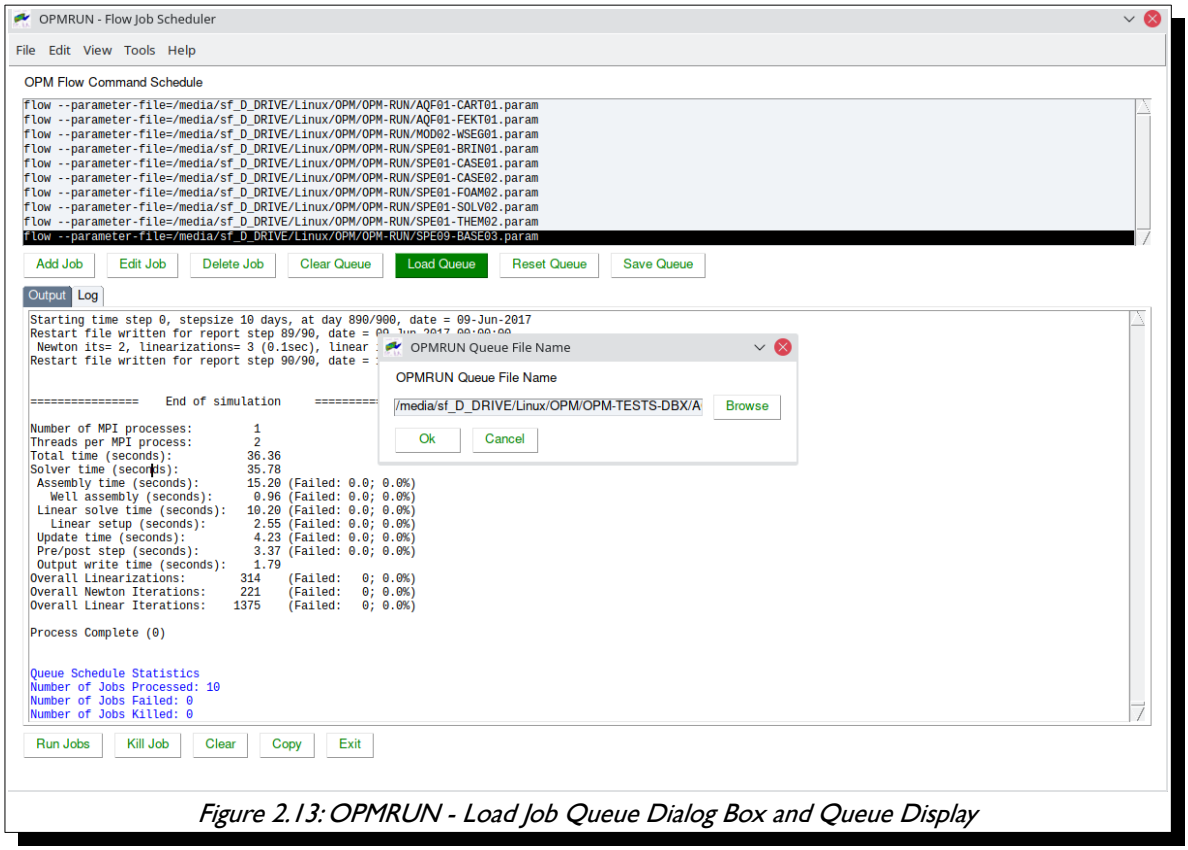

Figure 2.13: OPMRUN - Load Job Queue Dialog Box and Queue Display

Jobs in the queue can be edited by selecting the *Edit Job* button that will display two options: one to edit the input file using the defined editor and the second to edit the OPM Flow Parameter File. If the second option is selected OPMRUN will display a dialog box that shows a list of the OPM Flow command line parameters together with the parameter help information (Figure 2.14). Selecting a parameter from the list and selecting the Edit button will display the setting for the selected parameter (alternatively one can double click the required entry). One can then edit the parameter as required. Use the Save button to save the change and use the Exit but to save all the changes to the parameter file. The Cancel button will cancel all changes to the parameter file.

Alternatively one can use the:

1) Edit OPM Flow Parameter menu option to edit the parameter file for a job.
2) List OPM Flow Parameters menu option to list the commands in the parameter file for a job.
3) Set OPM Flow Default Parameters to set the default parameters for all subsequent jobs added to the queue. This option allows the user to load a default set of parameters from (1) OPM Flow, (2) an OPM Flow Parameter File, or (3) an OPM Flow print file (*.PRT).

One can also right-click on a job in the *Job List Element* and select one of the available options.

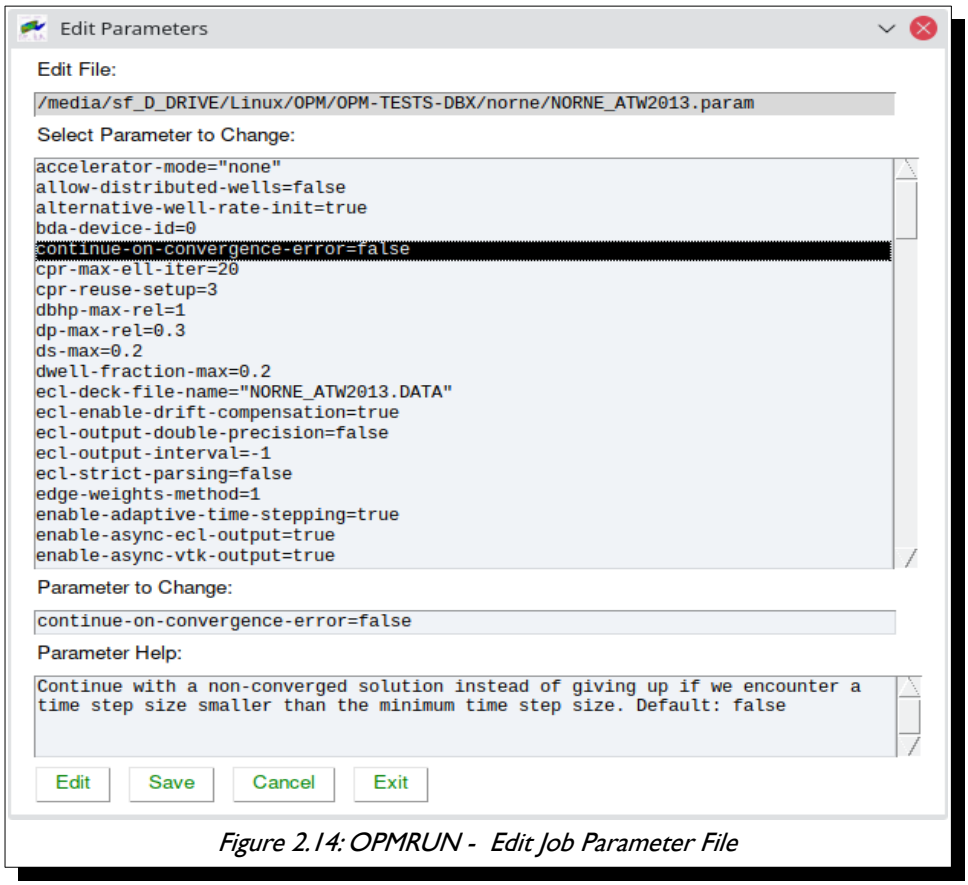

Figure 2.14: OPMRUN - Edit Job Parameter File

Selecting the *Run Jobs* button displays the Select Run Option dialog box shown in Figure 2.15.

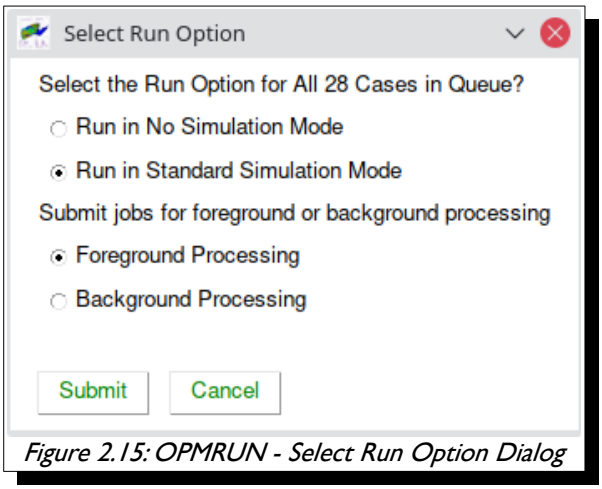

Figure 2.15: OPMRUN - Select Run Option Dialog

The Run in No Simulation Mode option is equivalent to setting the NOSIM option in the input deck for all jobs in the queue (see see section *5.3.97 NOSIM – Activate the No Simulation Mode for Data File Checking* and the –enable-dry-run command line parameter in Table 2.1 in section *2.2 Running OPM Flow 2019-04 From The Command Line*. This allows for checking all the jobs at once.

Selecting Run in Standard Simulation Mode will run all the jobs in the queue sequentially, with the OPM Flow terminal output directed to OPM Flow Output Element, as shown in Figure 2.16. The terminal output is also directed to a *.LOG file as well, similar to what the commercial simulator does.

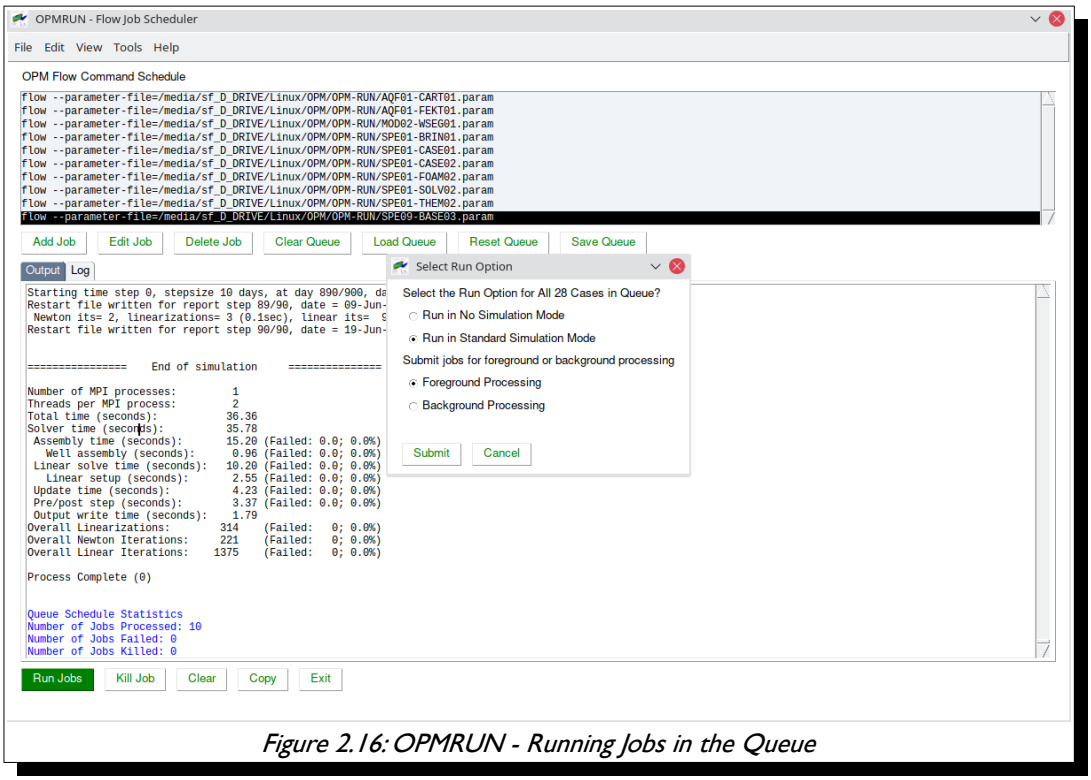

Figure 2.16: OPMRUN - Running Jobs in the Queue

Clicking the OPM Run Log tab displays the OPMRUN's session log file that records the time and date of the major events that have occurred, including the start and end times of each run. Notice also how OPMRUN deletes all the existing output files for a given job, if they exists, before running OPM Flow.

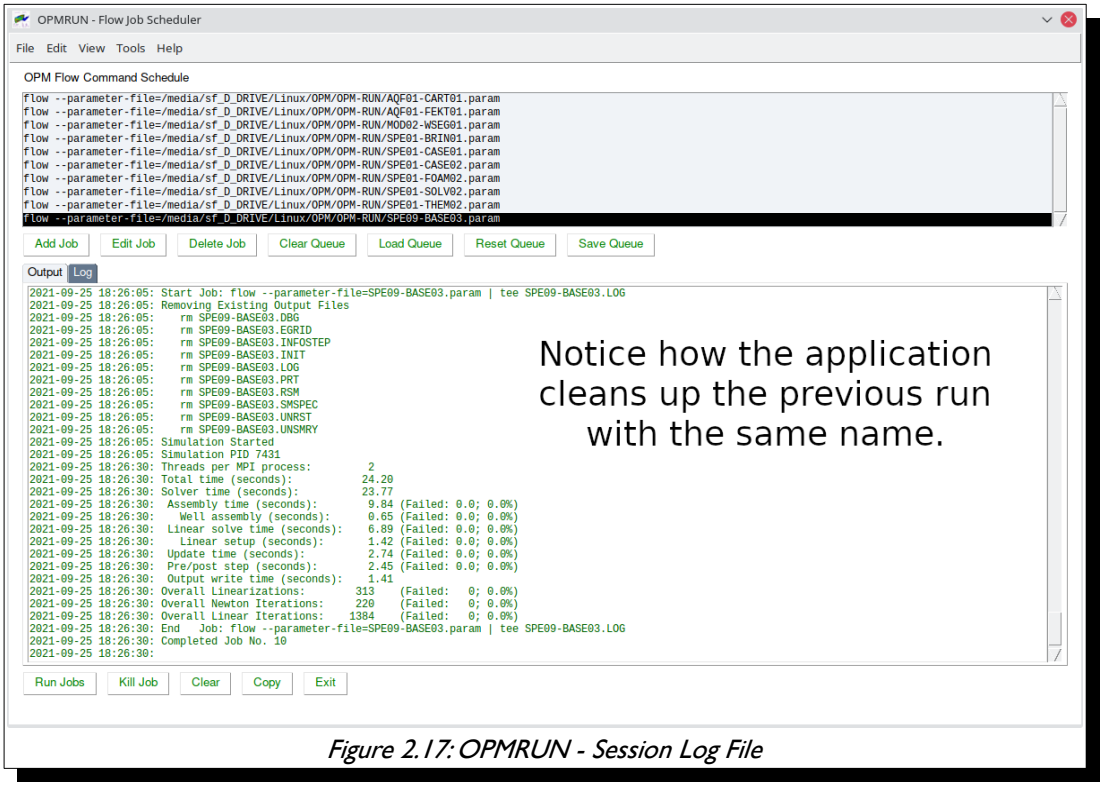

Figure 2.17: OPMRUN - Session Log File

The Kill button will ask the user if the current running job should be killed, and if the job is to be killed, the application will prompt as whether or not all the jobs in the queue should be killed.

The *Clear* clears the OPM Flow Output Element from the currently displayed tab (*Output* or *Log*) and the *Copy* button copies the data to the clipboard.

Finally, an example *.param file generated by OPMRUN for the 2022-10 release is shown below and on the following pages for reference:

In the above example, all the default parameters have be used.

In addition to the functionality described in this section, the application has various additional features accessible through the application's menus including:

1) Configuring OPMRUN various options, default editor, default terminal console for background jobs, setting default project directories, etc.

2) Various additional simulation input generation and conversion utilities are available including:

   - Compressing a job to save space (DATA, and all OPM Flow output files) and uncompressing previously compressed jobs.

   - Keywords, a keyword generator based on the Apache Velocity Template Language ("VTL"). The templates can therefore also be used with any editor that supports VTL, jEdit for example. There is one template per keyword, with the formatting the same as the OPM Flow manual. Over 450 templates are currently implemented. One can also customize the existing templates as well as creating User defined templates. The keywords are examples, one still has to edit the resulting deck with the actual required data, but the format with comments should make this a straight forward process.

   - A Production Schedule application that takes a comma delimited CSV file containing historical production and injection data and converts the data to an OPM Flow SCHEDULE file using the WCONHIST series of keywords. Currently only production data is supported.

   - Sensitivities application that generates sensitivity cases based on a "Base" case file. The Base file contains "Factors" (variable names), $X01, $X02, etc., that are substituted with user defined values using the data entered and the type of Sensitivity Scenario selected.

   - A Well Specification application that uses the standard well export files from OPM ResInsight to reformat the data in a more user-friendly manner for the WELSPECS and COMPDAT keywords. Optionally, the application can generate the COMPLUMP keyword based on the OPM ResInsight layers file, with one completion per defined reservoir layer.

   - Calling OPM ResInsight and loading the currently selected job into OPM ResInsight for viewing.

   - A Well Trajectory Conversion application that converts a Schlumberger Petrel exported well trajectory file into an OPM ResInsight file, containing all the wells.

All the aforementioned options and tools are described in detail in APPENDIX C:OPMRUN – FLOW JOB SCHEDULER,

Note

OPMRUN can be run as either a Linux or a Windows application. If the software is installed and run under Windows, then the program automatically handles the file naming conventions of the two operating systems. That is under Windows, the application uses the Windows file name to select the files, and then automatically converts the file name to the equivalent Linux file name to run under WSL.

2.4 IMPROVING SIMULATOR CONVERGENCE AND NUMERICAL PERFORMANCE

In general, most simulator performance issues are caused by the data used by the simulator, rather than the numerical algorithms used to solve the equations presented in sections *1.2 Black-Oil Model Equations* through *1.4 Multi-Segment Well Model*. Thus, it is important to verify all warning messages and to address the issues raised by these warnings. Naturally, some warnings can be safely ignored, while others should not. Just because the simulator runs with warning messages does not mean that the results are reasonable, or that numerical performance has not been impacted.

This section is therefore broken into two parts, the first part discusses potential data errors and how to address them, and the second section outlines the numerical controls available to improve the simulator's performance. The latter should only be done after the data quality issues have been rectified, although, it is not uncommon for users to skip the data quality step altogether, and jump to "tuning" the model's numerical controls - to be clear, skipping the data quality step is strongly not recommended.

2.4.1 DATA QUALITY AND ASSURANCE

GRID Section

Grid Configuration

In full field models grid distortions may occur due to faulting and the structural complexity of the geological model, and ideally one wishes to have all the cells to be orthogonal. Grid cells are orthogonal if all grid lines intersect at a right angles, that is at 90°. This is because orthogonal grids offer significant advantages in solving a system of partial differential equations used computational fluid dynamics. In addition, they ensure that the fluid flow is not being unduly influenced by the grid orientation effects, as cell to cell flow only occurs across connected cell faces.

Most earth modeling software can produce a histogram of the cell angles as an aide to checking the orthogonality of the grid. A common cause for cells not being orthogonal, as well as creating other grid artifacts, is the grid cells following actual the faulting traces, as oppose to using "zig-zag" fault traces that follow the grid. A typical fault trace grid is illustrated in Figure 2.18.

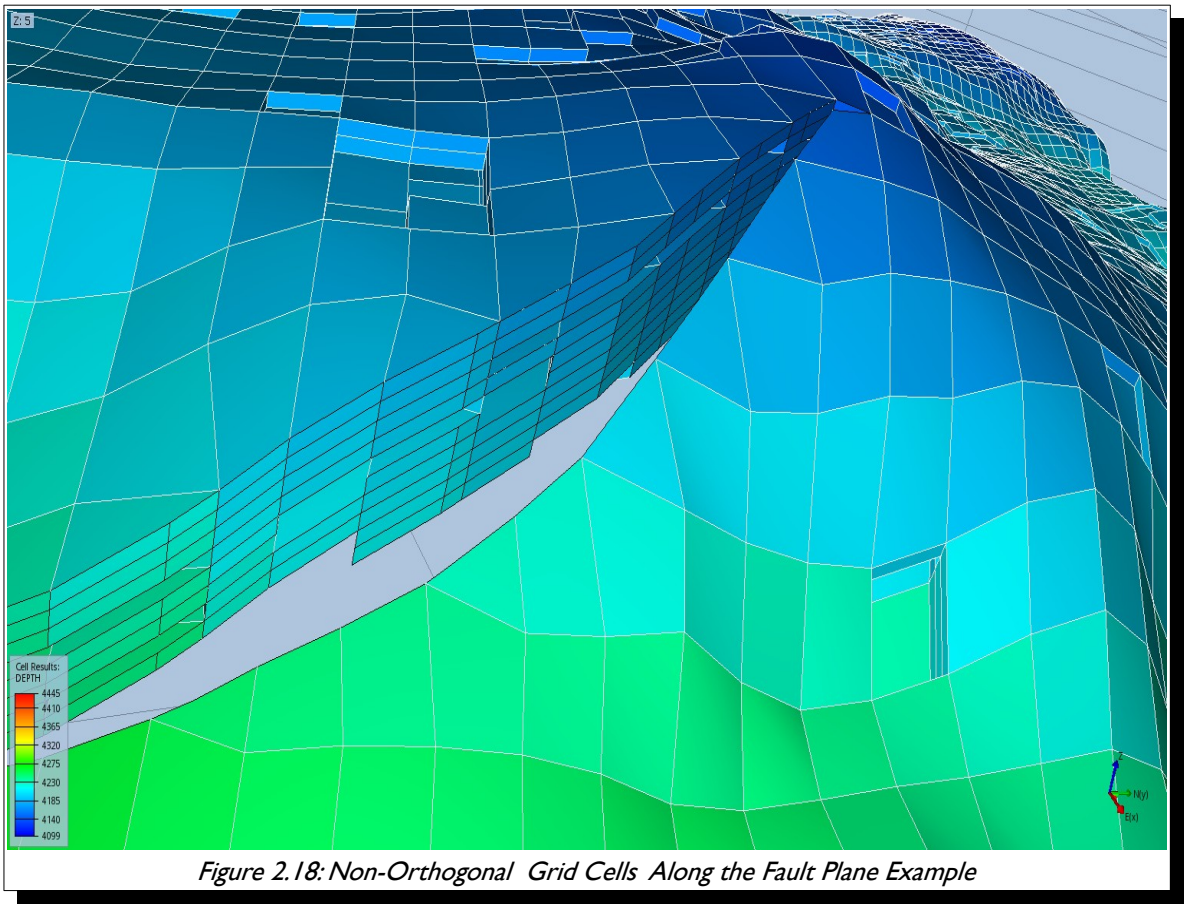

Figure 2.18: Non-Orthogonal Grid Cells Along the Fault Plane Example

Notice in Figure 2.18 how the cells along the fault plane are severely distorted, with some cells having only three faces instead of four in the x-y plane. Now compare this to the Norne model shown in Figure 2.19, which has more complex faulting, and yet the grid along the fault planes is mainly orthogonal.

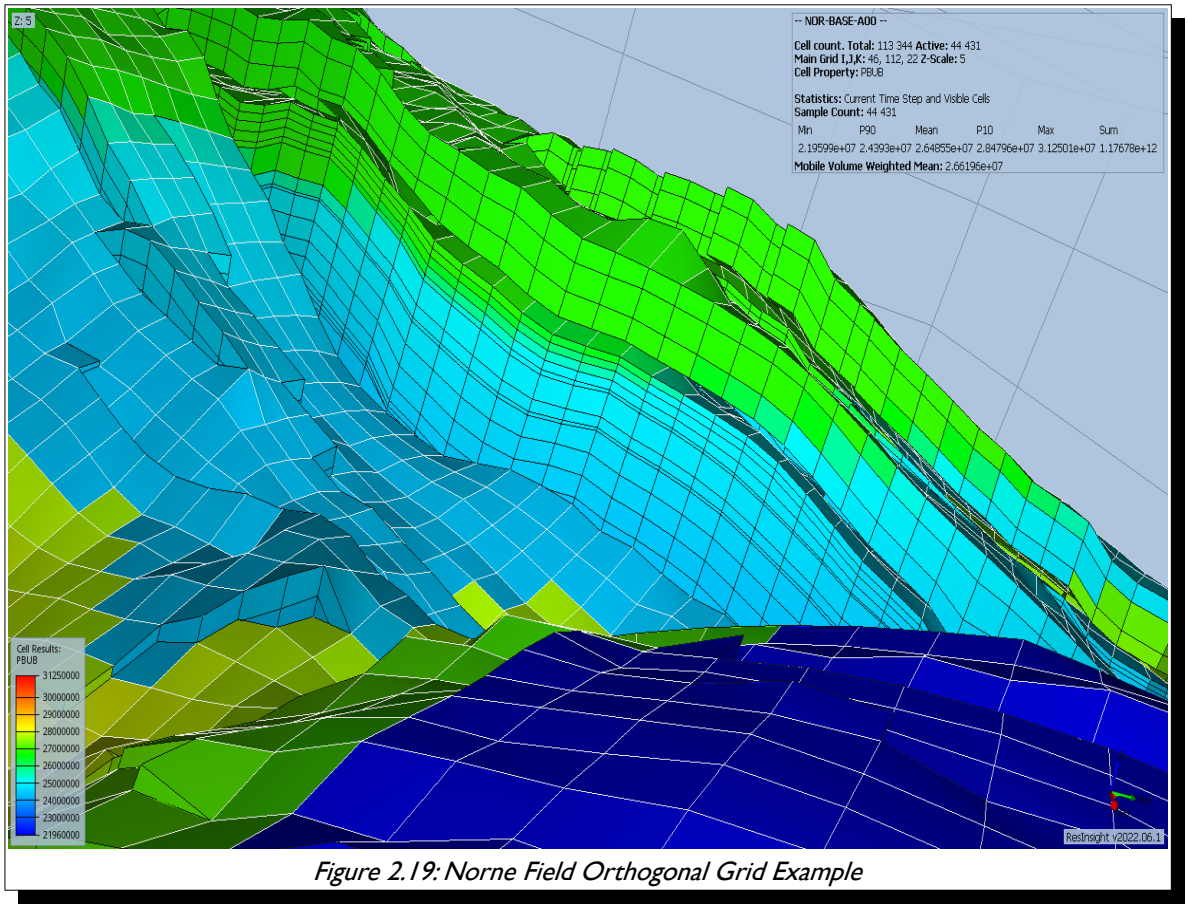

Figure 2.19: Norne Field Orthogonal Grid Example

Grid Property Data and Active Cells

There is a current trend in the industry for not applying cut-offs to the petrophysical parameters used to generate the grid property data (porosity, net-to-gross, etc.). The philosophy behind this approach is that the simulator should determine what is reservoir and is capable of contributing to flow within the reservoir, and what is non-reservoir. At first glance this would appear reasonable, but unfortunately the inclusion of low pore volume and low permeability grid cells will have a dramatic negative impact on the model's numerical convergence and run times. This is because one ends up with many more active cells than otherwise, plus the fact that low pore volumes grid blocks will be connected to high pore volume cells. Because of this inter-connectedness, a change in a large pore volume grid block will have disproportional change on a low pore volume cell, which will result in smaller time step sizes in order to satisfy the numerical controls.[46] That is, the low pore volume cell throughput will influence the simulator's selected time step size disproportionately.

Nevertheless, even if the more conventional approach to the model build is undertaken by applying some form of petrophysical cut-offs, there may well still be grid blocks containing small pore volumes. In this case the MINPV keyword in the GRID section can be used to set a minimum pore volume threshold in which cells below the threshold value will be automatically made inactive. It is not possible to give absolute guidance for a suitable pore volume value to be used with MINPV, the best approach is to run some sensitivities to investigate the impact of different pore volume thresholds on the reduction in the number of cells and the consequent change in the fluid in-place volumes. One should also be mindful not to remove thin high permeability cells that have small pore volumes due to their size, as this will effect the model's flow behavior.

Finally, if the PINCH keyword in the GRID section, is also in the input deck, then one must be cognizant of the interaction between the two keywords.

[46] *The large pore volume differences make the solution of the linear system of equations more challenging, due to the residual errors in certain grid cells or areas within the grid, that are much harder to reduce with iterative solvers. This results in more convergence failures, smaller time steps, etc. Similarly, for highly varying cell sizes.*

Grid Coarsening

As the number of active grid blocks directly effect a model's run time, reducing the number of active cells by coarsening areas of model that are of secondary importance, can be beneficial to the overall run time of a model. An example of where this approach should be considered is the modeling of aquifers. It is not necessary to fully model an aquifer, by having the model cells cover the whole area of the aquifer. Instead, incorporating either analytical aquifers via the *AQUCT – Define Carter-Tracy Analytical Aquifers* and *AQUFETP – Define Fetkovich Analytical Aquifers* keywords, or numerical aquifers using the *AQUNUM – Define Numerical Aquifer Properties* keyword, can effectively re-produce the aquifer response. Both types of aquifers have advantages and disadvantages.

Analytical aquifers have the advantage that their response and behavior can be matched by using material balance techniques to quantify the aquifer properties, by history matching the measured pressure response in the hydrocarbon zones. This is an efficient analytical modeling work flow to identify the aquifer response, the properties derived can therefore be more or less directly incorporated into the dynamic model. The dis-advantage is that analytical aquifers are not directly comparable with geological interpretations, which may, or may not, be important, depending upon the circumstances.

The opposite is true for numerical aquifers in that an approximate aquifer volume and property data can be matched with current geological interpretation, but cannot be history matched in most material balance software, as numerical aquifers in general are not supported.

Nevertheless, no mater which type of aquifer is employed, they should not be directly connected to hydrocarbon bearing cells, ideally there should be between three to five water bearing cells between the aquifer connected cells and the hydrocarbon cells. However, the water cells may vary in size, such that water cells connected to the hydrocarbon zone are of similar size, and then increase in size towards the edge of the model. The reason for this is that we wish to limit "small" hydrocarbon cells being directly coupled to "large" water cells, that will hinder the length of time steps selected by the simulator due to the convergence criteria.

Grid Isolated Cells

Simulation models should only include grid blocks that influence the flow and recovery in the model. One common issue with some of the geo-statistical formulations used to generate the grid and the associated grid property data, is the tendency to create isolated grid blocks. These isolated grid blocks are not connected to the rest of the model and therefore do not influence the behavior of the model. Figure 2.20 shows a typical example, with the cells circled in red being the isolated cells.

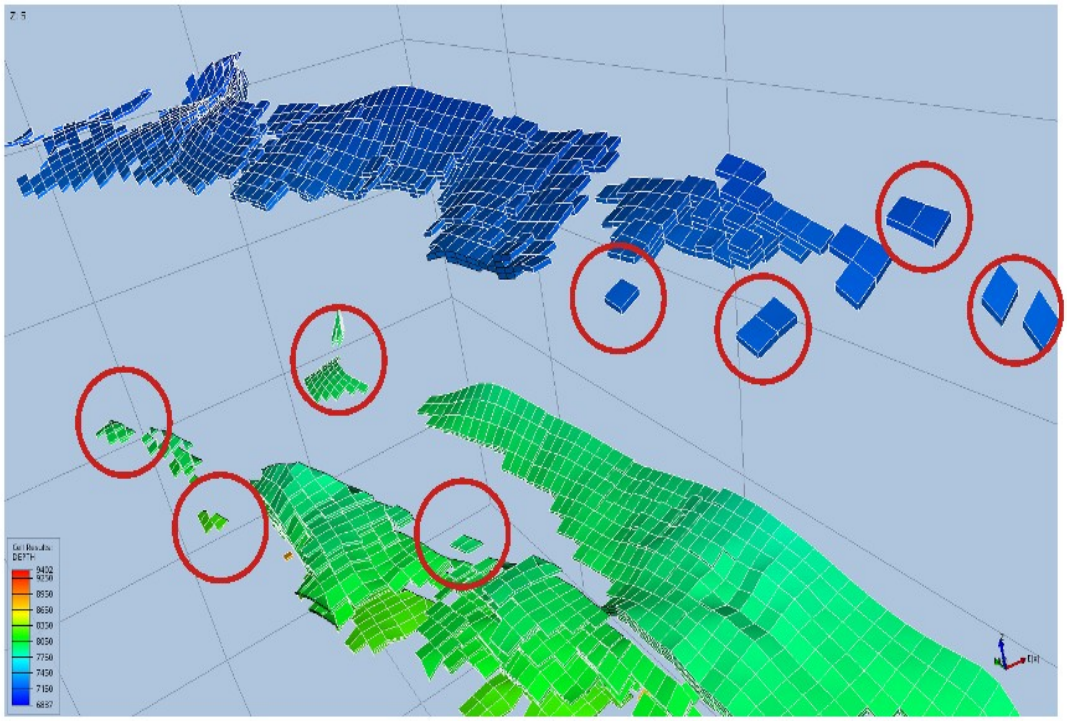

Figure 2.20: Isolated Cells Example

Unfortunately, these cells will be included in all the calculations, and may cause numerical issues due to their unchanging state, both pressure and saturation. They will also unnecessarily add to the active cell count, and therefore effect the simulation run time. In addition, they will give a false impression of the average reservoir pressure, as the isolated cell pressures will remain at initial conditions throughout the simulation run. If model convergence is proving difficult, then this may be a potential cause of the problem. In any case, it is recommended that the identified isolated cells be removed by making them inactive via the ACTNUM keyword in the GRID section.

If there are only a few isolated cells then they can manually be made inactive; however, in many cases this not possible due to the number of isolated grid blocks. In this case, it is better to revert back to the static model and fix the issue in the earth modeling software. Indeed, if there are numerous isolated grid blocks this may be indicative that an inappropriate approach has been used to generate the static model, although it may be also due to the depositional environment as well.

PROPS Section

This section describes potential issues associated with the property data and is split into two separate sub-sections:

1) The first sub-section covers the rock properties, and in particular the saturation functions (relative permeability curves), that can have a dramatic impact on reservoir performance, especially for the non-linear solver. As will be shown later, it is important that the derivatives of the relative permeability curves are smooth and monotonically increasing or decreasing depending on the phase of the relative permeability fluid. Particular care must be taken if end-point scaling is being used, as it is not uncommon for the resulting de-normalized curves being inappropriate, even though the normalized curves are reasonable and correct.

2) The second sub-section addresses issues that may arise with the fluid properties, and inconsistent PVT data that may result in the simulation struggling to converge in the linear solver.

PROPS Section: Saturation Function (Derivative)

In general, one should not enter laboratory derived relative permeability data directly into the simulator. This is because it is dubious that laboratory measurements on 1½ inch core plugs can represent the flow in 100 x 100 x 1.0 m grid cell in the model. There are various upscaling techniques that can account for the scaling issue, using various forms of relative permeability curves, including the laboratory curves, piston-like curves and thickness average curves etc. However, the resulting pseudo relative permeability curves tend to not have smooth derivatives, which will have a detrimental impact on convergence efficiency. Thus, it is common practice to use the laboratory derived curves, either in an upscaling workflow or as part of the input workflow, and to fit a Corey[48] type curve to the "rock" curves in order to smooth out any discontinuities.

Unfortunately, neither OPM Flow nor the commercial simulator, unlike some other simulators, support the direct entry of Corey type curves; however, OPM Flow does support the more advance and flexible LET family of models instead. See section *8.2.6Saturation Table Generation - LET Functions* and Lomeland et al[47] for further information on the model, as well as the *SGOFLET– Gas-Oil LET Relative Permeability Functions*, *SGWFLET – Gas-Water LET Relative Permeability Functions*, and the *SWOFLET – Water-Oil LET Relative Permeability Functions* keywords in the PROPS section.

Corey[48] combined the work of Purcell[49] and Burdine[50] that was widely accepted for its simplicity. His original equations were developed for the drainage cycle in water-wet sandstones, but have also been used in carbonate formations. Corey's original water-oil equations were as follows:

$$k_{ro}\left(S_w\right) = \left[\frac{1 - S_w}{1 - S_{wcr}}\right]^{n_o} \tag{2.1}$$

$$k_{rw}\left(S_w\right) = \left[\frac{S_w - S_{wcr}}{1 - S_{wcr}}\right]^{n_w} \tag{2.2}$$

Where:

$k_{ro}(S_w)$	= relative permeability to oil,
$k_{rw}(S_w)$	= relative permeability to water,
n_o	= Corey oil exponent, set to four in the original paper,
n_w	= Corey water exponent, set to four in the original paper,

[47] *Lomeland F., Ebeltoft E. and Thomas W.H., 2005. A New Versatile Relative Permeability Correlation. Paper SCA2005-32 presented at the International Symposium of the Society of Core Analysts held in Toronto, Canada, 21-25 August, 2005.*

[48] *Corey, A. T.: "The Interrelation Between gas and Oil Relative Permeabilities", Production Mon., 19. 38. (1954).*

[49] *Purcell, W. R., "Capillary Pressures- Their Measurement Using Mercury and the Calculation of Permeability Therefrom", Transactions AIME, 186, 39 (1949).*

[50] *Burdine, N. T., "Relative Permeability Calculations from Pore Size Distribution Data", , Transactions AIME, 198, 71 (1953).*

S_w = water saturation, and
S_{wc} = critical water saturation.

The denominator in equations (2.1) and (2.2) scales the water saturation to the mobile water phase. There are several forms of these equations, with the most common normalizing the saturation over the mobile hydrocarbon phase, as depicted in equations (2.3) and (2.4).

$$k_{ro}(S_w) = k_{row}\left[\frac{1 - S_w - S_{orw}}{1 - S_{orw} - S_{wcr}}\right]^{n_o} \quad (2.3)$$

$$k_{rw}(S_w) = k_{rww}\left[\frac{S_w - S_{wc}}{1 - S_{orw} - S_{wcr}}\right]^{n_w} \quad (2.4)$$

Where,

k_{row} = maximum oil relative permeability at Swc,
k_{rw} = maximum water relative permeability st Sorw,
S_{wc} = critical water saturation, and
S_{orw} = residual oil saturation under a water flood (SOWCR).

Figure 2.21 show a typical Corey plot, with the plot at the top of the figure showing the Corey plot and the bottom plot showing the derivative plot, the data is also tabulated in Table 2.2. Notice in Figure 2.21 that the water curve does not extend to 100% water saturation, this is an error as the water below the oil-water contact would have restrictive water flow.

Table 2.2: Oil-Water Saturation Function and Derivative Table

If we correct the data shown in Figure 2.21 by extending the water curve to KRW, then we obtain the result shown in Figure 2.22, but notice what has happens to the water derivative plot, which now has a discontinuity because of the extension. Thus, small changes to the relative permeability curves can gave an undue influence on the simulator's performance. In this particular case, the effect is minor as it is only one point that has of issue, but it is not uncommon to have multiple discontinuities in numerous curves that will have an impact on convergence.

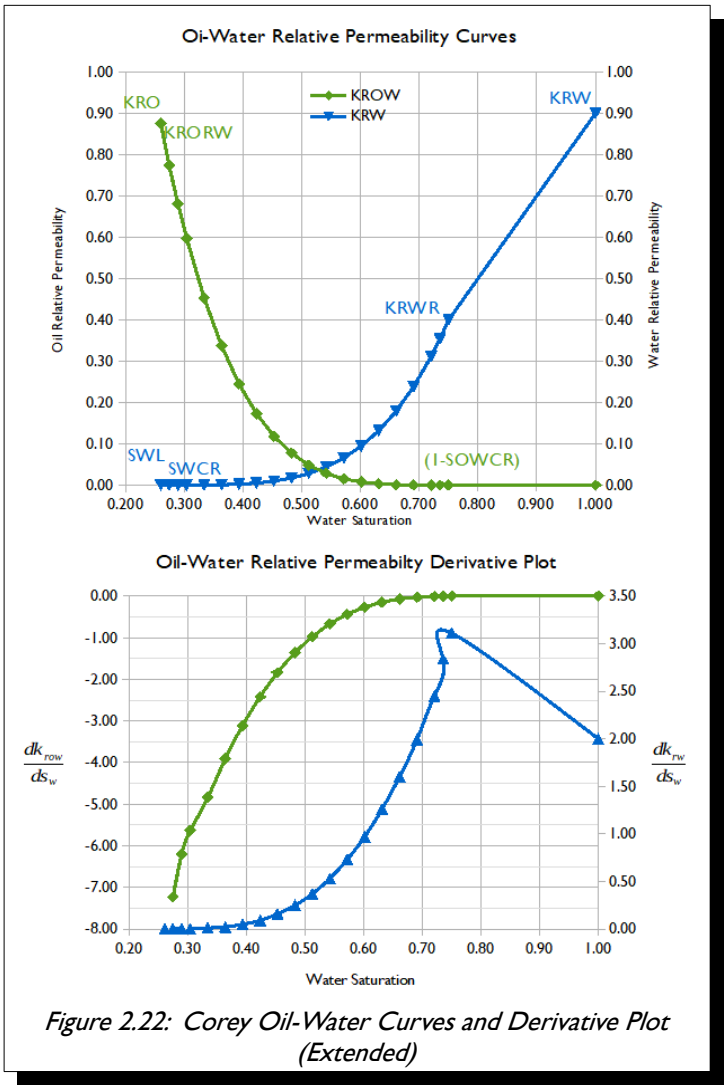

Figure 2.22: Corey Oil-Water Curves and Derivative Plot (Extended)

To summarize, if convergence is an issue verify that both the entered relative permeability data and capillary pressure do not have numerous discontinuities in the derivative plots.

The next section discusses the impact and relationship lowest saturation and critical saturation, in terms of pressure depletion. However, again, care should be taken to avoid any potential discontinuities in the derivatives between these to data points.

PROPS Section: Saturation Function (Lowest Saturation and Critical Saturation)

In most cases time step chops caused by saturation changes, may be reduced by avoiding having the lowest and critical saturations being the same. For example for the water phase, this would mean having different values for SWL and SWCR. The reason for this due to the compressibility difference between the gas and liquids (oil and water), as illustrated Figure 2.23. Here we assume that initially 80% of cell's volume of 100 m3 is occupied by gas and the remaining 20% by water.

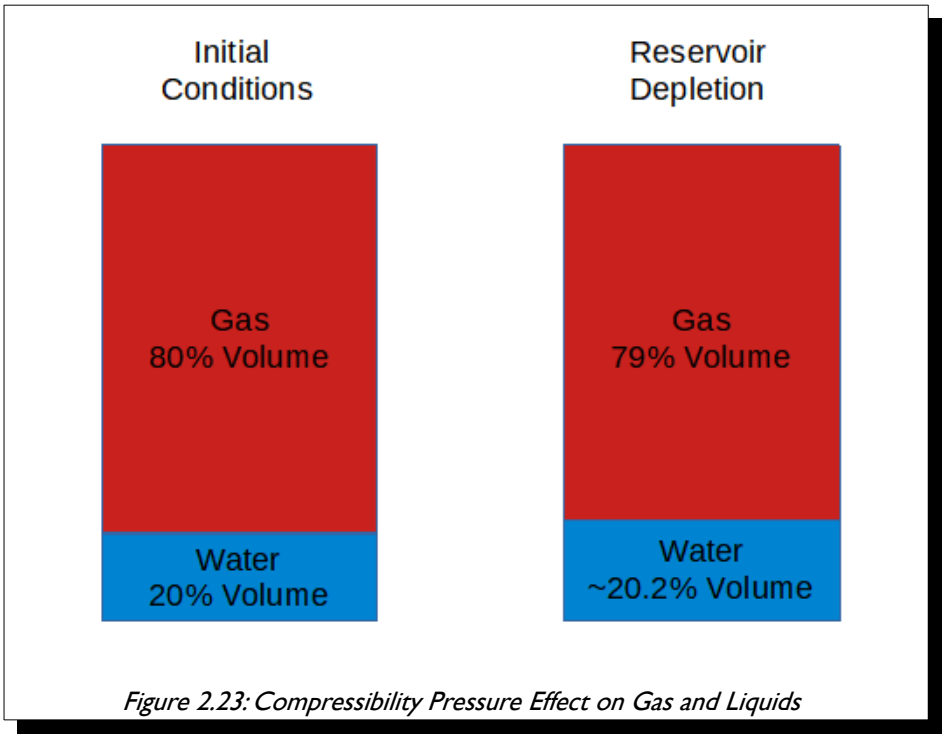

Figure 2.23: Compressibility Pressure Effect on Gas and Liquids

Assuming there is no flow in or out of the grid block and the cell pressure decreases due to production elsewhere in the model, that results in a small reduction (1.0%) in the cell's pore volume. And since gas is much more compressible than oil and water, then the gas volume will decrease by approximately1.0%; whereas the water will increase slightly to 20.2%[51]. Thus, if SWL was set to 20%, then the 0.2% increase in water saturation would become mobile and start to flow to the other connect grid blocks. This can be a cause of instability.

The solution of cause is to enter values for SWL and SWCR, such that there is a small difference between them, around 2% to 5% for example, instead of this:

```

The incorporation of the of Sw equal to 0.31should assist convergence and will not influence the oil in-place, although it will slightly reduce the water mobility between the water saturations of 0.30 and 0.31. Secondly, as one can see from Table 2.3 the additional water saturation value did not cause any derivative discontinuities.

Oil-Water **Saturation Function** and Derivative **Table**						
Sw	**Krw**	**Krow**	**Pcow (psia)**	$\frac{dk_{rw}}{dS_w}$	$\frac{dk_{row}}{dS_w}$	$\frac{dP_{cow}}{dS_w}$

Table 2.3: Oil-Water Saturation Function and Derivative Table (Modified)

Note also that same approach can also be applied to the oil phase.

PROPS Section: Saturation Table End-point Scaling

The end-point scaling functionality in OPM Flow gives tremendous flexibility, allowing one to use a limited set of relative permeability functions by accounting for rock property variation, such that each cell in the model has its own relative permeability function. However, both the original normalized functions and the de-normalized grid cells functions should be check for consistency. In general, it is best to avoid entering the original curves as normalized curves, in the classical sense, but instead enter a standard curve or a more correct normalized curve that takes into all the end-points. The reason for is shown in Figure 2.24 and Figure 2.25.

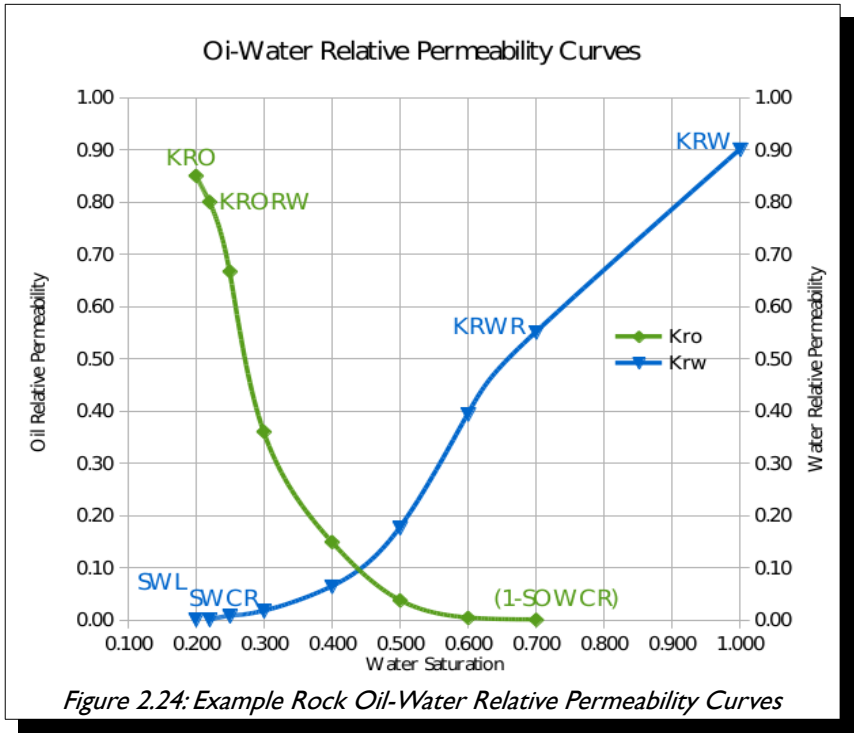

Figure 2.24: Example Rock Oil-Water Relative Permeability Curves

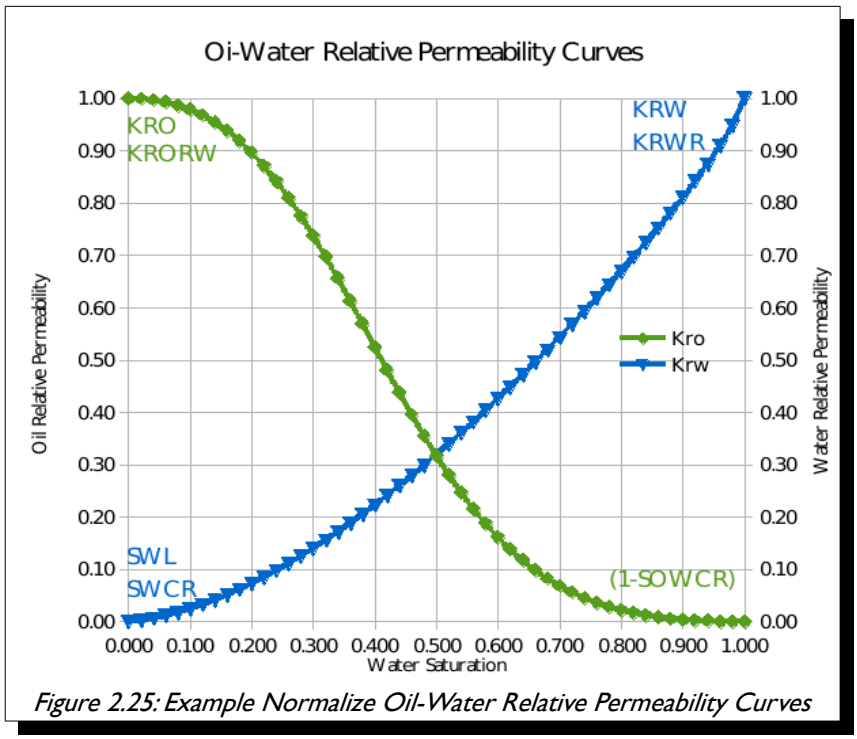

Figure 2.25: Example Normalize Oil-Water Relative Permeability Curves

Notice how the distinction between KRO and KROW is no longer present in the normalized curve in Figure 2.25, and similarly for KRW and KRWR, and SWL and SWCR. Thus, the simulator will ignore one of each pair of end-points - this can lead to unexpected results for the grid cell based saturation functions. An example is shown in Figure 2.26 for a gas-water saturation table. Notice how the de-normalized end-point water relative permeability, KRW, is only 0.20 versus 1.00 for the normalized value of KRW.

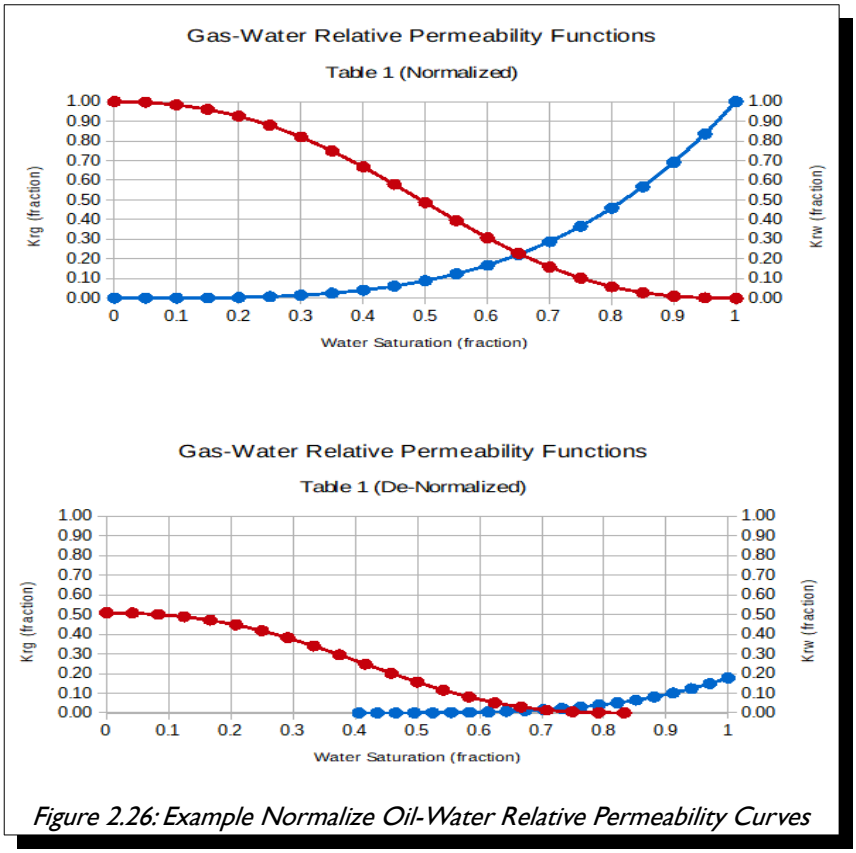

Figure 2.26: Example Normalize Oil-Water Relative Permeability Curves

Consequently, water influx will be inhibited leading to unreliable results in terms of water production, and potentially gas production if aquifers are present in the model.

As mentioned previously, entering a correct original curve that is not normalized will automatically resolve these type of issues. If a normalized curve is entered, then ensure that simulator can distinguish between SWL and SWCR etc., based on the variable definitions provided in Error: Reference source not found, Error: Reference source not found, and Error: Reference source not found.

Finally, see the SCALCERS keyword in the PROPS section, that defines the options used in the re-scaling process, including the options for two point and three point scaling. Whatever option is selected, always verify that the de-normalized curves that will be used in the model are correct and reasonable.

PROPS Section: Fluid Properties

It is important that the fluid properties are consistent to avoid convergence issues, and thus the simulator performs a series of validation checks to ensure that data is consistent. The following example indicates the oil formation volume factor is is not monotonically increasing for increasing GOR.

```

The data is displayed above and the offending entries are shown in bold. These type of PVT warning messages are important and should be addressed before continuing with the simulation run.

SOLUTION Section: Initialization

The first quality control check that should be performed once the model has been initialized, is to check that the pressure distribution matches the observed data, this specifically important when there are multiple stack reservoirs in different hydraulic pressures zones, as per the likes of the oil and gas fields in the Malay Basin and the deep water fields in Indonesia and the Gulf of Mexico. One effective way to do this is to plot the initial pressure data versus depth from exploration wells, and compared this to the equivalent model pressures at the same depth, as shown in Figure 2.27. Here the measured data is from the RFT[52] ("Repeat Formation Tester") tool that measures the observed pressure profile in the open-hole well bore.

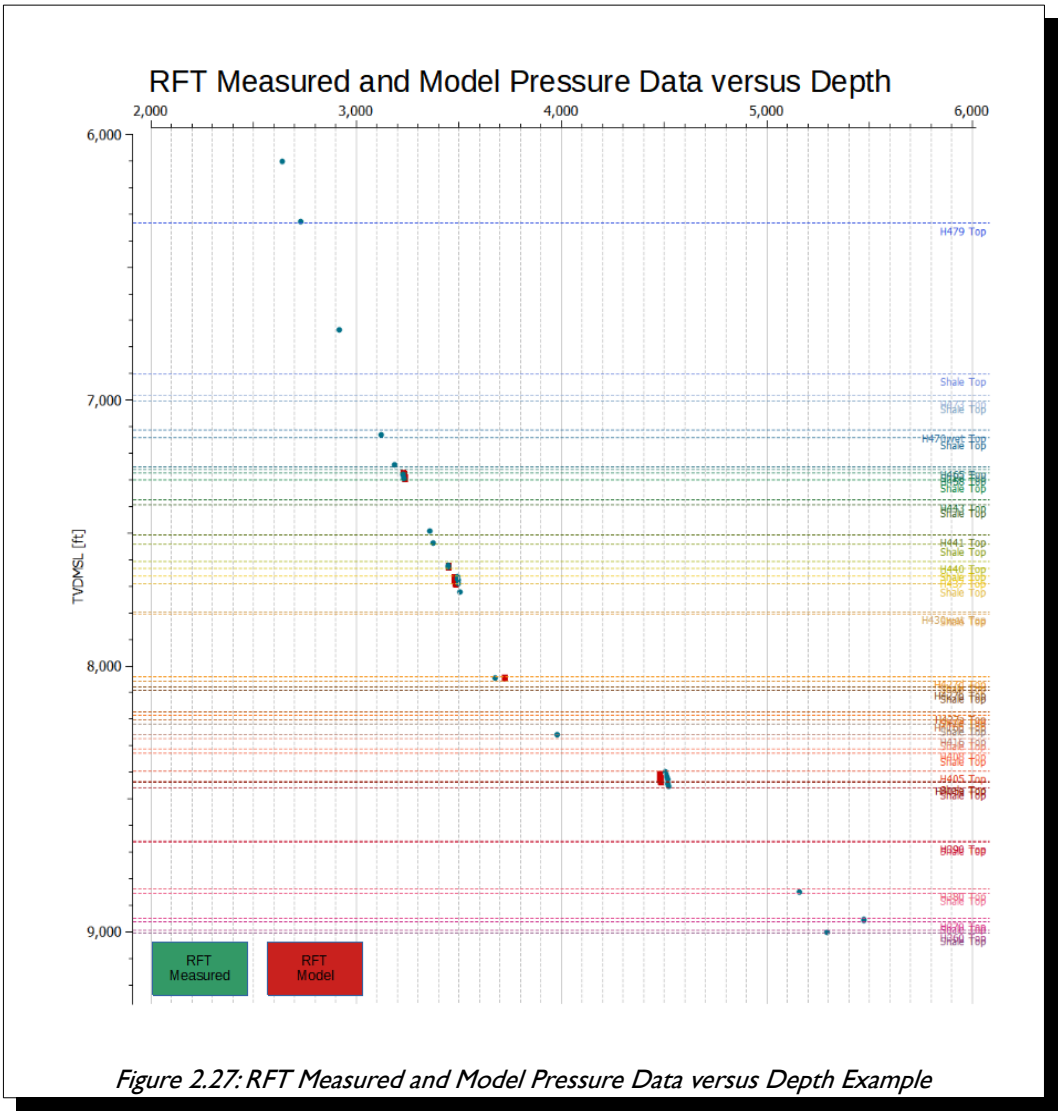

Figure 2.27: RFT Measured and Model Pressure Data versus Depth Example

Figure 2.27 was created in OPM ResInsight, and shows good agreement between the two data sets. This type of plot is commonly constructed when history matching field performance, but is also useful in verifying the initial pressure distribution. Note that for simple models with only a few reservoir zones, then this plot can be replaced by simply checking the three dimensional pressure distribution.

[52] *Repeat Formation Tester (RFT) tool is an open hole device which is an updated version of the Formation Interval Tester (FIT), both of which are run on wire line. Both tools take multiple pressure readings (at various depths) thus enabling a pressure depth profile to be obtained from the formation, and, in addition, they can also take fluid samples from the formation. The latest tool available is the Modular Formation Dynamics Tester (MDT), which, as its name suggests, is a modular tool that can be assembled in different configurations depending on what are the objectives for running the tool. Thus, the term RFT measurements applies to all tools that measure a pressure profiles versus depth (RFT/FIT/MDT etc.).*

If the SWATINIT keyword in the PROPS section is used to initialize the model by setting each grid block's initial water saturation ("Sw"), then OPM Flow will re-scale the water-oil capillary pressure curves entered via the SWFN saturation functions in the PROPS section, so that the resulting initialized Sw matches the values in the SWATINIT array.

Normally the SWATINIT array is generated in the static earth model when calculating the hydrocarbons in-place volumes using a Saturation Height Functions ("SHF") derived from capillary pressure functions. Static earth models do not directly use capillary pressure in these type of calculations as individual cell pressures are not available. There is therefore some potential for inconsistencies to arise between the two sets of formulations. This is normally manifested by extreme scaling in the scaled capillary pressure values calculated by the simulator. These scaled large values of capillary pressures can result in numerical issues, and should be addressed, by verifying that the SHF used in the earth model to derive the SWATINIT array and the unscaled capillary pressure values on the SWFN keyword are consistent. Note in general, the scaled capillary pressure values calculated by the simulator, should be roughly in the same range as the entered unscaled data, as shown in Figure 2.28 for the Norne field.

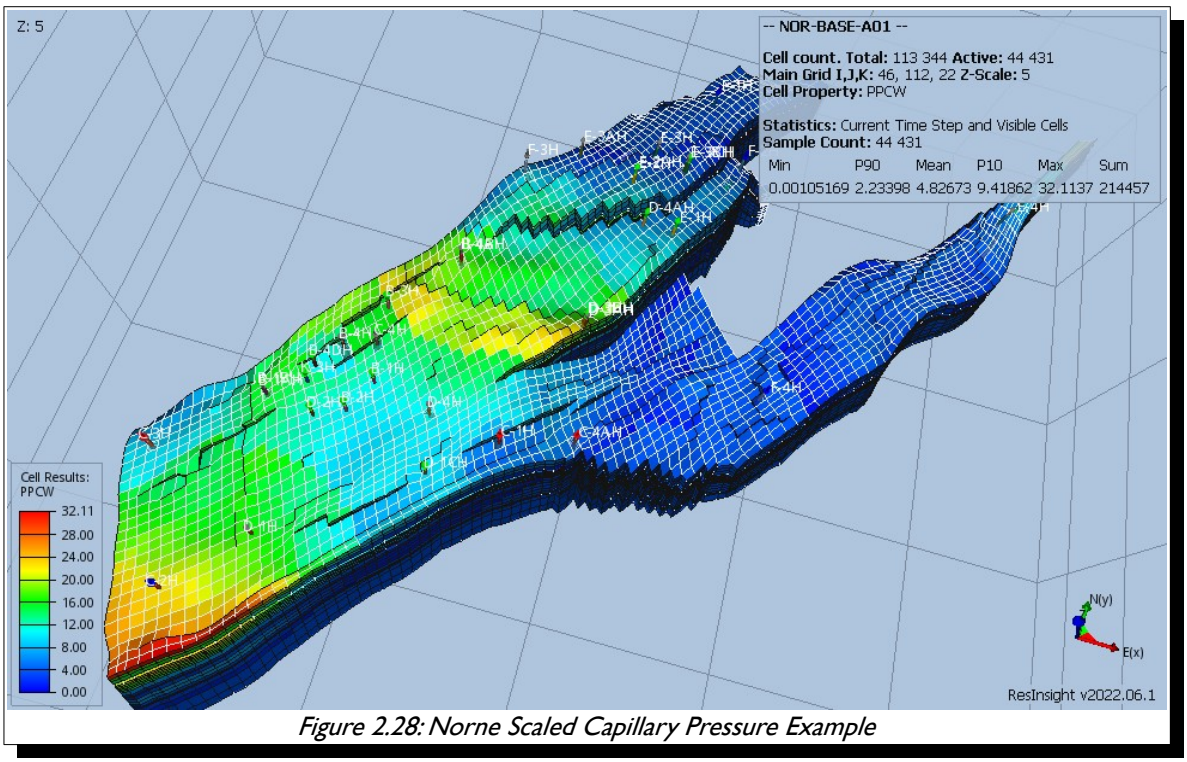

Figure 2.28: Norne Scaled Capillary Pressure Example

Note that although the PPCWMAX keyword can be used to set a maximum scaled capillary pressure value, a more technically sound approach is to resolve these inconsistencies before continuing with the model build.

Once a model is built and can be initialized, it is good practice to run the model with no production for several years to ensure that the initialization is stable. There should be under these circumstances no, or very limited fluid movement, and the pressure should remain stable, that is constant, although a small drift may be observable. An example for the Norne model is shown in Figure 2.29 on the field level, although it can, and should be performed on a region by region basis if the model is not stable.

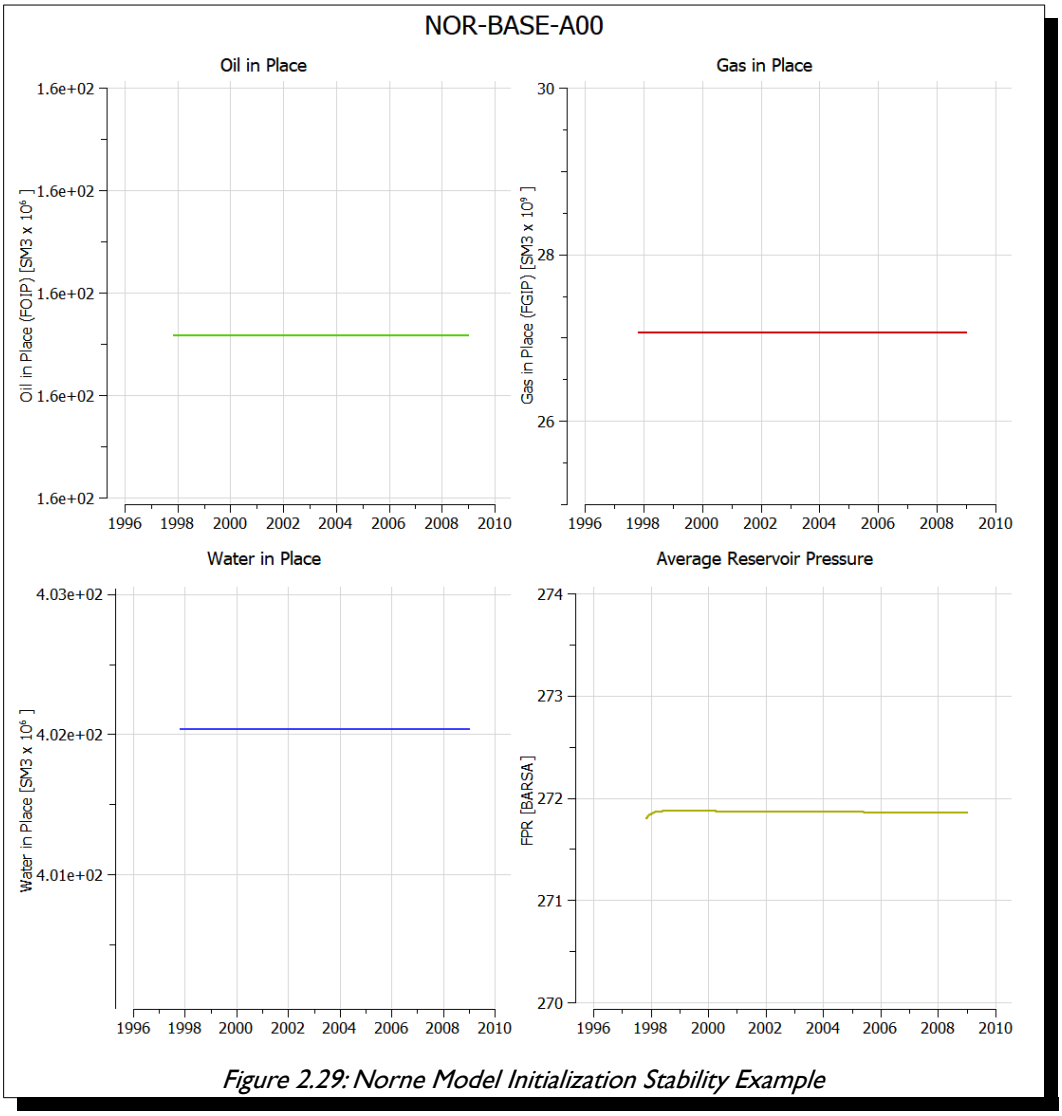

Figure 2.29: Norne Model Initialization Stability Example

Potential causes for the instability are:

1) Aquifer Not in Equilibrium with the Connected Hydrocarbon Zones. One can check for this by switching off all the aquifer connections and see if the instability is still present. If this corrects the issue then verify the aquifer connections by reviewing the AQUIFERA array in the *.INIT file in OPM ResInsight. OPM Flow writes out the AQUIFERA value to $2^{(AQUID-1)}$ for cells connected to aquifer AQUID. If a cell is connected to multiple analytical aquifers then AQUIFERA is summed for all aquifers connected to a cell. Note that connecting cells to multiple aquifers should be avoided.

   Note aquifers should only be connected to grid blocks containing 100% water, or at the very least any hydrocarbons in the connected cells should be immobile.

2) Different PVT Regions in Communication. Recall that fluid proprieties are associated with a grid cell, so if two different PVT regions are in communication, then a m^3 of fluid from PVT region one flowing into PVT region two, will automatically assume the properties of PVT region two. This creates a material balance error that will result in numerical difficulties. One may be able to identified this by reviewing the inter-region flows to identify the source of the problem, either via the *.PRT file or the summary file out. It typically occurs across fault planes, when one PVT region butts against a different PVT region along the fault face.

   There are several solutions to this, firstly, one can set the transmissibility along the fault plane to zero using the MULTFLT keyword in the GRID or EDIT sections.

   Secondly, create a MULTNUM array based on the PVTNUM array, as the PVTNUM keyword is not available in the GRID and EDIT sections. Then use the MULTREGT keyword with MULTNUM array in the GRID or EDIT sections to set the transmissibility between the offending regions to zero.

   Finally, one can use the THPRES keyword in the SOLUTION section combined with the EQLNUM array to isolate the offending regions. Normally, but not always, the PVTNUM and EQLNUM arrays are identical, if not, then it is relatively easy to copy the aforementioned MULTNUM array to the EQLNUM array, then add the additional equilibration data to the EQUIL keyword. One advantage of this option is that it will cater for the scenario for when the PVT regions are initially isolated, but after a certain production period, the faults break down and there is communication between the two regions. In this scenario, one still has the material balance error as different fluids inter-mix. If this is the case then the API Tracking option should be used to account for this behavior. See the API keyword in the RUNSPEC on how to activate this option.

3) Different Equilibration Regions in Communication. This is similar to (2) above and the remedies are also similar, so the solution is not repeated here.

4) PVT Data Not Consistent with Equilibration Data. In an oil-gas system the saturation pressure, that is the bubble-point pressure should be the pressure at the GOC, and similarly for the dew point. Conveniently, OPM ResInsight can produce such plot, as depicted in Figure 2.30. The figure illustrates that gas gradient (shown in red), and the oil gradient (shown in green) from the PVT data intersect at the GOC, which matches the initial pressure profile (shown in blue) from the grid cells. Thus, confirming the consistency of the two data sets.

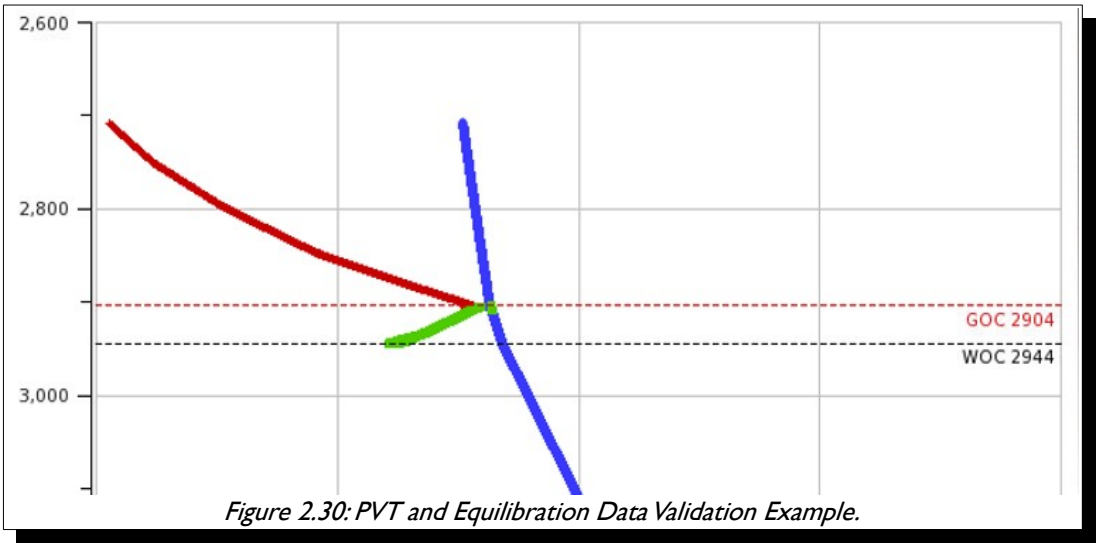

Figure 2.30: PVT and Equilibration Data Validation Example.

SCHEDULE Section

A common issue in most simulation models that employ Vertical Lift Performance ("VLP") tables used to relate a well's Tubing Head Pressure ("THP") to its Bottom-Hole Pressure ("BHP"), is the consistency of the data. Note that this is not just limited to wells, but also the network pipelines as well, that describe the pressure drop between the inlet node and the outlet node.

```
Warning: VFPPROD table 39 has 5 non-monotonic points of BHP(THP)
In /media/OPM/Fields/Norne/Model/INCLUDE/VFP/B3H.Ecl line 68
This may cause convergence issues due to switching between BHP and THP control.
```

Generally, the cause of this warning is because the VFP tables have been generated with too much fidelity or resolution. Users often consider that having more detailed and higher resolution VFP tables will give more accurate results. This is not always the case and in this particular example, will very well end up causing the wells using this particular VFP table oscillating between control modes. Figure 2.31 shows the VFP header section of the offending table, that declares the values used to generate the table.

```

Figure 2.31: VFP Table Header Example

At first glance this looks reasonable, but the problem is that the variables (LIQ, THP, WCT and GOR) are at a too high resolution, which causes some of the resulting curves to cross, due to the numerical accuracy when generating the curves. In addition, note that the maximum water cut is defined as 100%, which is unlikely to occur in practice, perhaps 98% would be more appropriate as the maximum value. OPM ResInsight is able to load VFPPROD and VFPINJ tables and to plot the data Here, Figure 2.32 shows a plot of

BHP versus THP with the various water cut values represented by the individual curves. The figure clearly illustrates the crossing of the water cut line of 80% over the 70% water cut curve, as well as the issue with the 100% water cut curve.

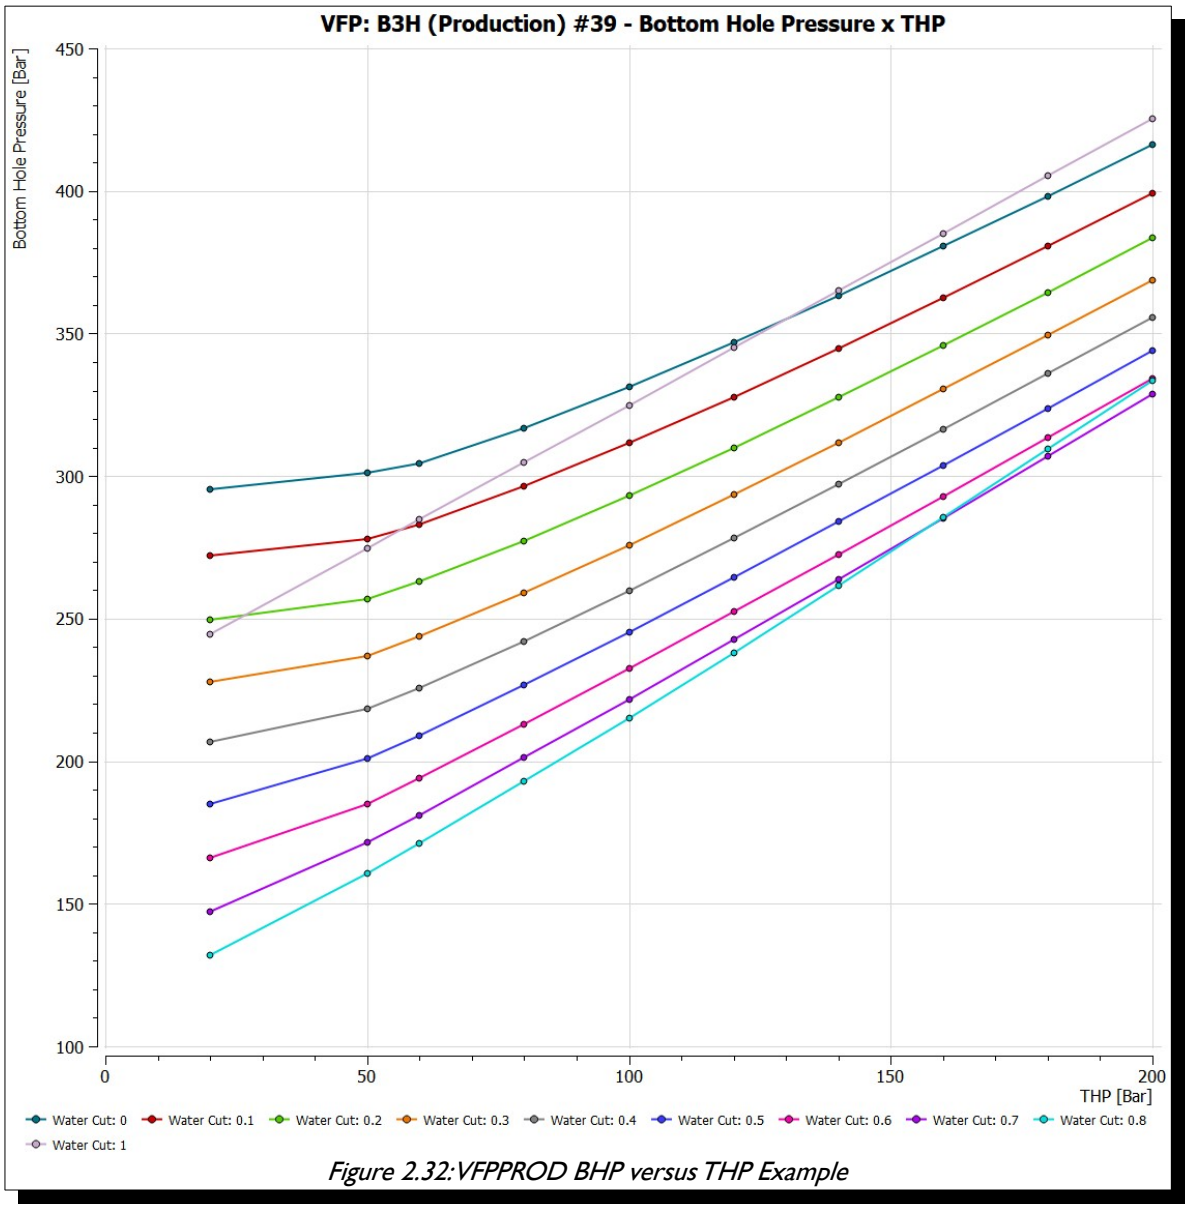

Figure 2.32: VFPPROD BHP versus THP Example

The solution is to re-generate the offending VFP tables using a coarser set of variable values. Petroleum Experts' PROSPER[53] program, as well as other nodal software programs, used to generate VFP tables for simulators, have options to generate the parameters based on the number of entries, and the minimum and maximum values for a variable, combined with various interval spacing options. Keeping the same range and selecting four or five entries and using the geometric spacing option normally resolves this type of issue. The simulator will then interpolate the coarser curves and avoid any issues with crossing curves. Note it is important to ensure that the variable ranges cover the full range of values expected to occur during the simulation, as extrapolation, unlike interpolation of the curves, is more prone to be problematic.

[53] *IPM Prosper Version 16.5 User Manual - November 2020, Petroleum Experts, Edinburgh, Scotland (www.petex.com).*

Note that this warning message can be safely ignored:

```
Warning: LIQ preferred phase not supported for well OP-01, using OIL instead
```

as it refers to the reference phase in a well's productivity index calculation. This is because OPM Flow only currently supports OIL, GAS and WATER well type fluids, as defined by the WELSPEC(TYPE) parameter in the SCHEDULE section, e.g., liquid (LIQ) is not supported. For producing, wells this mostly matters if one plots the WPI summary vector (productivity index for well's preferred phase). In the current treatment WPI will not have contributions from the water phase if the declared preferred phase is LIQ. Thus, if history matching a well's actual productivity index, this should be done on one of the recognized fluid well types. For injecting wells WELSPECS's preferred phase does not matter, since the preferred phase is (typically) reset to the injected phase via the WCONINJE and WCONINJH keywords.

2.4.2 CONVERGENCE AND NUMERICAL PERFORMANCE

Given that all the potential issues with the input data have been successfully resolved, there may still be problems with convergence and numerical performance, due to the nature of the problem the simulator is trying to solve. In Figure 2.33, at first glance, the non-linear iterations would appear to be reasonable, ranging from one to four, combined with linear iterations averaging around ten per time step. However, the time steps are very small resulting in nearly 12,500 Newton iterations and over 60,000 linear iterations in the commercial simulator, for this relatively simple problem. In fact, at the time of the study[54], the commercial simulator was unable to complete this simulation. Re-running the model with the latest version of the commercial simulator (Figure 2.33), still gives incorrect results compared to the published data.

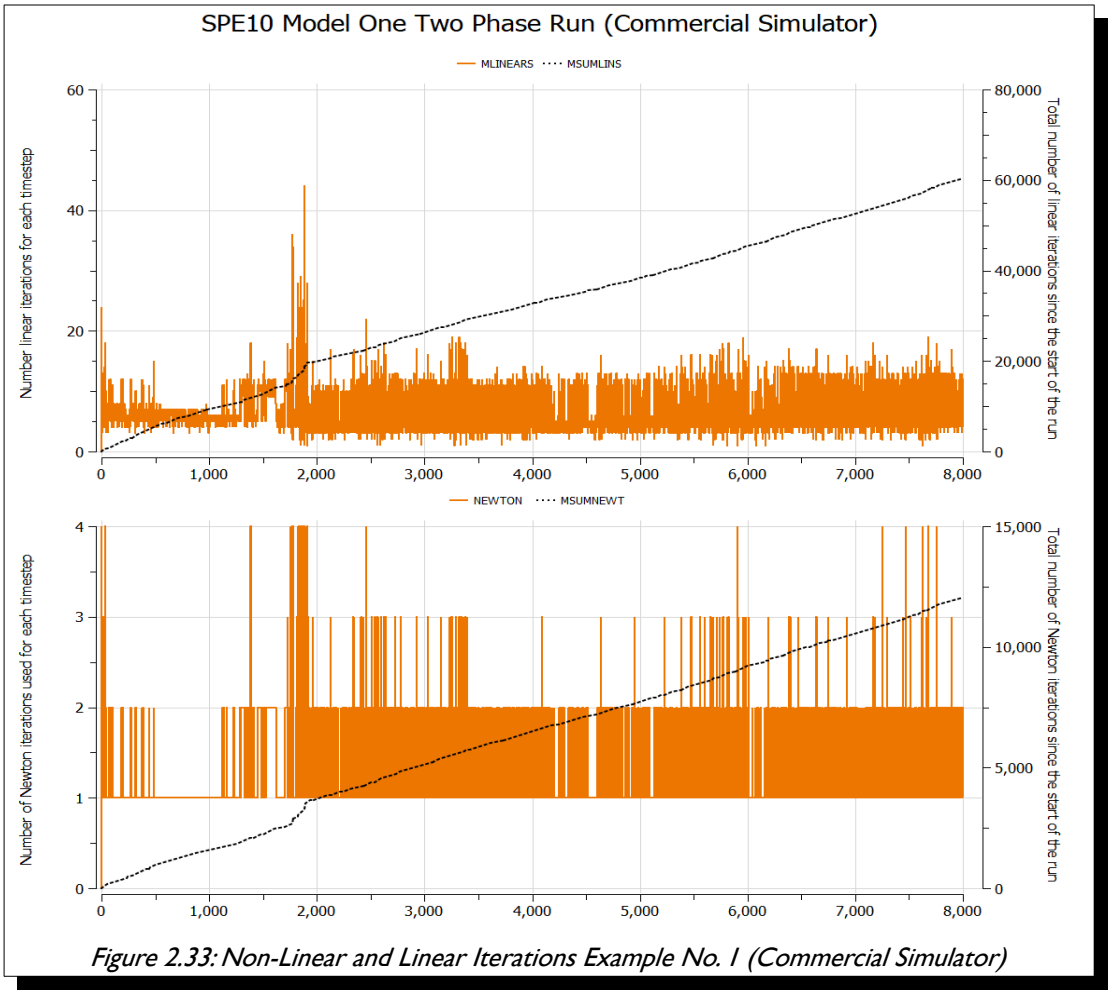

Figure 2.33: Non-Linear and Linear Iterations Example No. 1 (Commercial Simulator)

Fortunately, there are several ways to remedy poor performance, including:

1) The simplest and common approach is to manually restrict the time step size to reduce the number of time steps chops. Time step chops occurs when the simulator fails to converge at a given time step (t_{n+1}), and therefore restarts at the last successful time step (t_n) and advancing to the next time step using a smaller time step size (Δt_{n+1}) than before (Δt_n.). This was the approach used for the example in Figure 2.33, which although the model now runs, the results are incorrect.
2) Alternatively, one can change the numerical controls for the Newton-Raphson ('Newton" or non-linear solver) iteration, by changing the minimum and/or maximum number of Newton iterations. Although in general this may resolve some time step chops it can also result in a significant increase in run times, and should therefore be used with caution.

[54] *Christie, M.A., and M.J. Blunt. "Tenth SPE Comparative Solution Project:A Comparison of Upscaling Techniques." SPE Res Eval & Eng 4 (2001): 308–317. doi: https://doi.org/10.2118/72469-PA.*

3) The last option is to change the numerical parameters for the linear solver, which is generally preferable to modifying the Newton iteration parameters. OPM Flow contains various options in terms of the type of linear solver and the linear solver preconditioner to be employed, in addition to various standard linear solver parameters employed by the commercial simulator (minimum, maximum number of iterations etc.).

For example, Figure 2.34 illustrates the impact of selecting the more appropriate numerical controls. Here, the number of Newton iterations are greatly reduced to around 2,500 at the expense of increasing the number of linear iterations from ~60,000 to over 100,000. More importantly, the simulator results are correct, in that they are close to the published oil, gas and pressure values54.

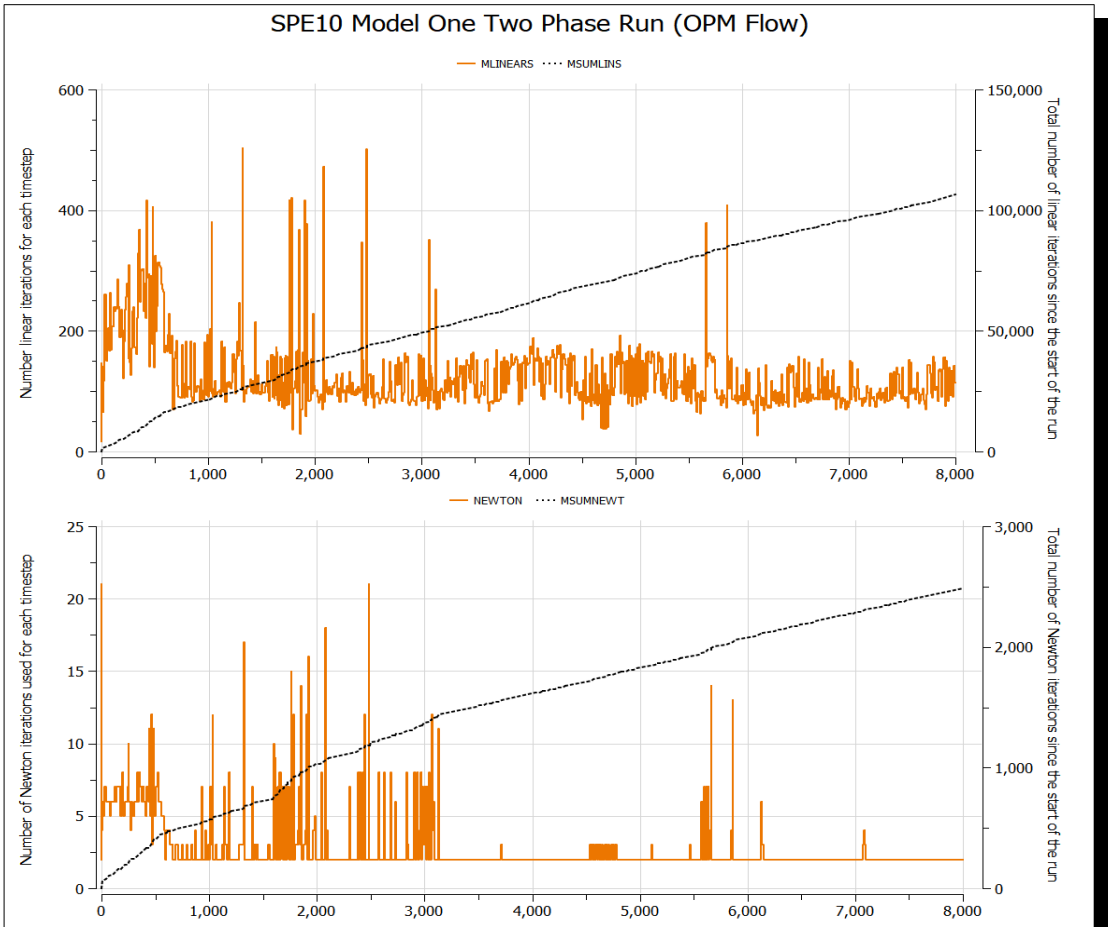

Figure 2.34: Non-Linear and Linear Iterations Example No. 2 (OPM Flow)

Note that the simulator has various other numerical performance parameters than can use used to identify the cause for under performance.

Note

To obtain the numerical performance data, the easiest way is to add the PERFORMA keyword in the SUMMARY section, that enables the writing out of a series of performance keywords to the summary file, which can then be plotted in OPM ResInsight as per Figure 2.33 and Figure 2.34.

In addition to the aforementioned PERFORMA keyword in the SUMMARY section, which is available for both OPM Flow and the commercial simulator, OPM Flow has two additional numerical performance reports that may help in identifying numerical issues. Both of these OPM Flow specific reports tabulate the numerical performance data available in the print file, in an easily readable format.

The first is the INFOSTEP report illustrated in Figure 2.35, which summarizes the numerical performance for the each time step. The Assembly, LSetup, LSolve, Update and Output header columns represent the time in seconds taken to complete the particular work item.

Time(day)	TStep(day)	Assembly	LSetup	LSolve	Update	Output	WellIt	Lins	NewtIt	LinIt	Conv

Figure 2.35: INFOSTEP Report Example

Here, the Assembly column represents the time taken to assemble the equations, *LSetup* is the time taken to setup the linear solver equations, *LSolve* is the linear solver time, *Update* is the time taken in updating the results, and *Output* is the time used for writing out the results, that is the output to the print, debug, summary, and restart files.

The *WellIt*, *Lins*, *NewtIt*, and *LinIt* column headers represent the number of iterations used to complete the time step for a given work item. Thus for time step one, the number of well iterations was zero (*WellIt*), the number of times the linear equations were setup was three (*Lins*), the number of Newton iterations used to complete the time step was two *(NewIt*), and the total number of linear iterations to completed the time step was seven (*LinIt*). The last column, *Conv*, indicates if the time step had successfully converged given the current convergence criteria, with a one indicating success and a zero indicating a failure.

By default the report is not generated to maintain compatibility with commercial simulator. To generate the report one can use the --output-extra-convergence-info command line parameter, for instance:

```
flow --output-extra-convergence-info="steps" CASENAME
```

will write the report to the CASENAME.INFOSTEP file in the same directory as the other output files.

The second report, INFOITER, contains more detailed information by reporting the numerical performance per iteration, as can be seen in Figure 2.36.

Figure 2.36: INFOITER Report Example

Here, the *Iteration* column contains the number of times the linear equations were setup, same as the Lins column in the INFOSTEO report. Note, subtracting one from the values in the *Iteration* column, gives the number of Newton iterations. Columns containing *MB* indicate a phase's normalized material balance error, and columns containing *CNV* show a phase's normalized residual error. The last column, *WellStatus*, indicates if the iteration converged or failed. Thus, report step 82 converged in seven Newton iterations with all solutions converging; whereas, report step 101 took ten iterations with two failures.

Like the INFOSTEP report, the INFOITER report by default is not generated in order to maintain compatibility with commercial simulator. To generate the report one can use the --output-extra-convergence-info command line parameter, for instance:

```
flow --output-extra-convergence-info="iterations" CASENAME
```

will write the report to the CASENAME.INFOITER file in the same directory as the other output files. Finally to generate both reports use the following command line option.

```
flow --output-extra-convergence-info="stepsiterations" CASENAME
```

The following sections now attempt to give some guidance on how use the numerical controls to resolve the simulator's performance, assuming that all the issues with the input data have been successfully resolved.

2.4.3 TIME STEP CONTROL GUIDANCE

Figure 2.37 illustrates how the simulator advances from the start of the simulation to the end, and shows two user defined report steps, each containing two simulator selected time steps. Each time step within a report time step, contains one to three Newton iterations, and each Newton iteration contains a various number of linear iterations.

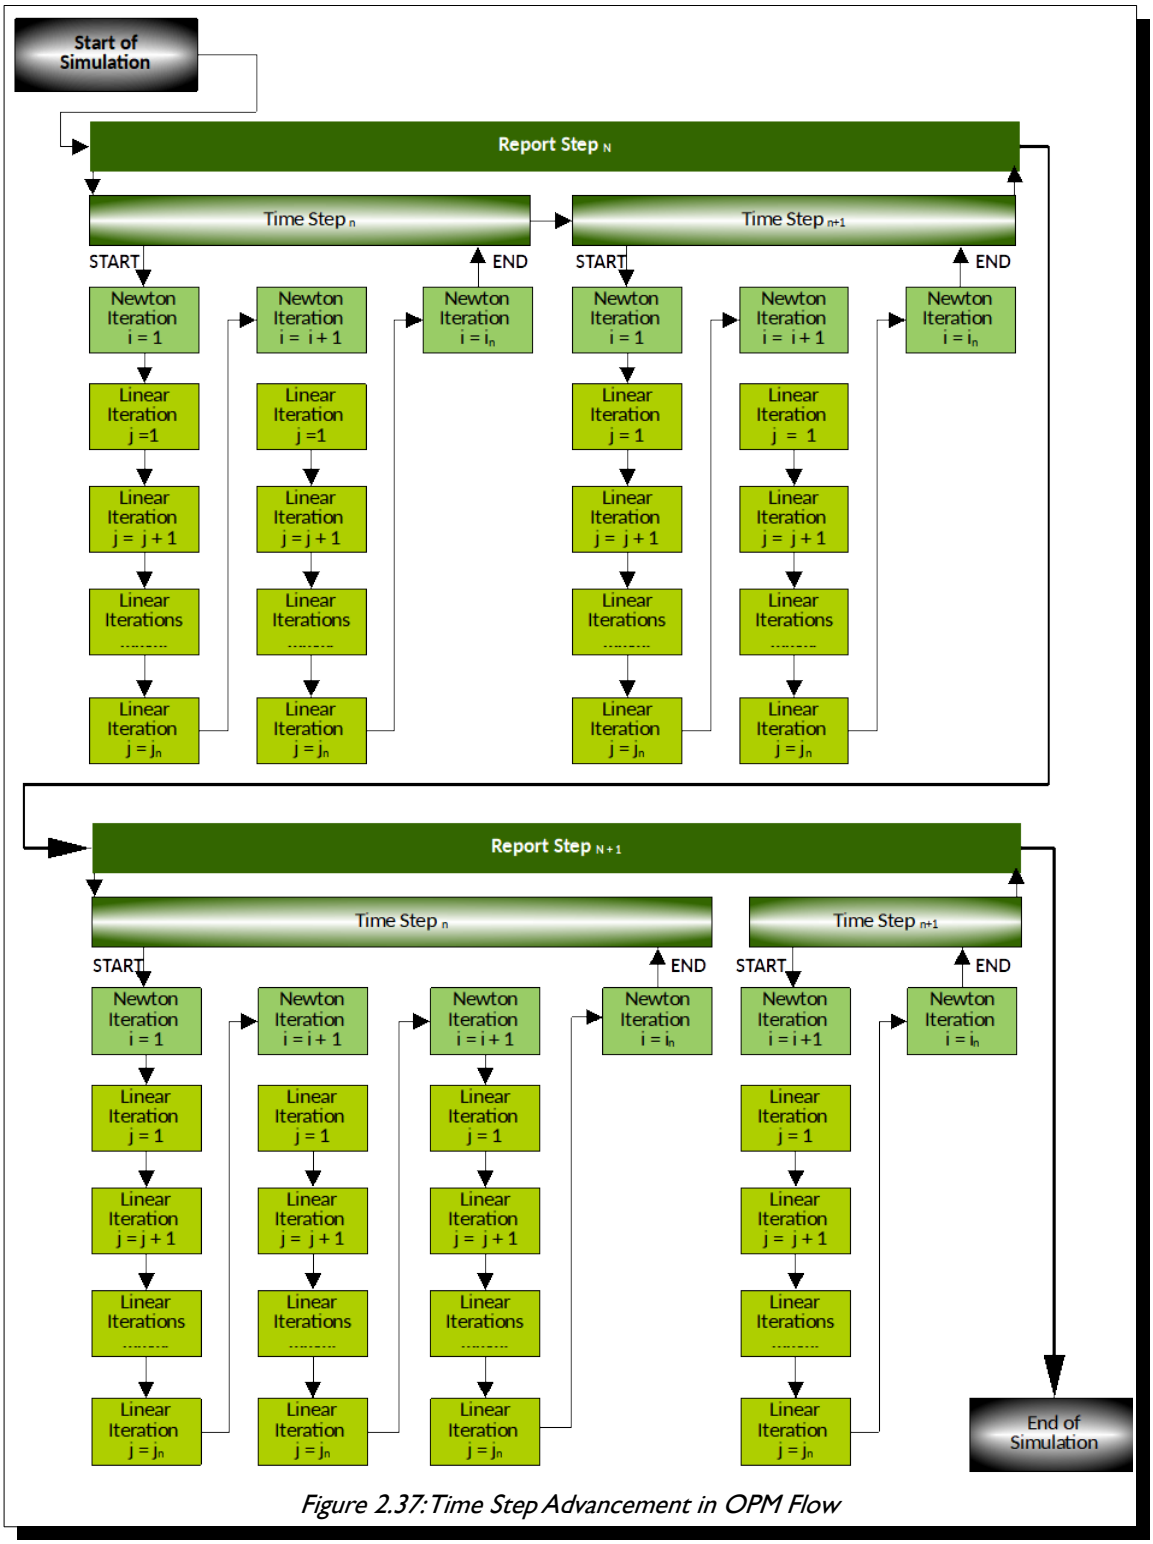

Figure 2.37: Time Step Advancement in OPM Flow

In an actual model the number of time steps are determined by the simulator's internal adaptive time stepping algorithm, combined with any user settings overriding the internal stepping algorithm and parameters. The default initial time step of one day can overwritten via either the command line parameter:

```
--initial-time-step-in-days
```

or via the *TUNING - Numerical Tuning Control* keyword in the SCHEDULE section, that offers more flexibility, as the initial time step size can be reset at various report time steps, by repeating the keyword and setting TUNING(TSINIT) to a given value. Alternatively, TUNING(TSMINZ) may be used to define the minimum length of all time steps. Note, however, the simulator only reads the first record of the TUNING keyword if, and only if, the following command line parameter has been activated:

```
--enable-tuning
```

One can also set the maximum time step size via both the command line parameter:

```
--solver-max-time-step-in-days
```

or via the TUNING(TSMAXZ) parameter, that defines the maximum length of the next time step following TUNING(TSINIT).

There are many other time stepping command line parameters, including those that are equivalent to all the first record parameters on the TUNING keyword; however, provided there are no data inconsistencies within the input deck, resetting the maximum time step size from the default value of 365 days will improve numerical performance. Typically the default value of 365 days is not binding, as the report time steps are more restrictive. So for example, in a history matching model, the production data is normally entered on a monthly basis, so the maximum report time step size would be 31 days. Even so, time step chops may still occur even in this scenario, and therefore reducing the maximum time step to half a month, that is 16 days may avoid time step chops. Sixteen days is preferred over 15 days as the maximum time step, because it enables only two successful time steps to complete a 31 day month (a 16 day plus a 15 day time step). If 15 days was used for the maximum time step size, then one would need three successful time steps to complete a 31 day month. In some cases using 11, or even a five day maximum time step may increase computational efficiency by avoiding expensive computational time step chops.

Basically, one has to balance the maximum length of time steps with the required number of time steps to reach the end of the run, versus the total elapsed time[55]. Time steps chops are computationally expensive and thus should therefore be minimized in order to reduce run times.

Figure 2.38 shows a typical report step and time step report from the simulator that contains two time step chops shown in the red outline boxes. Here the simulator is at:

1) Report step 15 (Current Step) out of the 33 steps (End Step) that are are needed to complete the run. Report step 15 is at October 9th, 1967 and the simulator's internal adaptive time stepping algorithm has determined that the next time step is 50 days.

2) As requested, the simulator writes out a restart record at report step 15, that is October 9th, 1967.

3) The simulator then attempts to advance 50 days, but fails due to a *Numerical problem encountered*, that is either the non-linear or linear solver failed to convergence within the maximum number of iterations. Thus, the time step was chopped from 50 days to 16.5 days, and simulator restarts again from report step 15, that is October 9th, 1967 and attempts to advance to October 25th, 1967. The 16.5 day time step converges in three Newton iterations using a total of 342 linear iterations, and the simulator has advanced to October 25th, 1967. Thus, for the next time step the simulator's internal adaptive time stepping algorithm has determined that the next time step should be 33.5 days.

4) The simulator then attempts to advance 33.5 days, but again fails due to a *Numerical problem encountered*, that is either the non-linear or the linear solver again failed to convergence within the maximum number of iterations. Thus, the time step was chopped form 33.5 days to 11.055 days, and

[55] *Elapsed real time, real time, wall-clock time, or wall time is the actual time taken from the start of a simulation to the end. In other words, it is the difference between the time at which the simulation finishes and the time at which the simulation started.*

simulator restarts again for report step 15, but from the last successful time step, that is October 25th, 1967 and attempts to advance to November 5th, 1967.

5) The 11.055 day time step converges in three Newton iterations using a total of 317 linear iteration, and the simulator has advanced to November 5th, 1967. For the next time step, the simulator's internal adaptive time stepping algorithm has determined that the next time step should be 22.445 days to coincide with the next report time step (report step 16) at November 28th, 1967.

6) Again, the 22.445 day time step is successful and converges in three Newton iteration using a total of 318 linear iterations.

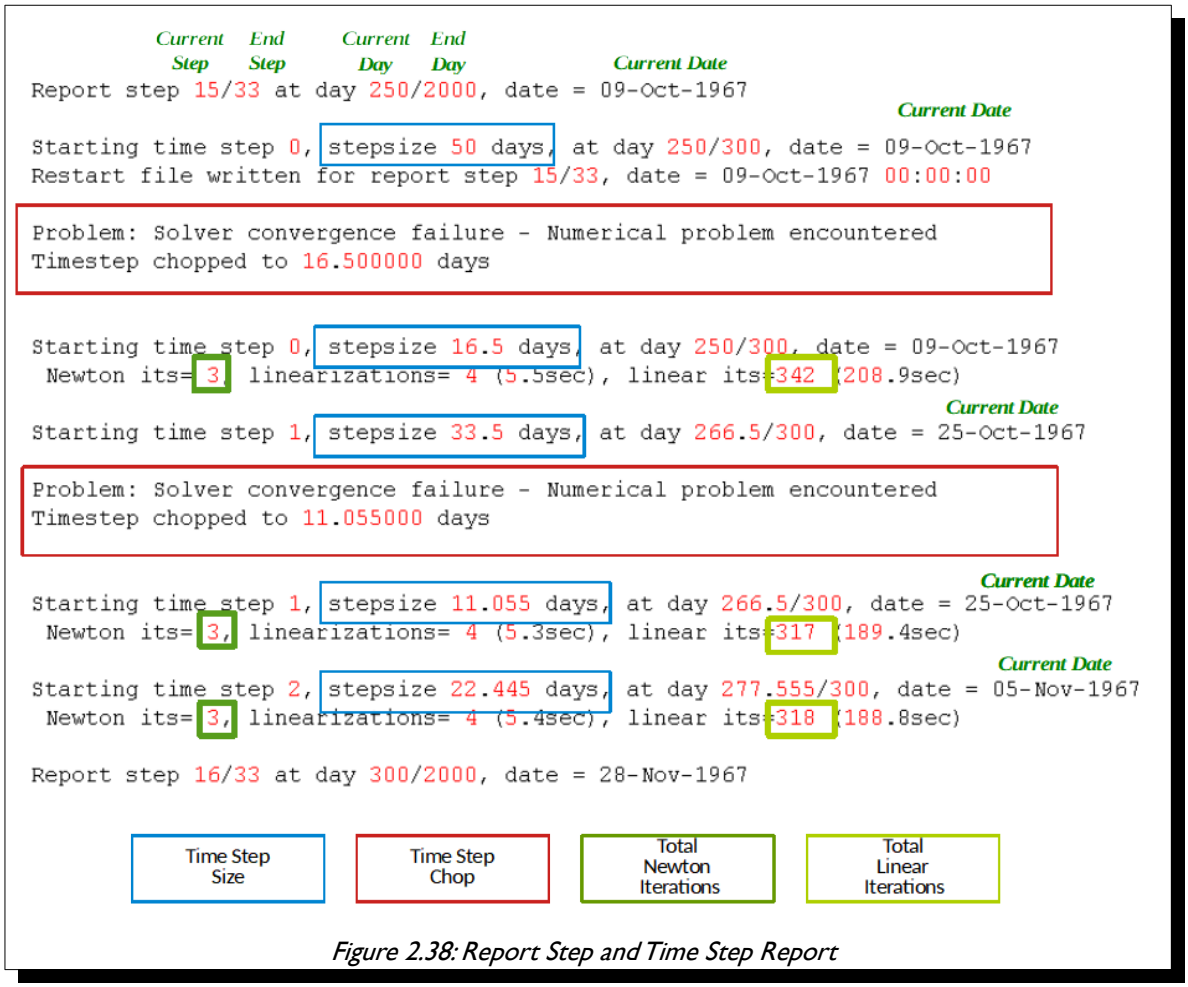

Figure 2.38: Report Step and Time Step Report

If the maximum time step was set to 16 days then advancing 50 days to November 28th, 1967 would take four time steps with a good chance of avoiding time step chops and thus reducing run times.

Various command line parameters can be used to control the behavior of the time stepping algorithm, as summarized in the Table 2.4, that lists the important time stepping control parameters for the simulator, including the TUNING equivalent parameters where applicable.

Major Solver Time Stepping Controls			
No.	**Command Line Parameter**	**TUNING Keyword Equivalent**	**Description**
1	--initial-time-step-in-days	TSINIT	A real double precision value that sets the size of initial time step in days. The default value is one day. Note that as the TUNING keyword can be entered multiple times, then TUNING(TSINIT) can be reset multiple times, whereas as *--initial-time-step-in-days*, is only set once at the beginning of the run.
2	--solver-growth-factor	TSDIFF	A real positive value that specifies the growth factor a time step can be increased by when recovering from one or more time step chops, subject to the maximum allowable time step size set by the *--solver-max-time-step-in-days* parameter. For example, if the current time step has converged at 5 days after a time step chop, and --solver-growth-factor is set to the default value of 2.0, then the next time step will be 2.0 * 5 days, that is at 10 days.
3	--solver-max-growth	TSFMAX	A real positive value that specifies the maximum growth factor a time step can be increased by after a report time step. subject to the maximum allowable time step size set by the --solver-max-time-step-in-days parameter. Thus, if the current time step has converged at 5 days after at a report step, and --solver-max-growth is set to the default value of 3.0, then the next time step will be 3.0 * 5 days, that is at 15 days.
4	--solver-max-restarts		A positive integer that defines the number of allowed consecutive restarts (or time step chops) before the simulation is terminated. Here the default value is 10. TUNING(TSMCHP) sets the minimum length of all chopped time steps.
5	--solver-max-time-step-in-days	TSMAXZ	A real positive double precision value that specifies the maximum allowed time step size in days. The default value of 365 days is really used in practise due to the report time steps being more restrictive, although in some specialized models (CO2 long term prediction cases) this may indeed be the upper limit. As mentioned previously, if the time steps chops are mostly occuring when the time step size is greater than Δt, then setting this parameter to a value less than Δt may reduce the number of time step chops. Provided of cause the value of Δt is reasonable.

6	--solver-min-time-step	TSMINZ	A real positive double precision value that specifie the minimum size of a time step in days for field and metric units, and hours for laboratory units If a time step cannot converge without getting cut below this time step size the simulator will stop, unless overwritten by the --solver-continue-on-convergence-failure command line parameter (see Table 2.1 for further details). Note if the current time step is smaller than this minimum and has not been subject to a time step chop, then in some circumstances it may still be accepted due to other numeric controls.
7	--solver-restart-factor	TSFCNV	A real positive double precision value that specifies the time step chop factor of the time step after a convergence failure. For example, if the current non-convergent time step is 30 days and this parameter is set to the default value of 0.33, then the time step will be repeated using 0.33 * 30 days as the time step, that is 9.9 days.
Notes: 1) Cells colored orange under the TUNING Equivalent Keyword column with no TUNING keyword parameter do not have an equivalent OPM Flow command line parameter.			

Table 2.4: Major Solver Time Stepping Controls

Note

OPM Flow also has a series of command line parameters of the form *--time-step** that are subordinate to the *--solver** series of command line parameters. The former, *--time-step**, are used to select the time step control algorithm and associated parameters, and in general should only be used by users with appropriate experience.

As mentioned above, the *--time-step** series of command line parameters should in general not be used; however, the following parameter may be useful if group and well events are resulting in time step chops:

```
--time-step-after-event-in-days
```

If the simulation is running smoothly with taking monthly historical report time steps, except for when a new well is bought on stream in a given month, or a group control is reset resulting in a significant change in production or injection, and the event causes time step chops, then using *--time-step-after-event-in-days* may improve the situation. The parameter can be used to automatically enforce a small time step when an event occurs, thus reducing the probability, or even eliminates a time step chop. Typically, a one or five day time step is used, as per:

```
--time-step-after-event-in-days=5.0
```

The drawback of cause is that control is applied to the complete run, which again needs to be taken into consideration.

Alternatively, one could use the NEXT or NEXTSTEP keywords in the SCHEDULE section, to incorporate similar behavior at specific times in the SCHEDULE section. See *NEXT – Maximum Next Time Step Size (Alias for NEXTSTEP)* or *NEXTSTEP – Maximum Next Time Step Size* for further information.

2.4.4 NEWTON-RAPHSON SOLVER ITERATION CONTROLS (NON-LINEAR ITERATIONS)

Figure 2.39 shows typical time step output for two report time steps, March 1st and April 1st, 2022; with both solving the equations with two Newton iterations per time step, and between four to six linear iterations per time step. The numerical count for the number of linearizations, is the number of times the Jacobian and the residuals have been constructed, and is generally one more than the number of Newton iterations. Figure 2.39, thus indicates very good performance, especially as the first iteration is taken from the previous successful time step. Note however, that the model is only using five day time steps in this case, which significantly contributes to the convergence stability of both the non-linear and linear solvers.

Figure 2.39: Report Step and Time Step Summary Reporting Example

The number of Newton iterations taken to solve a time step is indicative of the degree of ease the simulator has in converging to a solution, with higher numbers of iterations indicating an increasingly difficult problem.

Note, unlike Figure 2.39, the number of non-linear iterations will vary as the simulation progresses, with periods of relatively efficient convergence and periods where the simulator is struggling to reach non-linear convergence. The latter is normally associated with operational events, for example new wells being brought on stream, major changes to group controls etc.

Note

As mentioned previously, in general the number of Newton iterations is indicative of the ease of convergence, with one to three iterations indicating that converge was relatively easy and efficient, four to nine iterations indicating an increasingly difficult problem, and greater than ten would tend to suggest that there may be an issue with the model.

It is important to stress that the convergence of the non-linear solver, is very dependent on the accuracy of the linear solver. If the accuracy of the linear solver is too relaxed or is not fully converged. For example, if the linear solver solution is not sufficiently converged, then the non-linear solution may no longer be well-posed[56]. That is the solution starts digressing from the true solution, and additional iterations only exasperate the problem. Normally, under these circumstances the OPM Flow will chop the time step, which should correct the divergence by reverting to previous converged time step. However, if the time step is too small to chop and the run continues with the minimum time step, then the divergence from the true solution will continue. This may manifest itself with various error messages and NaNs ("Not a Number"), or eventually with the simulator aborting. Figure 2.40 shows an example of this behavior.

[56] *A problem in differential equations is said to be well-posed if: (1) a solution exists; (2) that the solution is unique; (3) and the solution changes continuously with the changes in the data.*

```

Figure 2.40: Time Step Summary Showing Non-Convergence Example.

Fortunately, OPM Flow has various controls that can resolve these type of issues similar to the commercial simulator, and in addition, and unlike the commercial simulator, OPM Flow has several linear solvers and preconditioners that increase the likelihood a solution may be found for various non-convergence issues.

As mentioned previously in section 1.6 Numerical Solution of Equations, convergence is achieved when $R(y_n)$, the residual, in equation (2.5), satisfies a given tolerance.

$$J(y_n)(y_{n+1} - y_n) = -R(y_n) \tag{2.5}$$

Where:

$J(y_n)$ = the Jacobian matrix,

y_n = the solution of the non-linear equations at the nth non-linear iteration, and

y_{n+1} = the solution of the non-linear equations iteration at the n+1 iteration.

However, as the iterations proceed during a time step the residual convergence criteria is reduced in an effort to avoid a time step chop. Thus, by relaxing the convergence criteria as the non-linear iterations progress, the simulator is attempting to avoid throwing away all the previous work performed in trying to reach a solution for the time step.

From the user prospective, there are several command-line options that can be used to control the Newton-Raphson solver, in particular:

1) To modify the maximum number of non-linear iterations per time step, the following command line parameter can be used:

```
--newton-max-iterations
```

Although, the default value of 20 is sufficiently large, that it should not be necessary to increase this value.

2) There is also a command that sets the minimum number of Newton iterations per time step used by the simulator.

```
--newton-min-iterations
```

The default value of one ensures that at least one Newton iteration is performed after the previous time step. Increasing this parameter, to say two for example, may help convergence in difficult time steps, by ensuring slightly more accurate results in preceding "easy" time steps.

3) Thirdly, the mass balance error as a reservoir average saturation error, and can be use to slacked or tighten the material balance tolerance.

```
--tolerance-mb
```

In general, if the non-linear solver is having difficulty in converging, then tightening the linear mass balance error as a reservoir average saturation error, may help the non-linear solver converge more rapidly.

4) Fourthly, maximal local residual error can be slacked or tighten using:

```
--tolerance-cnv
```

command line parameter. And may be used to set the maximal local residual error.

For completeness, Table 2.5 lists the major non-linear command line parameters used to control the behavior of the non-linear solver, including those that relate to relaxed convergence criteria. However, in general it is recommend not modify these parameters, unless one has the sufficient expertise in this area.

Major Newton-Raphson Solver Controls			
No.	**Command Line Parameter**	**TUNING Keyword Equivalent**	**Description**
1	--newton-max-iterations	NEWTMX	A positive integer that defines the maximum number of Newton iterations per time step used by the simulator. The default value is 20 which compares to the commercial simulator's value of 12, so there should not really be a requirement to increase this parameter.
2	--newton-min-iterations	NEWTMN	A real positive integer that sets the minimum number of Newton iterations per time step used by the simulator. The default value of one ensures that at least one Newton iteration is performed after the previous time step. Increasing this parameter, to say two for example, may help convergence in difficult time steps, by ensuring slightly more accurate results in preceding "easy" time steps.

Major Newton-Raphson Solver Controls			
No.	**Command Line Parameter**	**TUNING Keyword Equivalent**	**Description**
3	--newton-max-relax		A real positive value that sets the maximum relaxation factor of a Newton iteration used by the simulator. The default is 0.5. In general, it is not recommended to modify this parameter.
4	--newton-relaxation-type		A character string that defines the type of relaxation used in Newton's method, the default is dampen. In general, it is not recommended to modify this parameter.
5	--max-newton-iterations-with-inner-welliterations	MXWSIT	A positive integer that specifies the maximum Newton iterations with inner well iterations. The default value is eight, the same as the commercial simulator. If there are issues with well convergence, then sometimes increasing this value, to say 12, may improve the situation.
6	--min-strict-cnv-ite		A positive integer that sets the minimum number of Newton iterations before relaxed tolerances are used for the CNV convergence criterion. The default value is zero, means that relaxed convergence criterion is applied after the initial iteration., that is iteration zero in Figure 2.42 in section 2.4.5 Linear Solver Controls and Options. Increasing this parameter may improve convergence by applying stricter convergence controls over additional Newton iterations, but may also increase the number of Newton iterations over a time step before the time step is accepted.
7	--tolerance-cnv		A real positive double precision value that specifies the maximum non-linear tolerance error. This is the local convergence tolerance (maximum of local saturation errors). The default value is 0.01
8	--tolerance-mb		A real positive double precision value that sets the maximum mass balance error, that is the tolerated mass balance error relative to total mass present. the default value is 1.0 x 10-6.

Notes:

1) Cells colored gray under the No. column, are not recommend to be modified.
2) Cells colored orange under the TUNING Equivalent Keyword column with no TUNING keyword parameter do not have an equivalent OPM Flow command line parameter.
3) Cells colored orange under the TUNING Equivalent Keyword column with a TUNING keyword parameter, means OPM Flow does not support reading this parameter from the TUNING keyword and therefore the OPM Flow command line option should be used.

Table 2.5: Newton-Raphson Solver Controls

Detailed descriptions of all of the command line parameters are given in Table 2.1 in section *2.2 Running OPM Flow 2023-10 From The Command Line*.

2.4.5 LINEAR SOLVER CONTROLS AND OPTIONS

There are numerous options for the linear solver, which can be overwhelming even for the most experienced users, given the rich feature set enabled by the various command line parameters. Fortunately, the simulator summarizes the options in use in the *Linear Solver Property Tree* printed in both the *.PRT and *.DBG files, right after processing the input data and just before the simulation starts.

```
Property tree for linear solver:
{
    "tol": "0.01",
    "maxiter": "200",
    "verbosity": "1",
    "solver": "bicgstab",
    "preconditioner": {
        "type": "ParOverILU0",
        "relaxation": "0.90000000000000002",
        "ilulevel": "0"
    }
}
```

Figure 2.41: Linear Solver Property Tree

Figure 2.41 above shows an example of the Linear Property Tree, based on using mostly the linear solver default parameters. Here the tol value of 0.01 is equivalent to the --tolerance-cnv command line parameter, and maxiter is equivalent to --linear-solver-max-iter, as summarized in Table 2.6 for all the other parameters.

No.	Property Tree Parameter	Equivalent Command Line Parameter
1	tol	--tolerance-cnv
2	maxiter	--linear-solver-max-iter
3	verbosity	--linear-solver-verbosity
4	solver	--use-gmres=false
5	preconditioner	
6	type	--linear-solver
7	relaxation	--ilu-relaxation
8	ilulevel	--ilu-fillin-level

Notes:

1) BiCGSTAB stands for Biconjugate Gradient Stabilized linear solver.
2) GMRES is for the Generalized Minimal Residual linear solver.

Table 2.6: Linear Solver Property Tree versus Command Line Parameters

Table 2.7 list the major linear solver command line parameters discussed in this section.

Figure 2.42 shows typical output for the linear solver for the March 1st report step advancing to the next report step. Naturally, the Newton and linear iteration counts are same as for Figure 2.39 for the common periods; however, oil, gas and water material balance values are printed for each non-linear iteration, together with the respective convergence values.

Time Step | Newton Iteration | Total Linear Iterations | Material Balance | Convergence Tolerance

Figure 2.42: Time Step Summary Reporting Linear Solver Example

The total number of linear iterations displayed in Figure 2.42 is the total number of iterations for all the non-linear iterations, not for a particular non-linear iteration. To get the number of linear iterations per non-linear iteration use the following command line parameter:

```
--linear-solver-verbosity=1
```

Which will produce a report similar to that shown in Figure 2.43, with the IT parameter indicating the number of linear iterations for the given Newton iteration.

```

```

Figure 2.43: Number of Linear Iterations Per Newton Iteration Report Example

As mentioned previously, the convergence of the non-linear solver is dependent on the accuracy of the linear solvers. Solving the linear system to a loose accuracy may lead to poor convergence of the non-linear solver. The tuning of the time stepping procedure, and the tolerance used in the linear and non-linear solvers are highly related, and optimal choices are case and problem dependent.

From the user prospective, there are several command-line options that can be used to configure and control the linear solver, in particular:

1) Using an alternative linear solver by changing

   `--use-gmres`

   The default value of false sets the linear solver to the Biconjugate Gradient Stabilized ("BiCGSTAB") linear solver, whereas a value of true will set the linear solver to use the Generalized Minimal Residual linear solver ("GMRES"). If the default linear solver is not converging then changing to the GMRES solver may help. Note, that the GMRES linear solver has a slightly higher memory consumption, as it stores some of the previous search iterations as part of the optimization process. The default number of search iterations stored is 15, which means 14 more vectors than BiCGSTAB solver.

2) Changing the linear solver preconditioner can dramatically improve the performance of the linear solver, which is accomplished by the following command line parameter:

   `--linear-solver`

   In many cases using a Constraint Pressure Residual ("CPR") preconditioner instead of the default Incomplete Lower-triangular Upper-triangular factorization with level of fill in 0 ("ILU0"), will result in difficult problems being solved at the expense of additional work. For example, model two in the Tenth SPE Comparative Solution Project[57], fails to run using the default preconditioner, but runs satisfactory with the CPR preconditioner. Note that the commercial simulator also has a CPR option

[57] *Christie, M.A., and M.J. Blunt. "Tenth SPE Comparative Solution Project:A Comparison of Upscaling Techniques." SPE Res Eval & Eng 4 (2001): 308–317. doi: https://doi.org/10.2118/72469-PA.*

that is implemented via the CPR keyword in the RUNSPEC, but the implementation is different to that of OPM Flow.

3) And finally increasing the number linear iterations may be appropriate, via:

```
--linear-solver-max-iter
```

that defines the maximum number of linear iterations. Sometimes increasing this value may improve performance.

Major Linear Solver Controls			
No.	**Command Line Parameter**	**TUNING Keyword Equivalent**	**Description**
1	--linear-solver		"ilu0"A defined quoted character string that sets the configuration of the solver, valid values are: 1) ilu0 (default), 2) cpr (an alias for cpr_trueimpes)[58] [59] and [60] 3) cpr_quasiimpes, 4) cpr_trueimpes, 5) cprw, 6) amg,[61] or 7) a file name that has the extension ".json", that contains the linear solver configuration parameters. Option (5) extends the existing Constrained Pressure Residual ("CPR") preconditioner to include wells. This option can also be invoked via the CPR keyword in the RUNSPEC section; however, the command line parameter takes precedence. For option (6) one enters a character string enclosed in quotes that defines the filename of a JSON configuration file for the flexible linear solver system. In this case the file extension should be '.json'. Note that the *.PRT file contains the "Property tree for the linear solver" listing, which is the JSON specification of the current case, and can be used as a guide to configure a user specific linear solver JSON file. The default is "ilu0". **The option "cpr" now is an alias for "cprw" instead of "cpr_trueimpes".**

Major Linear Solver Controls			
No.	**Command Line Parameter**	**TUNING Keyword Equivalent**	**Description**
2	--linear-solver-ignore-convergence-failure		A Boolean value set to true or false that if set to true convergences failures in the linear solver are ignored. This option should be used with care, as the results may be unreliable.
3	--linear-solver-max-iter	LITMAX	A positive integer value that defines the maximum number of linear iterations.
4	--linear-solver-reduction		A real positive double precision value that sets the minimum reduction of the residual for the linear solver. The linear solver convergences when the residual is reduced sufficiently. In general, it is not recommended to modify this parameter.
5	--linear-solver-require-full-sparsity-pattern		A Boolean value set to true or false that if set to true the simulator will produce the full sparsity pattern for the linear solver. n general, it is not recommended to modify this parameter.
6	--linear-solver-restart		A positive integer value that sets the number of iterations after which GMRES is restarted. n general, it is not recommended to modify this parameter.
7	--use-gmres		A Boolean value that when set to true OPM Flow will use Generalized Minimal Residual ("GMRES") solver instead of Biconjugate Gradient Stabilized ("BiCGSTAB") as the linear solver within the Newton iterations.

Notes:

1) Cells colored gray under the No. column, are not recommend to be modified.
2) Cells colored orange under the TUNING Equivalent Keyword column with no TUNING keyword parameter do not have an equivalent OPM Flow command line parameter.
3) Cells colored orange under the TUNING Equivalent Keyword column with a TUNING keyword parameter, means OPM Flow does not support reading this parameter from the TUNING keyword and therefore the OPM Flow command line option should be used.

Table 2.7: Linear Solver Controls

Again Detailed descriptions of all of the command line parameters are given in Table 2.1 in section 2.2 Running OPM Flow 2023-10 From The Command Line.

CHAPTER 3: KEYWORD DOCUMENTATION STRUCTURE

3.1 INTRODUCTION

The OPM Flow manual is constructed in a manner to enable the reader to reference various parts of the document by using the table contents or by simply pressing on a link embedded in the text. This automatic cross referencing has been extensively employed to ensure effective documentation of the keywords used by the simulator.

There are several key features that can be used to navigate the manual in an efficient manner. The first is the "footer" which can be used to move to various sections in the manual. For example the "Table of Contents" footer shown below:

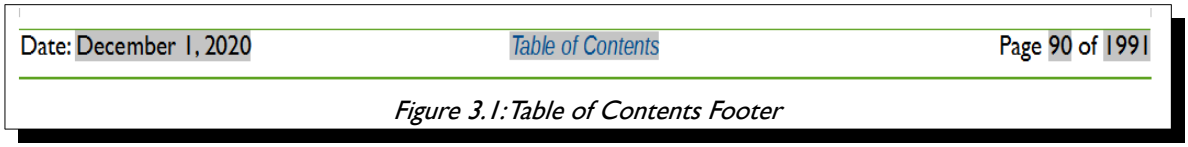

Figure 3.1: Table of Contents Footer

Allows the reader to move to the Table of Contents by clicking on the link (highlighted in italic blue text on a gray background in Figure 3.1). Note also that the entries in the table of contents are also "clickable" enabling the reader to move to the desired entry.

The second type of footer is the "Keyword Index" footer that also contains the Table of Contents link mentioned above. This footer is illustrated in Figure 3.2 and is displayed on a keyword definition page.

Figure 3.2: Keyword Index Footer

Clicking on a letter (highlighted in italic blue text on a gray background in) takes the reader to an alphabetic listing of all the keywords beginning with the selected letter (Figure 3.3).

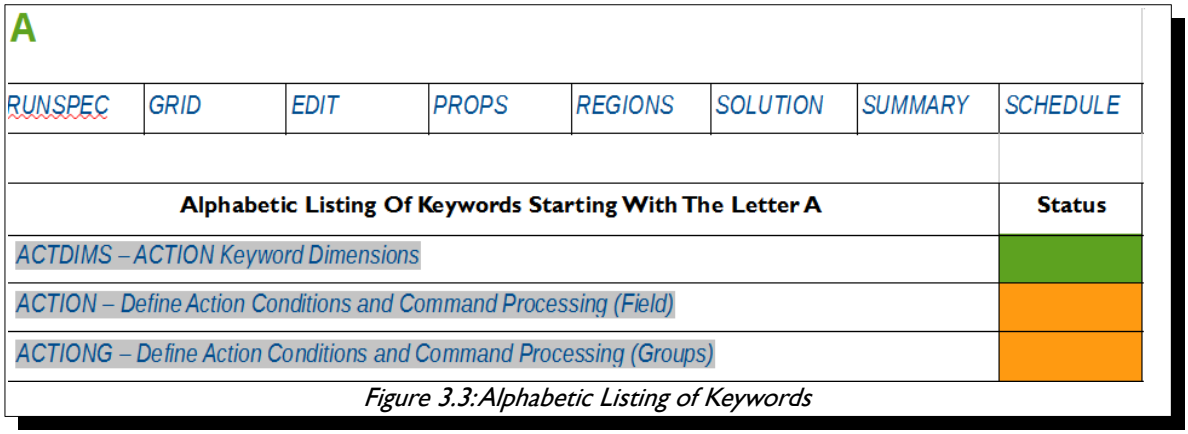

Figure 3.3: Alphabetic Listing of Keywords

The list is color coded, so one instantly knows what keywords are implemented, with green colored cells indicating the keyword is available and is mostly or fully implemented. Cells colored orange show that keyword is recognized but not implemented in OPM Flow. Finally, cells colored red mean that keyword is available in the commercial simulator but has not been implemented in OPM Flow, and may cause an error if used in the input deck. Clicking on a keyword in the list it will move the reader to the keyword definition. Note also that clicking one of the section names, RUNSPEC, GRID, etc., in Figure 3.3, will take the reader to the beginning of the selected section.

Finally, in the PDF version of the manual if one displays the "bookmarks" in the PDF reading software one can jump to a particular keyword or section without having to scroll up or down.

3.2 KEYWORD DEFINITIONS

Each keyword is defined in it's own section that contains a section header, that contains the keyword name in capital letters followed by a brief description of the keyword's function. This is then followed by Keyword Table Section which defines the status of the keyword and which sections of the input deck the keyword can be utilized. Table 3.1 illustrates a typical Keyword Table Section defining the keyword status with the various OPM Flow sections.

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Table 3.1: Example Keyword Table Section

The cells are colored in such a manner as to quickly indicate to the reader the keyword's section availability and function availability, with green colored cells indicating the keyword is available for this section and is mostly or fully implemented. Cells colored gray indicate that keyword cannot be used in that particular section, and cells colored orange show that cell is only partially implemented within OPM Flow, for example OPM Flow may simple just recognize the keyword and ignore the keyword's function. Finally, cells colored red mean that keyword is available in the commercial simulator but has not been implemented in OPM Flow. In this scenario the keyword should not be used in OPM Flow as it will result in unpredictable results, including causing the simulator to abort or throw an exception.

3.3 MULTI-SECTION KEYWORDS

As there are numerous keywords that can be used within multiple OPM Flow sections of the input file, for example the *ADD* and *EQUALS* keywords, there is a need to avoid duplication of the keyword definitions but at the same time attempt to define only those keywords for a given section. Thus for multi-section keywords, the keyword is defined in the first available section that the keyword can be found. The Keyword Table Section as shown below for the *ADD* keyword below, indicates which sections the keyword can be utilized.

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Table 3.2:ADD Keyword Table Section

Here the keyword can be used in the GRID, EDIT, PROPS, REGIONS and SOLUTION sections as indicated by those cells colored green and not for the cells colored in light gray. In subsequent sections that the keyword can be used, there is a brief description description with a link to the full description of the keyword, as shown below for the ADD keyword.

> The ADD keyword adds a constant to a specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the ADD keyword is being applied. See *ADD – Add a Constant to a Specified Array* in the GRID section for a full description.

A complete list of keywords in alphabetic order is given in section *APPENDIX A: KEYWORD INDEX - ALPHABETIC LISTING* , and clicking on a specific keyword will take the reader to the keyword definition in a particular section.

3.4 KEYWORD FORMATS

All keywords in OPM Flow should be entered in capital case and start in column one, lowercase entry of keywords will be produce errors and keywords not starting in column one will not be recognized. There are five types of keyword format types used by OPM Flow for data input. The description of the five types is given in the next three section together with some examples.

3.4.1 KEYWORD FORMAT TYPE – COMMENT

Comments in the input deck can occur anywhere in the file are preceded by "--" in columns one and two, for example for the EQUL keyword:

```
--
--       MAX     MAX     RSVD    TVDP    TVDP
--       EQLNUM  DEPTH   NODES   TABLE   NODES
EQLDIMS
         9       1*      20      1*      1*                                  /
```

In addition, comments can be place after "/" that terminates a record entry as shown below;

```
--
-- -- ARRAY    CONSTANT --  ---------- BOX ---------
--                         I1  I2   J1  J2   K1  K2
MULTIPLY
   'PERMZ'     0.50000     1*  1*   1*  1*   1*  1* / PERMZ * 0.5
/
```

3.4.2 KEYWORD FORMAT TYPE – ACTIVATION

This type of keyword format only consists of the keyword itself and is usually used to invoke a feature or to switch on or off a processing feature. The keyword is document by describing the functionality or action the keyword performs, followed by an example. Examples of this type of keyword include API (to switch on API tracking), GAS (to activate the gas phase in the model), ECHO (to switching echoing of the input file to the output file), and SKIP (for skipping parts of the input deck). For example the GAS keyword in the RUNSPEC section would be described as:

Description

This keyword indicate that the gas phase is present in the model and must be used for oil-gas, gas-water, oil-water-gas input decks that contain the gas phase. The keyword will also invoke data input file checking to ensure that all the required gas phase input parameters are defined in the input deck.

There is no data required for this keyword.

Example

```
--
--       GAS PHASE IS PRESENT IN THE RUN
--
GAS
```

The above example declares that the gas phase is active in the model.

3.4.3 KEYWORD FORMAT TYPE - VECTOR (ROW VECTOR)

Vector based keywords consist of the keyword followed by a vector of parameters on a separate line and may consists of multiple lines of vectors with each line representing a data set (see the second example for this type of vector keyword). The vector may contain integer, real and character parameters depending on the keywords requirements. This type of keyword is documented by describing the functionality or action the keyword performs, a table describing the parameters associated with the keyword, followed by one or two examples on how to use the keyword. For example the DIMENS keyword in the RUNSPEC section would be described as:

Description

DIMENS defines the dimensions of the model entered as integer vector. The keyword can be used with all grid types.

No.	Name	Description	Default
1	NX	The number of grid blocks in the x direction for Cartesian grids or the number of grid blocks in the r direction for radial grids	None
2	NY	The number of grid blocks in the y direction for Cartesian grids or the number of grid blocks in the theta direction for radial grids.	None
3	NZ	The number of grid blocks in the z direction for both Cartesian and radial grids.	None
Notes: 1) The keyword is terminated by a "/".			

Table 3.3: DIMENS Keyword Description

Note that NX, NY and NZ are not maximum values but the actual size of the grid. OPM Flow applies these parameters when reading in particular data sets. For example if NX, NY, and NZ are set to 10, 10 and 10 respectively, then for the grid property data like PORO; OPM Flow expects to read in 10 x 10 x 10 or 1,000 porosity values for the PORO array. If the number of porosity values is not equal to 1,000 then OPM Flow will produce an error.

Example

```
--
--        MAX      MAX      MAX
--        NDIVIX   NDIVIY   NDIVIZ
DIMENS
          46       112      22                                                  /
```

The above example defines the dimensions for the Norne model of 36 cells in the x direction, 122 cells in the y direction and 22 cells in the z direction.

For vector keywords that have parameters associated with units, then there is a slightly different table format to that used above to take into account documenting the default values for the three sets of units supported by OPM Flow, for example for the ROCK keyword is describe as follows:

Description

ROCK defines the rock compressibility for various regions in the model. The number of ROCK vector data sets is defined by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section and the allocation of the ROCK tables to different grid blocks in the model is done via the PVTNUM keyword in the REGION section. One data set consists of one record or line which is terminated by a "/".
This keyword must be defined in the OPM Flow input deck.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	Pref	Pref is a real number defining the reference pressure for the other parameters for this data set.			
		psia 1.032	barsa 1.032	atma 1.032	Default
2	Cf	Cf is a real number defining the rock compressibility at the reference pressure, Cf(Pref) and is defined as: $$C_f = -\frac{1}{V}\left(\frac{dV}{dP}\right)$$			
		1/psia 0.0	1/barsa 0.0	1/atma 0.0	Defined
Notes: 1) The each data set terminated by terminated by a "/" at the end of the line, there is no terminator for the keyword.					

Table 3.4: ROCK Keyword Description

Example

The following shows the PVTW keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to one.

```
--
-- ROCK COMPRESSIBILITY
--
-- (1) REFERENCE PRESSURE IS TAKEN FROM THE HCPV WEIGHTED RESERVOIR PRESSURE
--     AS THE PORV IS ALREADY AT RESERVOIR CONDITIONS (FLOW USES THE REFERENCE
--     PRESSURE) TO CONVERT THE GIVEN PORV TO RESERVOIR CONDITIONS USING THE DATA
--     ON THE ROCK KEYWORD)
--
ROCK
    3566.9    5.0E-06                          / ROCK COMPRESSIBILITY REGION 1
    3966.9    5.5E-06                          / ROCK COMPRESSIBILITY REGION 2
    4566.9    6.0E-06                          / ROCK COMPRESSIBILITY REGION 3
```

There is no terminating "/" for this keyword.

In this case the example shows a multiple data set entry of the vector format keyword, with three ROCK data sets being defined by the keyword.

3.4.4 KEYWORD FORMAT TYPE – VECTOR (COLUMNAR VECTOR)

Columnar vector based keywords consist of the keyword followed by a columnar vector of parameters in a separate column for each parameter. The vector may contain integer, real and character parameters depending on the keywords requirements. This type of keyword is documented by describing the functionality or action the keyword performs, a table describing the parameters associated with the keyword, followed by one or two examples on how to use the keyword. For example the SWFN keyword in the PROPS section would be described as:

Description

The SWFN keyword defines the water relative permeability and water-oil capillary pressure data versus water saturation tables for when water is present in the input deck. This keyword should only be used if water is present in the run.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWAT	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the water saturation.			
		dimensionless	dimensionless	dimensionless	None
2	KRW	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the water relative permeability with respect to gas saturation. The first value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None
3	PCWO	A columnar vector of real values that are either equal or increasing down the column that defines the water-oil relative capillary pressure. If the SWATINIT keyword has been used to initialize the model then columnar vector has to be strictly monotonically increasing.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 3.3: SWFN Keyword Description

Example

```
--
--       WATER RELATIVE PERMEABILITY TABLES (SWFN)
--
SWFN
--       SWAT       KRW        PCOW
--       FRAC       FRAC       PSIA
--       --------   --------   -------
            0.15     0.00000     1*
            0.30     0.00050     1*
            0.40     0.00390     1*
            0.50     0.01500     1*
            0.60     0.04100     1*
            0.65     0.06250     1*
            0.70     0.09150     1*
            0.80     0.17850     1*
```

```
            0.90     0.31640     1*
            0.95     0.40960     1*
            1.00     0.52200     1*                          / TABLE NO. 1
```

The example defines two SWFN tables for use when water is present in the run. In the tables the water-oil capillary pressure data has been defaulted with "1*" and will be set to zero as there are no other values for the water-oil capillary pressure columns.

3.4.5 KEYWORD FORMAT TYPE – ARRAY

This type of keyword defines a property for the grid or an area of the grid using a previously entered BOX keyword to define the area where the property will be defined. For array data a full set of values for each element in the array is required. For example, the documentation for the PORO array would be:

Description

PORO defines the porosity for all the cells in the model via an array. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PORO	PORO is an array of real numbers assigning the porosity values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*100.0.			None
		dimensionless	dimensionless	dimensionless	
Notes: 1) The keyword is terminated by a "/".					

Table 3.3: PORO Keyword Description

See also the DX, DY and TOPS keywords to fully define a Cartesian Regular Grid.

Example

```
--
--  DEFINE GRID BLOCK POROSITY DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PORO
  300*0.300
/
```

3.5 INPUT FILE STRUCTURE

OPM Flow input files are similar to commercial simulators that are used in the oil and gas industry, that is the input file is separate into sections in an effort to avoid an engineer's input data errors and a computer programmer's code to interpret the data. OPM Flow has been designed, from an engineer's prospective and input structure to be similar to Schlumberger's industry wide ECLIPSE 100[62] simulator. Table 3.4 lists the various section together with a brief description of purpose of the section. As well as declaring if section is mandatory or not for a run to form a valid input deck.

Section Name	Description	Required Optional
RUNSPEC	This is the first section in the OPM Flow input file and defines the key parameters for the simulator including the dimensions of the model, phases present in the model (oil, gas and water for example), number of tables for a given property and the maximum number of rows for each table, the maximum number of groups, wells and well completions, as well as various options to be invoked by OPM Flow.	Required
GRID	Defines the basic grid properties, including structure, faults and various static rock properties (porosity, permeability etc.). Upon completion of reading this section, the software calculates the pore volume (PORV) for each and the transmissibilities (TRANX, TRANY and TRANX,) between all the cells, as well as calculating the transmissibilities of the Non-Neighbor Connections ("NNC")	Required
EDIT	The properties calculated by OPM Flow in the GRID section are available for editing in this section (PORV, TRANX etc.).	Optional
PROPS	This section defines the fluid properties for all the phases present in the run, for example oil viscosity, oil formation volume factor etc. The section also defines the rock flow properties as per the relative permeabilities and the distribution of the fluids based on the capillary pressure functions.	Required
REGIONS	The REGIONS section allows the engineer to define various regions in the model for reporting purposes and to define how the fluid and rock property defined in the PROPS section are allocated throughout the model.	Required
SOLUTION	Defines the parameters to initialize the model, fluid contacts, reservoir pressures etc., together with the data from the previous sections. This section, if requested, reports the initial in-place volumes for phases present in the model, as well as the average pressure for the various defined regions.	Required
SUMMARY[1]	Defines the time vector property data to be written out to various report output files for reviewing the results of the simulation. This data includes field, group, well and well completion production and injection data, for example field oil rate versus time. Grid block data can also be reported versus time as well, for example grid block pressure versus time[2].	Optional
SCHEDULE	The final section is the SCHEDULE that the defines the field, group and well parameters, targets and constraints that should be applied to the field, group or wells, numerical controls, the operating schedule and reporting requirements.	Required

[62] *ECLIPSE Industry-Reference Reservoir Simulator – Reference Manual 2019.1, Schlumberger.*

Section Name	Description	Required Optional

Notes:

1) Although the SUMMARY section is optional, it is nearly always included in order to obtain results from the simulation run.
2) The OPM ResInsight three-dimensional visualization software has a feature to display a grid block property change versus time, so it should not be necessary to export the grid block data to the SUMMARY report output files.

Table 3.4: OPM Flow Input Deck Sections

CHAPTER 4: GLOBAL SECTION KEYWORDS

4.1 INTRODUCTION

Keywords used in this section can be used in all input file sections, that is the RUNSPEC, GRID, EDIT PROPS, REGIONS, SOLUTION, SUMMARY and SCHEDULE sections.

4.2 DATA REQUIREMENTS

There are no data requirements for the GLOBAL section keywords, as all the keywords are optional and considered to utility keywords that can be used throughout the input deck. A complete list of these global keywords is given in Table 4.1.

No.	GLOBAL Keyword	Description	Section Applied
1	COLUMNS	*COLUMNS – Define Input File Column Margins*. The COLUMNS keyword defines the input file column margins; characters outside the margins are ignored by the input parser.	ALL
2	DEBUG	*DEBUG – Define the Debug Data to be Printed to File*. This keyword defines the debug data to be written to the debug file (*.DBG), it is ignored by OPM Flow.	ALL
3	ECHO	*ECHO – Activate Echoing of User Input Files to the Print File*. Turns on echoing of all the input files to the print file; note that this keyword is activated by default and can subsequently be switched off by the NOECHO activation keyword.	ALL
4	END	*END – Define the End of the Input File*. This keyword marks the end of the input file and can occur in any section. Any keywords and data after the END keyword are ignored.	ALL
5	ENDINC	*ENDINC – Define the End of an Include File*. This keyword marks the end of an include file specified on the INCLUDE keyword. When the ENDINC keyword is encountered in the INCLUDE file, input data is read from the next keyword in the current file.	ALL
6	ENDSKIP	*ENDSKIP – DeActivate Skipping of Keywords and Input Data*. Turns off skipping of keywords that was activated by the SKIP, SKIP100, or SKIP300 keywords.	ALL
7	EXTRAPMS	*EXTRAPMS – Activate Extrapolation Warning Messages*. The EXTRAPMS keyword activates extrapolation warning messages for when simulator extrapolates the PVT or VFP tables.	ALL
8	FORMFEED	*FORMFEED – Defined the Print File Form-Feed Character*. The keyword defines the form-feed character, or carriage control character, for the output print (*.PRT) run summary (*.RSM) files.	ALL
9	INCLUDE	*INCLUDE – Load Another Data File at the Current Position*. The INCLUDE keyword informs OPM Flow to continue reading input data from the specified INCLUDE file.	ALL
10	MESSAGE	*MESSAGE – Output User Message*. The MESSAGE keyword outputs a user message to the terminal, as well as to the print (*.PRT) and debug (*.DBG) files.	ALL

No.	GLOBAL Keyword	Description	Section Applied
11	MESSAGES	*MESSAGES – Define Message Print Limits and Stop Limits*. The MESSAGES keyword defines the print and stops levels for various messages.	ALL
12	NOECHO	*NOECHO – Deactivate Echoing of User Input Files to the Print File*. Turns off echoing of all the input files to the print file.	ALL
13	NOWARN	*NOWARN – Deactivate Warning Messages*. Turns off warning messages to be printed to the print file.	ALL
14	SKIP	*SKIP – Activate Skipping of All Keywords and Input Data*. The keyword turns on skipping of keywords until the ENDSKIP activation keyword is encountered.	ALL
15	SKIP100	*SKIP100 – Activate Skipping of Black-Oil Keywords and Input Data*. This keyword turns on skipping of black-oil keywords until the ENDSKIP activation keyword is encountered.	ALL
16	SKIP300	*SKIP300 – Activate Skipping of "Compositional" Keywords and Input Data*. Turns on skipping of "compositional" keywords until the ENDSKIP activation keyword is encountered.	ALL
17	WARN	*WARN – Activate Warning Messages*. Turns on warning messages to be printed to the print file (*.PRT); note that this keyword is activated by default.	ALL

Notes:

1) Note that not all keywords and features listed above are implemented in OPM Flow. Cells not colored in the No. column indicate the keyword is supported or partially supported by OPM Flow, cells colored gray indicate that the keyword is not applicable, and finally, cells colored in orange indicate keywords that are not supported by OPM Flow and will be ignored by the simulator.

Table 4.1: Alphabetic List of GLOBAL Section Keywords

A more detailed description of the keywords is presented in the following sections.

4.3 KEYWORD DEFINITIONS

4.3.1 COLUMNS – DEFINE INPUT FILE COLUMN MARGINS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The COLUMNS keyword defines the input file column margins; characters outside the margins are ignored by the input parser.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

4.3.2 DEBUG – DEFINE THE DEBUG DATA TO BE PRINTED TO FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the debug data to be written to the debug file (*.DBG). This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

4.3.3 ECHO – ACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns on echoing of all the input files to the print file; note that this keyword is activated by default and can subsequently be switched off by the NOECHO activation keyword.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--         SWITCH OFF ECHOING OF INPUT FILES
--
NOECHO
--
--         INCLUDE SIMULATION GRID WITH SLOPING FAULTS
--
INCLUDE
           './INCLUDE/GRID/IRAP_1005.GRDECL' /
--
--         SWITCH ON ECHOING OF INPUT FILES
--
ECHO
```

The examples deactivates the echoing of the input files, reads in the grid geometry data using the INCLUDE keyword, and then activates the echoing of the input files again.

Note

Especially for the large voluminous data sets in the GRID section, it is good practice to deactivate the echoing of the input files when loading this data to avoid the print output file becoming too large to view in a text editor.

4.3.4 END – DEFINE THE END OF THE INPUT FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword marks the end of the input file and can occur in any section. Any keywords and data after the END keyword are ignored.

There is no data required for this keyword.

Example

```
-- ------------------------------------------------------------------------
-- SCHEDULE SECTION - 2006-01-01
-- ------------------------------------------------------------------------
RPTSCHED
'WELLS=2'    'WELSPECS'    'CPU=2'     'FIP=2'                              /

DATES
 1  JAN   2006  /
/

RPTSCHED
'NOTHING'                                                                 /

DATES
 1  APR   2006  /
 1  JLY   2006  /
 1  OCT   2006  /
/
ECHO
--
-- ************************************************************************
-- END OF FILE
-- ************************************************************************
END
-- ------------------------------------------------------------------------
-- SCHEDULE SECTION - 2007-01-01
-- ------------------------------------------------------------------------
RPTSCHED
'WELLS=2'    'WELSPECS'    'CPU=2'     'FIP=2'                              /

DATES
 1  JAN   2007  /
/
```

In the above example OPM Flow will process the data up to October 1, 2006 only, and then start to run the simulation. All keywords after the END file keyword will not be read or processed.

4.3.5 ENDINC – DEFINE THE END OF AN INCLUDE FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword marks the end of an include file specified on the INCLUDE keyword. When the ENDINC keyword is encountered in the INCLUDE file, input data is read from the next keyword in the current file. Any keywords and data after the ENDINC keyword in the INCLUDE file are ignored.

There is no data required for this keyword.

Example

```
-- ------------------------------------------------------------------------
-- SCHEDULE SECTION - 2006-01-01
-- ------------------------------------------------------------------------
RPTSCHED
'WELLS=2'    'WELSPECS'    'CPU=2'     'FIP=2'                              /

DATES
 1  JAN   2006  /
/

RPTSCHED
'NOTHING'                                                                 /

DATES
 1  APR   2006  /
 1  JLY   2006  /
 1  OCT   2006  /
/
ECHO
--
-- ************************************************************************
-- END OF INCLUDE FILE PROCESSING
-- ************************************************************************
ENDINC
-- ------------------------------------------------------------------------
-- SCHEDULE SECTION - 2007-01-01
-- ------------------------------------------------------------------------
RPTSCHED
'WELLS=2'    'WELSPECS'    'CPU=2'     'FIP=2'                              /

DATES
 1  JAN   2007  /
/
```

In the above example OPM Flow will process the data up to October 1, 2006 only, and return control to the file that called the INCLUDE keyword, and then continue processing the input files. All keywords after the ENDINC keyword in the INCLUDE FILE will not be read or processed.

4.3.6 ENDSKIP – DEACTIVATE SKIPPING OF KEYWORDS AND INPUT DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns off skipping of keywords that was activated by the SKIP, SKIP100, or SKIP300 keywords. Note that for each SKIP keyword activated there must be a corresponding ENDSKIP keyword.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--        SWITCH ON SKIPPING OF KEYWORDS AND DATA
--
SKIP
--
--        INCLUDE SIMULATION GRID WITH SLOPING FAULTS
--
INCLUDE
          './INCLUDE/GRID/IRAP_1005.GRDECL' /
--
--        SWITCH ON READING OF KEYWORDS AND DATA
--
ENDSKIP
```

The example skips reading of the of the grid geometry data using the INCLUDE keyword, and then reverts back to reading the input files again.

4.3.7 EXTRAPMS – ACTIVATE EXTRAPOLATION WARNING MESSAGES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The EXTRAPMS keyword activates extrapolation warning messages for when OPM Flow extrapolates the PVT or VFP tables. Frequent extrapolation warning messages should be investigated and resolved as this would indicate possible incorrect data and may result in the simulator extrapolating to unrealistic values.

No.	Name	Description	Default
1	EXTRAP	Defines a single integer that activates the extrapolation warning message options for PVT and VFP tables. EXTRAP can have the following values: 1) 0 – No warning messages are give (the default). 2) 1 – PVT table extrapolation warnings are printed. 3) 2 – VFP table extrapolation warnings are printed. 4) 3 – PVT and VFP table extrapolation warnings are printed. 5) 4 - PVT and VFP table extrapolation warnings are printed with additional information.	0
Notes: 1) In addition extrapolation warnings will also be given for Rs and Rv if options (1), (3), and (4) are requested. 2) The keyword is terminated by a "/".			

Table 4.2: EXTRAPMS Keyword Description

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--       ACTIVATE EXTRAPOLATION MESSAGES
--
EXTRAPMS
         2                                                                  /
```

The above example activates the default the VFP table extrapolation warnings option.

4.3.8 FORMFEED – DEFINED THE PRINT FILE FORM-FEED CHARACTER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FORMFEED keyword defines the form-feed character, or carriage control character, for the output print (*.PRT) run summary (*.RSM) files. The keyword should be place at the very top of the input file.

No.	Name	Description	Default
1	FORMFEED	Defines a single integer that defines the carriage control character activates, and should be set to: 1) 1 – Standard FORTRAN (the default). 2) 2 – Form-feed character ASCII(12) 3) 3 – None.	0
Notes: 1) The keyword is terminated by a "/".			

Table 4.3: FORMFEED Keyword Description

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE EXTRAPOLATION MESSAGES
--
FORMFEED
         3                                                                  /
```

The above example sets the carriage return character to no form-feed character.

4.3.9 INCLUDE – LOAD ANOTHER DATA FILE AT THE CURRENT POSITION

Description

The INCLUDE keyword informs OPM Flow to continue reading input data from the specified INCLUDE file. When the end of the INCLUDE file is reached, or the ENDINC keyword is encountered in the included file, input data is read from the next keyword in the current file. Although INCLUDE files can be nested, that is INCLUDE files within INCLUDE files etc., in practice this should be avoided due to the complexity of tracking the files.

No.	Name	Description	Default
1	FILENAME	A character string enclosed in quotes that defines a file to read in and be processed by OPM Flow.	None
Notes: 1) The keyword is terminated by a "/".			

Table 4.4: INCLUDE Keyword Description

Examples

The first example shown below loads the grid file from the same directory as the data file.

```
--
--       LOAD INCLUDE FILE
--
INCLUDE
         'NOR-OPM-A00-GRID.inc'  /
```

The next example loads the same file one directory above from where the data file is located.

```
--
--       LOAD INCLUDE FILE
--
INCLUDE
         '../NOR-OPM-A00-FAULTS.inc'  /
```

The final example loads the same file from a separate include directory found in the parent directory relative to where the data file is located.

```
--
--       LOAD INCLUDE FILE
--
INCLUDE
         '../INCLUDE/NOR-OPM-A00-FAULTS.inc'  /
```

4.3.10 MESSAGE – OUTPUT USER MESSAGE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MESSAGE keyword outputs a user message to the terminal, as well as to the print (*.PRT) and debug (*.DBG) files. Note this is different to the MESSAGES keyword, that defines OPM Flows message print limits and stop limits generated by the simulator.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

4.3.11 MESSAGES – DEFINE MESSAGE PRINT LIMITS AND STOP LIMITS

Description

The MESSAGES keyword defines the print and stops levels for various messages. The "print limits" set the maximum number of messages that will be printed, after which no more messages will be printed and the "stop limits" terminate the run when these limits are exceeded. There are six levels of message that increase in severity from informative all the way to programming errors, as outlined in Table 4.5.

No.	Name	Description	Default
1	PRTSMESG	An integer defining the maximum number of MESSAGE type messages to be printed after which this type of message stops printing.	1,000,000
2	PRTSCOMT	An integer defining the maximum number of COMMENT type messages be printed after which this type of message stops printing.	1,000,000
3	PRTSWARN	An integer defining the maximum number of WARNING type messages be printed after which this type of message stops printing.	10,000
4	PRTSPROB	An integer defining the maximum number of PROBLEM type messages to be printed after which this type of message stops printing.	100
5	PRTSERRS	An integer defining the maximum number of ERROR type messages to be printed after which this type of message stops printing.	100
6	PRTSBUGS	An integer defining the maximum number of BUG type messages to be printed after which this type of message stops printing.	100
7	STOPMESG	An integer defining the maximum number of MESSAGE type messages to be printed after which OPM Flow terminates the run. Not used by OPM Flow.	1,000,000
8	STOPCOMT	An integer defining the maximum number of COMMENT type messages to be printed after which OPM Flow terminates the run. Not used by OPM Flow.	1,000,000
9	STOPWARN	An integer defining the maximum number of WARNING type messages to be printed after which OPM Flow terminates the run. Not used by OPM Flow.	10,000
10	STOPPROB	An integer defining the maximum number of PROBLEM type messages to be printed after which OPM Flow terminates the run. Not used by OPM Flow.	100
11	STOPERRS	An integer defining the maximum number of ERROR type messages to be printed after which OPM Flow terminates the run. Not used by OPM Flow.	10
12	STOPBUGS	An integer defining the maximum number of BUG type messages to be printed after which OPM Flow terminates the run. Not used by OPM Flow.	1

No.	Name	Description	Default
13	PRTGRPMS	An integer defining the maximum number of GROUP MESSAGE type messages to be printed after which this type of message stops printing. Not used by OPM Flow.	10

Notes:

1) MESSAGE type messages are informative messages.
2) COMMENT type messages are probably not data errors.
3) WARNING type message are possible data errors and should be investigated.
4) PROBLEM type errors messages are associated with numerical problems.
5) ERROR type messages are errors that need to be fixed before the simulator can run the input deck.
6) BUG type of messages are potential programming errors.
7) The keyword is terminated by a "/".

Table 4.5: MESSAGES Keyword Description

Example

```
--
--       MESS  COMMT WARN  PROBL ERROR BUG   MESS COMMT WARN  PROBL ERROR BUG
--       LIMIT LIMIT LIMIT LIMIT LIMIT LIMIT STOP STOP  STOP  STOP  STOP  STOP
MESSAGES
         1*    1*    1*    1500  1*    1*    1*   1*    1*    1000  1*    1*   /
```

The above example sets the PROBLEM type message print limit to 1,500 and the stop limit to 1,000.

4.3.12 NOECHO – DEACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns off echoing of all the input files to the print file. Note by default echoing of the inputs files is active. but can subsequently be switched off by the NOECHO activation keyword.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--        SWITCH OFF ECHOING OF INPUT FILES
--
NOECHO
--
--        INCLUDE SIMULATION GRID WITH SLOPING FAULTS
--
INCLUDE
          './INCLUDE/GRID/IRAP_1005.GRDECL' /
--
--        SWITCH ON ECHOING OF INPUT FILES
--
ECHO
```

The example deactivates the echoing of the input files, reads in the grid geometry data using the INCLUDE keyword, and then activates the echoing of the input files again.

Note

Especially for the large voluminous data sets in the GRID section, it is good practice to deactivate the echoing of the input files when loading this data to avoid the print output file becoming too large to view in a text editor.

4.3.13 NOWARN – DEACTIVATE WARNING MESSAGES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns off warning messages to be printed to the print file; note that this keyword is deactivated by default and can subsequently be switched off by the WARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN.

It is recommended that WARN should always be used and action taken if necessary. For subsequent runs, the warning messages can be turned off.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--      SWITCH OFF WARNING MESSAGES
NOWARN
--
--      INCLUDE SIMULATION GRID WITH SLOPING FAULTS
--
INCLUDE
     './INCLUDE/GRID/IRAP_1005.GRDECL' /
--
--      SWITCH ON WARNING MESSAGES
--
WARN
```

The example deactivates the warning messages before reading the grid geometry data using the INCLUDE keyword, and then activates the warning messages after reading the INCLUDE file.

4.3.14 SKIP – ACTIVATE SKIPPING OF ALL KEYWORDS AND INPUT DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SKIP keyword turns on skipping of keywords until the ENDSKIP activation keyword is encountered. All keywords and between the SKIP and ENDSKIP keywords are ignored by OPM Flow. See also the SKIP100 and SKIP300 keywords that skip only the black-oil and compositional keywords, respectively.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--        SWITCH ON SKIPPING OF ALL KEYWORDS AND DATA
--
SKIP
--
--        INCLUDE SIMULATION GRID WITH SLOPING FAULTS
--
INCLUDE
          './INCLUDE/GRID/IRAP_1005.GRDECL' /
--
--        SWITCH ON READING OF ALL KEYWORDS AND DATA
--
ENDSKIP
```

The example skips reading of the of the grid geometry data using the INCLUDE keyword, and then reverts back to reading the input files again.

4.3.15 SKIP100 – ACTIVATE SKIPPING OF BLACK-OIL KEYWORDS AND INPUT DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword turns on skipping of black-oil keywords until the ENDSKIP activation keyword is encountered. All black-oil keywords between the SKIP100 and ENDSKIP keywords are ignored by OPM Flow. See also the SKIP and SKIP300 keywords that skip all and only the compositional keywords, respectively. There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--       SWITCH ON SKIPPING OF BLACK-OIL KEYWORDS AND DATA
--
SKIP100
--
--       INCLUDE BLACK-OIL PVT DATA
--
INCLUDE
         './INCLUDE/'BLACK-OIL-PVT'         /
--
--       INCLUDE COMPOSITIONAL PVT DATA
--
INCLUDE
         './INCLUDE/'COMPOSITION-PVT-EOS'   /
--
--       SWITCH ON READING OF ALL KEYWORDS AND DATA
--
ENDSKIP
--
--       WATER PVT TABLE
--
PVTW
--       REF PRES  BW        CW        VISC     VISC
--       PSIA      RB/STB    1/PSIA    CPOISE   GRAD
--       --------  ------    -------   ------   ------
          4840.0    1.019     2.7E-6    0.370    1*         / WATER DATA REGION 1
--
--       OIL      WAT        GAS
--       DENSITY  DENSITY    DENSITY
--       -------  -------    -------
DENSITY
          39.0     62.37     0.04520                       / PVT DATA REGION 1
--       ROCK COMPRESSIBILITY
--
--       REF PRES  CF
--       PSIA      1/PSIA
--       --------  -------
ROCK
          3966.9   5.0E-06                                 / ROCK COMPRESSIBILITY
```

The example skips reading of the of the 'BLACK-OIL-PVT' data set and reads the 'COMPOSITION-PVT-EOS' file using the INCLUDE keyword, before proceeding to revert back to reading the input files again.

4.3.16 SKIP300 – ACTIVATE SKIPPING OF "COMPOSITIONAL" KEYWORDS AND INPUT DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns on skipping of "compositional" keywords until the ENDSKIP activation keyword is encountered. All "compositional" keywords between the SKIP300 and ENDSKIP keywords are ignored by OPM Flow. See also the SKIP and SKIP100 keywords that skip all and only the black-oil keywords, respectively. There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--       SWITCH ON SKIPPING OF E300 KEYWORDS AND DATA
--
SKIP300
--
--       INCLUDE BLACK-OIL PVT DATA
INCLUDE
         './INCLUDE/'BLACK-OIL-PVT'         /
--
--       INCLUDE COMPOSITIONAL PVT DATA
--
INCLUDE
         './INCLUDE/'COMPOSITION-PVT-EOS'   /
--
--       SWITCH ON READING OF KEYWORDS AND DATA
--
ENDSKIP
--
--       WATER PVT TABLE
--
PVTW
--       REF PRES  BW        CW        VISC     VISC
--       PSIA      RB/STB    1/PSIA    CPOISE   GRAD
--       --------  ------    -------   ------   ------
          4840.0    1.019     2.7E-6    0.370    1*          / WATER DATA REGION 1

--
--       OIL      WAT        GAS
--       DENSITY  DENSITY    DENSITY
--       -------  -------    -------
DENSITY
          39.0     62.37     0.04520                        / PVT DATA REGION 1

--       ROCK COMPRESSIBILITY
--
--       REF PRES  CF
--       PSIA      1/PSIA
--       --------  -------
ROCK
          3966.9   5.0E-06                                  / ROCK COMPRESSIBILITY
```

The example reads the 'BLACK-OIL-PVT' file using the INCLUDE keyword, then skips reading of the 'COMPOSITION-PVT-EOS" data set, before proceeding to revert back to reading the input files again.

4.3.17 WARN – ACTIVATE WARNING MESSAGES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns on warning messages to be printed to the print file (*.PRT); note that this keyword is activated by default and can subsequently be switched off by the NOWARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN. OPM Flow always prints error messages.

It is recommended that WARN should always be used and action taken if necessary for the initial runs, once the run has been "cleaned up" the warning messages can be turned off.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--        SWITCH OFF WARNING MESSAGES
--
NOWARN

--
--        INCLUDE SIMULATION GRID WITH SLOPING FAULTS
--
INCLUDE
          './INCLUDE/GRID/IRAP_1005.GRDECL' /

--
--        SWITCH ON WARNING MESSAGES
--
WARN
```

The example deactivates the warning messages before reading the grid geometry data using the INCLUDE keyword, and then activates the warning messages after reading the INCLUDE file.

CHAPTER 5: RUNSPEC SECTION

5.1 INTRODUCTION

This is the first section in the OPM Flow input file and defines the key parameters for the simulator including the dimensions of the model, phases present in the model (oil, gas and water for example), number of tables for a given property and the maximum number of rows for each table, the maximum number of groups, wells and well completions, as well as various options to be invoked by the simulator.

The section is defined by the RUNSPEC keyword and is terminated by the GRID keyword.

Keywords associated with the RUNSPEC section are either Activation type keywords to switch on a feature or declare a phase, or a Vector (Row Vector) type of keyword that declares various options or array dimensions. For example, the SATOPTS keyword that activates relative permeability assignment options, or the WELLDIMS keyword that defines the maximum number of wells, completions per well, and maximum number of groups etc. for the run. The keywords can be in any order, but the values entered impact the data the simulator expects in subsequent sections. So for example if the VAPOIL keyword has been invoked to declare that the vaporized oil phase (condensate) in wet gas[63] is present in the run, then the simulator expects the PVTG keyword in the PROPS section to define the wet gas PVT properties. If the PVDG keyword (dry gas[64] PVT data set), has been entered instead in the PROPS section, then the simulator will report this as an error when it reads the PVDG keyword or after processing the PROPS section.

Note that in some instances the numerical values entered need to be the actual values, as per the DIMENS keyword, or maximum values, for example the previously mentioned WELLDIMS keyword. If the requirement for the keyword is for the actual value and an incorrect value has been entered then this may or may not be directly trapped by the simulator, and may result in numerous error message associated with the data instead. Thus, if the error reporting messages in a given section are associated with data that is required to be declared via a RUNSPEC keyword, one should also verify that the RUNSPEC keyword has been correctly defined with the associated problematic data error messages. This is particularly true for the TABDIMS keyword in the RUNSPEC section where some of the variables are defined as the actual number of tables, whereas the length of the tables are a maximum value. To be clear, if NTSFUN on the TABDIMS keyword has been set to five, then there must be exactly five sets of relative permeability data entered in the PROPS section, otherwise data input errors will occur.

5.2 DATA REQUIREMENTS

Table 5.1 outlines the minimum set of keywords required by OPM Flow in order for the simulator to successfully parse the RUNSPEC section.

No.	RUNSPEC Keyword	Description	Section Applied
1	TITLE	*TITLE – Define the Title for the Input Deck* - this is printed on most reports routed to the print file.	RUNSPEC
2	DIMENS	*DIMENS – Define the Dimensions of the Model* - the values entered must be the exact dimensions of the grid, otherwise the simulator will report errors.	GRID

[63] *Natural gas that contains significant heavy hydrocarbons such as propane, butane and other liquid hydrocarbons is known as wet gas or rich gas.*

[64] *Natural gas that occurs in the absence of condensate or liquid hydrocarbons, or gas that had condensable hydrocarbons removed, is called dry gas. It is primarily methane with some intermediates*

No.	RUNSPEC Keyword	Description	Section Applied
3	OIL, DISGAS, GAS, VAPOIL, and/or WATER	*OIL – Activate the Oil Phase in the Model* *DISGAS – Activate the Dissolved Gas Phase in the Model* *GAS – Activate the Gas Phase in the Model* *VAPOIL – Activate the Vaporized Oil in Wet Gas Phase in the Model* *WATER – Activate the Water Phase in the Model* Only the phases present in the run should be declared, so for a dry gas run then only GAS and WATER keywords should be declared, since water is always present in hydrocarbon accumulations.	PROPS
4	FIELD, LAB, or METRIC	*FIELD – Activate the Oil Field System of Units for the Model* *LAB - Activate the Laboratory System of Units for the Model* *METRIC – Activate the Metric System of Units for the Model* States the system of units to be used for the input deck.	ALL
5	WELLDIMS	*WELLDIMS – Define the Wells and Group Dimensions* Sets the well and group dimensions etc.	SCHEDULE
Notes: 1) This limited input for the RUNSPEC section is never used in practice, as real full field models are more complicated.			

Table 5.1: Minimum Set of RUNSPEC Keywords Required by OPM Flow

If the minimum set of RUNSPEC keywords is only entered, then the default values of the missing keywords will apply. This means for example only one set of PVT, relative permeability tables, and one equilibrium region will be assumed by the simulator.

A complete list of RUNSPEC keywords in alphabetic order is shown in Table 5.2 together with a generalized Topic column that classifies the functionality of the keyword. Note that not all keywords and features listed in Table 5.2 are implemented in OPM Flow. Cells not colored in the No. column indicate the keyword is supported, cells colored gray indicate that the keyword is not applicable, and finally, cells colored in orange indicate keywords that are not supported by OPM Flow.

No.	RUNSPEC Keyword	Description	Topic
1	ACTDIMS	*ACTDIMS – ACTION Keyword Dimensions*.	Action
2	ACTPARAM	*ACTPARAM – Define Action Facility Target and Tolerance Parameters*.	Action
3	AITS	*AITS – Activate Intelligent Time Stepping*.	Numeric
4	AITSOFF	*AITSOFF – Deactivate Intelligent Time Stepping*.	Numeric
5	ALKALINE	*ALKALINE – Activate the Alkaline Phase and Model*.	Alkaline
6	API	*API – Activate API Tracking*.	API
7	AQUDIMS	*AQUDIMS – Define Aquifer Dimensions*.	Aquifer

No.	RUNSPEC Keyword	Description	Topic
8	AUTOREF	*AUTOREF - Define Auto Refinement Options*.	LGR
9	BIGMODEL	*BIGMODEL – Activate Big Model Option (Retired)*.	N/A
10	BLACKOIL	*BLACKOIL – Activate Black-Oil Phases*.	Phases
11	BPARA	*BPARA – Activate Block Parallel License*.	N/A
12	BPIDIMS	*BPIDIMS – Define the Dimensions of the Interpolated Block Quantities*.	Output
13	BRINE	*BRINE – Activate Brine Tracking Option*.	Brine
14	CART	*CART – Activate Cartesian Geometry*. This the default grid type that is normally not required to be entered.	Input
15	CBMOPTS	*CBMOPTS – Define Coal Bed Methane Options*.	CBM
16	CO2STORE	*CO2STORE – Activate the CO2 Storage Model*. This is an OPM Flow implementation that is different to the commercial simulator, the keyword is a compositional keyword in the commercial simulator but has been implemented in OPM Flow's black-oil model. The keyword actives the carbon dioxide storage model for the run to account for both carbon dioxide and water phase solubility the simulators CO2-Brine PVT model.	Phases
17	COAL	*COAL – Activate the Coal Phase (CBM Model)*.	CBM
18	COLUMNS	*COLUMNS – Define Input File Column Margins*.	Input
19	CPR	*CPR – Activate Constrained Pressure Residual ("CPR") Linear Solver*. See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.	Numeric
20	DEBUG	*DEBUG – Define the Debug Data to be Printed to File*.	Output
21	DIFFUSE	*DIFFUSE – Activate Molecular Diffusion Option*.	Diffusion
22	DIMENS	*DIMENS – Define the Dimensions of the Model*. The values entered must be the exact dimensions of the grid, otherwise the simulator will report errors.	Input
23	DISGAS	*DISGAS – Activate the Dissolved Gas Phase in the Model*.	Phases
24	DISGASW	*DISGASW – Activate Dissolved Gas in the Water Phase in the Model* This is an OPM Flow specific keyword that activates dissolved gas in the water phase in the model	Phases
25	DISPDIMS	*DISPDIMS – Define the Maximum Number of Dispersion Tables*.	Dispersion
26	DUALPERM	*DUALPERM – Activate Dual Permeability Model*.	Dual-Porosity

No.	RUNSPEC Keyword	Description	Topic
27	DUALPORO	*DUALPORO – Activate Dual Porosity Model*.	Dual-Porosity
28	DYNRDIMS	*DYNRDIMS – Define Dynamic Region Dimensions*.	Input
29	ECHO	*ECHO – Activate Echoing of User Input Files to the Print File*.	Output
30	ECLMC	*ECLMC – Activate Multi-Component Brine Model*.	Brine
31	END	*END – Define the End of the Input File*.	Input
32	ENDINC	*ENDINC – Define the End of an Include File*.	Input
33	ENDSCALE	*ENDSCALE – Activate Relative Permeability End-Point Scaling Option*.	End-Point
34	ENDSKIP	*ENDSKIP – DeActivate Skipping of Keywords and Input Data*.	Input
35	EQLDIMS	*EQLDIMS – Define the Equilibration Data Dimensions*.	Equilibration
36	EQLOPTS	*EQLOPTS – Activate the Equilibration Options*.	Equilibration
37	EXTRAPMS	*EXTRAPMS – Activate Extrapolation Warning Messages*.	Output
38	FAULTDIM	*FAULTDIM – Define the Number of Fault Segments*.	Input
39	FIELD	*FIELD – Activate the Oil Field System of Units for the Model*.	Input
40	FMTHMD	*FMTHMD – Activate The Format History Match Gradient File Option*.	Output
41	FMTIN	*FMTIN – Activate The Format Input File Option*.	Input
42	FMTOUT	*FMTOUT – Activate The Format Output File Option*.	Output
43	FOAM	*FOAM – Activate the Foam Phase and Model*.	Foam
44	FORMFEED	*FORMFEED – Defined the Print File Form-Feed Character*.	Output
45	FRICTION	*FRICTION – Activate Wellbore Friction Option*.	Well
46	FULLIMP	*FULLIMP – Activate Fully Implicit Solution Option*. See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.	Numeric
47	GAS	*GAS – Activate the Gas Phase in the Model*.	Phases
48	GASFIELD	*GASFIELD – Define Gas Field Operations Options*.	Gas Field
49	GDIMS	*GDIMS – Activate Instantaneous Gradient Option and Define Dimensions* .	Gradient
50	GIMODEL	*GI - Define the Initial Equilibration Gi Values for All Grid Blocks*.	Phases

No.	RUNSPEC Keyword	Description	Topic
51	GRAVDR	*GRAVDR – Activate Gravity Drainage and Imbibition for Dual Porosity Model*.	Dual-Porosity
52	GRAVDRB	*GRAVDRB - Activate Vertical Discretized Gravity Drainage and Imbibition for Dual Porosity Model* .	Dual-Porosity
53	GRAVDRM	*GRAVDRM - Activate Alternative Gravity Drainage and Imbibition for Dual Porosity Model*.	Dual-Porosity
54	GRIDOPTS	*GRIDOPTS - Grid Processing Options*.	Input
55	H2STORE	*H2STORE – Activate the H2 Storage Model*. The keyword actives the hydrogen storage model for the run to account for both hydrogen and water phase solubility using the simulator's H2-Brine PVT model.	Phases
56	HMDIMS	*HMDIMS – Define History Match Gradient Parameter Dimensions*.	Gradient
57	HYST	*HYST – Activate the Hysteresis Option (Retired)*. The HYST keyword activates the hysteresis option, the keyword should be avoided and the hysteresis option should be enabled by the HYSTER parameter on the SATOTPS keyword see - *SATOPTS – Activate Relative Permeability Assignment Options* .	Hysteresis
58	IMPES	*IMPES – Activate Implicit Pressure Explicit Saturation Solution Option*. See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.	Numeric
59	IMPLICIT	*IMPLICIT – Activate Fully Implicit Solution Option*. See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.	Numeric
60	INCLUDE	*INCLUDE – Load Another Data File at the Current Position*.	Input
61	INSPEC	*INSPEC – Activate the INSPEC File Option*.	Output
62	LAB	*LAB - Activate the Laboratory System of Units for the Model*.	Input
63	LGR	*LGR – Define Local Grid Refinement Dimensions and Parameters*.	LGR
64	LGRCOPY	*LGRCOPY – Activate Local Grid Refinement Inheritance*.	LGR
65	LICENSES	*LICENSES – Define Required Licenses for Run*.	N/A
66	LIVEOIL	*LIVEOIL – Activate the Live Oil Phase (Oil with Free and Dissolved Gas)*.	Phases
67	LOAD	*LOAD – Load a SAVE File for a Fast Restart*.	Input
68	LOWSALT	*LOWSALT – Activate the Low Salt Brine Phase in the Brine Model*.	Brine

No.	RUNSPEC Keyword	Description	Topic
69	MEMORY	*MEMORY – Define Allocated Memory (Retired)*.	N/A
70	MESSAGE	*MESSAGE – Output User Message*. The MESSAGE keyword outputs a user message to the terminal, as well as to the print (*.PRT) and debug (*.DBG) files.	Output
71	MESSAGES	*MESSAGES – Define Message Print Limits and Stop Limits*. The MESSAGES keyword defines the print and stops levels for various messages.	Output
72	MESSSRVC	*MESSSRVC - Activate or Deactivate Database Message File Output*.	Output
73	METRIC	*METRIC – Activate the Metric System of Units for the Model*.	Input
74	MICP	*MICP – Activate the Microbially Induced Calcite Precipitation Model*. This is an OPM Flow specific keyword that activates the Microbial Induced Calcite Precipitation ("MICP") Model used to investigate CO2 leakage remediation. The module requires that both the MICP and WATER keywords in the RUNSPEC to be active.	MICP
75	MINNPCOL	*MINNPCOL - Define the Minimum Number of Newton Iterations Used to Update Well Targets*. This is an OPM Flow specific keyword that sets the minimum number of Newton iterations, as oppose to the commercial simulator's NUPCOL keyword that defines the maximum number of Newton iterations within a time step, after which well targets are frozen.	Numeric
76	MISCIBLE	*MISCIBLE – Define Miscibility Todd-Longstaff Parameters*.	Miscible
77	MONITOR	*MONITOR – Activate Output of the Monitoring Data and File*.	Output
78	MSGFILE	*MSGFILE – Active or Deactivate Message File Output*.	Output
79	MULTIN	*MULTIN – Activate the Non-Unified Multiple Input File Option*.	Input
80	MULTOUT	*MULTOUT – Activate the Non-Unified Multiple Output File Option*.	Output
81	MULTOUTS	*MULTOUTS – Activate Non-Unified Multiple Summary Output File Option*.	Output
82	MULTREAL	*MULTREAL – Activate Commercial Simulator's Multi-Realization License*.	N/A
83	NETWORK	*NETWORK – Activate the Extended Network Option and Define Parameters*.	Network
84	NINEPOIN	*NINEPOIN – Activate the Nine-Point Discretization Option*.	Numeric
85	NMATRIX	*NMATRIX – Activate the Discretized Matrix Dual Porosity Option*.	Dual-Porosity
86	NNEWTF	*NNEWTF – Activate the Non-Newtonian Fluid Model*.	Numeric

No.	RUNSPEC Keyword	Description	Topic
87	NOCASC	*NOCASC – Activate Linear Solver Tracer Algorithm*. See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.	Tracers
88	NODPPM	*NODPPM – Deactivate Fracture Porosity-Permeability Calculation*	Dual-Porosity
89	NOECHO	*NOECHO – Deactivate Echoing of User Input Files to the Print File*.	
90	NOHYST	*NOHYST - Deactivate the Hysteresis Option*.	Hysteresis
91	NOINSPEC	*NOINSPEC – Deactivate Output of the INIT Index File*.	Output
92	NOMONITO	*NOMONITO – Deactivate Output of the Monitoring Data and File*.	Output
93	NONNC	*NONNC – Deactivate Non-Neighbor Connections*.	Input
94	NORSSPEC	*NORSSPEC – Deactivate Output of the RESTART Index File*.	Output
95	NOSIM	*NOSIM – Activate the No Simulation Mode for Data File Checking*.	Numeric
96	NOWARN	*NOWARN – Deactivate Warning Messages*.	Output
97	NRSOUT	*NRSOUT – Defined Maximum Number of RESTART Elements* .	Output
98	NSTACK	*NSTACK – Define the Stack Length for the Iterative Linear Solver*.	Numeric
99	NUMRES	*NUMRES – Define the Number of Reservoir Grids*. Currently, this should only be set to one in OPM Flow.	Input
100	NUPCOL	*NUPCOL – Define the Maximum Number of Newton Iterations Used to Update Well Targets*.	Numeric
101	OIL	*OIL – Activate the Oil Phase in the Model*.	Phases
102	OPTIONS	*OPTIONS – Activate Various Program Options*.	Options
103	PARALLEL	*PARALLEL – Define Parallel Run Configuration*. The keyword defines the run to use parallel processing and sets the domain decomposition options. See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to run OPM Flow in parallel mode.	Numeric
104	PARTTRAC	*PARTTRAC – Activate and Define Partitioned Tracer Option*.	Tracers
105	PATHS	*PATHS – Define Filename Directory Path Aliases*.	Input
106	PEDIMS	*PEDIMS – Define Petro-Elastic Model Regions and Table Dimensions*.	Petro-Elastic
107	PETOPTS	*PETOPTS – Define Petrel and Generic Simulation File Options*.	Input
108	PIMTDIMS	*PIMTDIMS – Define Well Productivity Scaling Table Dimensions*.	Wells

No.	RUNSPEC Keyword	Description	Topic
109	PINTDIMS	*PINTDIMS – Define Polymer Molecular Weight Model Table Dimensions*. This is an OPM Flow specific keyword for the simulator's Polymer Molecular Weight Transport option that uses the polymer molecular weight in calculating the polymer viscosity, as well as accounting for formation damage due to the water and polymer injection, by adjusting the wellbore skin pressure.	Polymer
110	POLYMER	*POLYMER – Activate the Polymer Phase in the Model*.	Polymer
111	POLYMW	*POLYMW – Activate the Polymer Molecular Weight Transport Option* This is an OPM Flow specific keyword for the simulator's Polymer Molecular Weight Transport option that uses the polymer molecular weight in calculating the polymer viscosity, as well as accounting for formation damage due to the water and polymer injection, by adjusting the wellbore skin pressure.	Polymer
112	PRECSALT	*PRECSALT – Activate the OPM Flow Salt Precipitation Model*. This is an OPM Flow specific keyword for the simulator's Salt Precipitation Model, note that this is an extension to the commercial simulator's Brine Model.	Water Vaporization
113	PSTEADY	*PSTEADY – Activate Pseudo Steady State Flow Calculation Option*.	Numeric
114	RADIAL	*RADIAL – Radial Grid Activation Option*.	Radial
115	REGDIMS	*REGDIMS – Define the Maximum Number of Regions for a Region Array*.	Input
116	RIVRDIMS	*RIVRDIMS – Define the River Dimensions and Associated Data*.	Rivers
117	ROCKCOMP	*ROCKCOMP – Activate Rock Compaction* .	Compaction
118	RPTCPL	*RPTCPL – Activate Couple Simulation Reporting*.	Output
119	RPTHMD	*RPTHMD - Define Well History Match Gradient Reporting Options*.	Gradient
120	RPTRUNSP	*RPTRUNSP – Activate RUNSPEC Reporting*.	Output
121	RSSPEC	*RSSPEC – Activate Output of the RESTART Index File*.	Output
122	RUNSPEC	*RUNSPEC - Define the Start of the RUNSPEC Section of Keywords*	
123	SAMG	*SAMG – Activate Algebraic Multi-Grid Linear Solver*. See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.	Numeric
124	SATOPTS	*SATOPTS – Activate Relative Permeability Assignment Options* .	Input
125	SAVE	*SAVE – Activate Output of a SAVE File for Fast Restarts*.	Output

No.	RUNSPEC Keyword	Description	Topic
126	SCDPDIMS	*SCDPDIMS – Define Scale Deposition and Damage Table Dimensions*.	Scale Deposition
127	SKIP	*SKIP – Activate Skipping of All Keywords and Input Data*.	Input
128	SKIP100	*SKIP100 – Activate Skipping of Black-Oil Keywords and Input Data*.	Input
129	SKIP300	*Error: Reference source not found*.	Input
130	SMRYDIMS	*SMRYDIMS – Define Maximum Number of Summary Vectors to be Written* .	Output
131	SOLVDIMS	*SOLVDIMS – Define PEBI Grid Nested Factorization Solver Dimensions* . See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.	Numeric
132	SOLVENT	*SOLVFRAC – Define the Initial Gas Solvent Fraction for All Grid Blocks*	Solvent
133	SPIDER	*SPIDER – Spider Grid Activation Option*. This is an OPM Flow specific keyword for the simulator's Spider Grid option, that emulates a Radial Grid via corner-point geometry. The option employs the standard GRID section radial grid keywords to construct the grid - see the example in the section on Spider Grids (*Spider Grids*).	Radial
134	START	*START – Simulation Start Date*.	Numeric
135	SURFACT	*SURFACT – Activate the Surfactant Phase in the Model*.	Surfactant
136	SURFACTW	*SURFACTW – Activate the Surfactant Phase with Wettability Changes in the Model*.	Surfactant
137	TABDIMS	*TABDIMS – Define the Number of Tables and the Table Dimensions*.	Input
138	TEMP	*TEMP – Activate the Temperature Modeling Option*. The temperature option (TEMP keyword) and the thermal option (THERMAL keyword) are two separate modeling facilities in the commercial simulator. See *THERMAL– Activate the Thermal Modeling Option* for additional information.	Thermal
139	THERMAL	*THERMAL– Activate the Thermal Modeling Option*. This keyword activates OPM Flow's thermal modeling option. The energy black-oil implementation in OPM Flow is a mixture of the commercial simulators black-oil and the commercial simulator's "compositional thermal" keywords, as well as some OPM Flow specific keywords. See the keyword for further information.	Thermal
140	TITLE	*TITLE – Define the Title for the Input Deck*.	Input
141	TRACERS	*TRACERS – Activate Tracer Options and Set Tracer Array Dimensions*.	Tracers

No.	RUNSPEC Keyword	Description	Topic
142	TRPLPORO	*TRPLPORO – Activate the Triple Porosity Model Option*.	Triple-Porosity
143	UDADIMS	*UDADIMS – Define the Dimensions of the User Defined Arguments*.	Action
144	UDQDIMS	*UDQDIMS – Define the Dimensions of the User Defined UDQ Feature*.	Action
145	UDQPARAM	*UDQPARAM – Define Parameters for the User Defined Quantity Feature*.	Action
146	UDTDIMS	*UDTDIMS – Define the Dimensions of the User Defined Tables*.	Action
147	UNCODHMD	*UNCODHMD – Activate History Match Gradient Unencoded Output*.	Gradient
148	UNIFIN	*UNIFIN – Activate The Unified Input File Option*.	Input
149	UNIFOUT	*UNIFOUT – Activate The Unified Output File Option*.	Output
150	UNIFOUTS	*UNIFOUTS – Activate The Unified Output Summary File Option*.	Output
151	UNIFSAVE	*UNIFSAVE – Activate The Unified Output Save File Option*.	Output
152	VAPOIL	*VAPOIL – Activate the Vaporized Oil in Wet Gas Phase in the Model*	Phases
153	VAPWAT	*VAPWAT – Activate Vaporized Water in the Dry and Wet Gas Phases*. This is an OPM Flow specific keyword for the simulator's Water Vaporization Model that is activated by declaring that vaporized water is present in the run.	Water Vaporization
154	VE	*VE – Activate Vertical Equilibrium Model (Global)*.	Input
155	VFPIDIMS	*VFPIDIMS – Injection Vertical Flow Performance Table Dimensions*.	Well
156	VFPPDIMS	*VFPPDIMS – Production Vertical Flow Performance Table Dimensions*.	Well
157	VISAGE	*VISAGE - Activate External Reservoir Geo-Mechanics VISAGE Option*.	N/A
158	VISCD	*VISCD – Activate Dual Porosity Viscous Displacement Option* .	Dual-Porosity
159	WARN	*WARN – Activate Warning Messages*.	Output
160	WATER	*WATER – Activate the Water Phase in the Model*.	Phases
161	WELLDIMS	*WELLDIMS – Define the Wells and Group Dimensions*.	Well
162	WPOTCALC	*WPOTCALC – Well Potential Calculation Options*.	Well
163	WSEGDIMS	*WSEGDIMS – Define Multi-Segment Well Dimensions*.	Multi-Segment Well

No.	RUNSPEC Keyword	Description	Topic

Notes:

1) Note that not all keywords and features listed above are implemented in OPM Flow. Cells not colored in the No. column indicate the keyword is supported or partially supported by OPM Flow, cells colored gray indicate that the keyword is not applicable, and finally, cells colored in orange indicate keywords that are not supported by OPM Flow and will be ignored by the simulator.
2) For the Topic column the definition of the entries is defined as follows:
   1) **Action:** Keywords associated with the ACTIONX or OPM Flow's Python facility.
   2) **API:** Keywords associated with the API option.
   3) **Brine:** Keywords associated with the BRINE option.
   4) **CBM:** COAL BED METHANE activation and options (not implemented in OPM Flow).
   5) **Diffusion:** DIFFUSION model activation and options.
   6) **Dispersion:** DISPERSION model activation and options.
   7) **Dual-Porosity:** DUAL POROSITY and DUAL PERMEABILITY model activation and parameters.
   8) **End-Point:** END-POINT SCALING activation and options.
   9) **Equilibration** EQUIL section control and options.
   10) **Gas Field:** GAS FIELD model activation, control and options.
   11) **Gradient:** Keywords associated with the GRADIENT option, used in history matching.
   12) **Foam:** FOAM model activation.
   13) **Hysteresis:** HYSTERESIS model.
   14) **Input:** Input control and options.
   15) **LGR:** LOCAL GRID REFINEMENT dimensions and options.
   16) **MICP:** MICROBIAL INDUCED CALCITE PRECIPITATION model activation.
   17) **Multi-Segment**: Multi-Segment well dimensions and options.
   18) **Network:** Activation and options for the NETWORK model.
   19) **Numeric**: Keywords related to the various numeric control and options for the run.
   20) **Output:** Output control and options.
   21) **Phases:** Declarations related to the active phases.
   22) **Scale Deposition:** Scale and BRINE options.
   23) **Solvent:** SOLVENT phase options
   24) **Surfactant**: SURFACTANT phase activation and options.
   25) **Thermal:** THERMAL model activation and options.
   26) **Tracers:** TRACER model options.
   27) **Triple-Porosity:** TRIPLE POROSITY model option activation.
   28) **Water Vaporization:** WATER VAPORIZATION activation.

Table 5.2:Alphabetic List of RUNSPEC Keywords

Note that a number of keywords can be classified under several topics, so the Topic column should only be used as a general reference guide.

Example

A typical RUNSPEC section using various keywords is shown below and on the next few pages for reference.

```

-- ========================================================================
```

The above example is rather extensive but is not unrealistic in terms of the features being activated and the array size declarations.

Previously on 32-bit systems, array sizes were important to ensure that there was sufficient addressable memory to load the input deck and to be able to run given the memory limitations, this is no longer a concern on modern 64-bit systems like Linux.

5.3 KEYWORD DEFINITIONS

5.3.1 ACTDIMS – ACTION KEYWORD DIMENSIONS

Description

The ACTDIMS keyword defines the maximum number of properties associated with the ACTION keyword. The ACTION keyword allows the user to enter computational logic and calculations to the simulation run based on the how the simulation run is proceeding.

No.	Name	Description	Default
1	MXACTNS	A positive integer value that defines the maximum number of ACTION keywords defined in the input deck.	2
2	MXLINES	A positive integer value that defines the maximum number of lines in an ACTION statement.	50
3	MXCHARS	A positive integer value that defines the maximum characters in an ACTION statement.	80
4	MXSTATMS	A positive integer value that defines the maximum number of conditional statements in the ACTION statement.	3
Notes: 1) The keyword is terminated by a "/".			

Table 5.3:ACTDIMS Keyword Description

Only the ACTIONX keyword and computational logic have been implemented in OPM Flow.

Example

```
--       ACTION    ACTION   ACTION   ACTION
--       MXACTNS   MXLINES  MXCHARS  MXSTATMS
ACTDIMS
         2         50       80       3                                   /
```

The above example defines the default values for the ACTDIMS keyword.

5.3.2 ACTPARAM – DEFINE ACTION FACILITY TARGET AND TOLERANCE PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ACTPARAM keyword defines the maximum target percent value for the ACTION series of keywords and the fractional equality tolerance for determining if two numbers are numerically equal when comparing values using the ACTION series of keywords. The ACTION keyword allows the user to enter computational logic and calculations to the simulation run based on the how the simulation run is proceeding.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	MXTOLS	A positive real value that defines the maximum target percent number for the ACTION series of keywords. The default value of 100 means the target is not applied.			
		percent 100.0	percent 100.0	percent 100.0	Defined
2	MXEQLS	MXEQLS a real positive number greater than zero and less than one that defines the tolerance used to determine if two real values are equal for comparing values in the ACTION series of keywords. Floating-point numbers (as implemented in computers) are never exact, one cannot compare floating point numbers for exact equality. Thus, MXEQLS defines a tolerance. For example, the default value of 1 x 10-4 means that if the difference between two real values is less than 1 x 10-4 then the values are considered equal.			
		fraction 1 x 10-4	fraction 1 x 10-4	fraction 1 x 10-4	Defined
Notes: 1) The keyword is terminated by a "/".					

Table 5.4:ACTPARAM Keyword Description

Although this keyword is read by OPM Flow, the ACTION and UDQ computational logic and calculations have not been fully implemented and therefore this keyword should not be used as it may result in OPM Flow terminating.

Example

```
--
--        ACTION    ACTION
--        MXTOLS    MXEQLS
ACTPARAM
          5.0       1.0E-4                                          /
```

The above example defines the maximum tolerance to be 5% and the equality tolerance to be the default value of 1.0 x 10-4.

5.3.3 AITS – ACTIVATE INTELLIGENT TIME STEPPING

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns on the commercial simulator's intelligent time stepping.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

5.3.4 AITSOFF – DEACTIVATE INTELLIGENT TIME STEPPING

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns off the commercial simulator's intelligent time stepping.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

5.3.5 ALKALINE – ACTIVATE THE ALKALINE PHASE AND MODEL

Description

This keyword indicates that an alkaline phase is present in the model and to activate the Alkaline Model in the run. The keyword will also invoke data input file checking to ensure that all the required Alkaline Model input parameters are defined in the input deck.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ALKALINE PHASE IS PRESENT IN THE RUN
--
ALKALINE
```

The above example declares that the alkaline phase is active in the model to activate Alkaline Model.

5.3.6 API – ACTIVATE API TRACKING

Description

This keyword switches on API tracking so that the various "oil types" are tracked in the model.

In many reservoirs the initial API gravity of oil varies with depth due to the heavy viscous fractions occupying the deepest part of the reservoir whilst the lighter more mobile fractions will occupy the upper part of the reservoir. As a reservoir is depleted the API gravity of oil in a cell will gradually change as the different fluids mix.

In OPM Flow it is possible to define different PVT regions in a reservoir, as in all finite difference formulated simulators, oil moving from one region to another will suddenly assume the properties of that region it has moved to. The fluid type tracking option allows the smooth change of PVT properties in a cell to be simulated by correlating PVT properties against the API gravity of oil.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE THE API TRACKING OPTION
--
API
```

The above example switches on the API tracking facility.

5.3.7 AQUDIMS – DEFINE AQUIFER DIMENSIONS

Description

The AQUDIMS keyword defines the dimensions of the various aquifer property data. The data is normally entered on a single line and is terminated by a "/".

No.	Name	Description	Default
1	MXNAQN	A positive integer value that defines the AQUNUM keyword maximum number of lines associated with this keyword, that is the maximum number of numerical aquifers	1
2	MXNAQC	A positive integer value that defines the AQUCON keyword maximum number of lines of connection data associated with this keyword, that is the maximum number of lines of connection data for numerical aquifers.	1
3	NIFTBL	A positive integer value that defines the AQUTAB keyword maximum number of Carter-Tracy aquifer tables associated with this keyword.	1
4	NRIFTB	A positive integer value that defines the AQUTAB keyword maximum number of rows in the Carter-Tracy aquifer tables associated with this keyword. NRIFTB must not be less than 36 in order to accommodate the default infinite acting Carter-Tracy aquifer influence function.	36
5	NANAQ	A positive integer value that defines the AQUFETP, AQUFLUX and AQUCT maximum number of analytical aquifers defined by these three keywords.	1
6	NCAMAX	A positive integer value that defines the maximum number of cells connected to an analytical aquifer.	1
7	MXNALI	A positive integer value that defines the maximum number of aquifer lists.	0
8	MXAAQL	A positive integer value that defines the maximum number of analytical aquifers in any single aquifer list as defined by (7).	0

Notes:

1) The keyword is terminated by a "/".

Table 5.5:AQUDIMS Keyword Description

Example

```
--
--        AQF      AQF      AQF      AQF      AQF      AQF      AQF      AQF
--        MXAQN    MXNAQC   NIFTBL   NRIFTB   NANAQU   NCAMAX   MXNALI   MXAAQL
AQUDIMS
          1*       1*       1*       1*       1*       1*       1*       1*              /
```

The above example defines the default values for the AQUDIMS keyword.

5.3.8 AUTOREF - DEFINE AUTO REFINEMENT OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The AUTOREF keyword activates the Auto Refinement option and defines the parameters for this feature.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.9 BIGMODEL – ACTIVATE BIG MODEL OPTION (RETIRED)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The original intention in the commercial simulator was to define an optimized memory allocation method to handle large models; this has since become redundant and has been retired in the commercial simulator.

This keyword is ignored by both OPM Flow and the commercial simulator and has no effect on the simulation but is documented here for completeness.

5.3.10 BLACKOIL – ACTIVATE BLACK-OIL PHASES

Description

This keyword switches on the black-oil formulation, and is equivalent to setting the phases present in the model to be oil, vaporized oil, gas, and dissolved gas. Note if water is present in the model this needs to be explicitly stated via the WATER keyword in the RUNSPEC section (see also the LIVEOIL keywords in the RUNSPEC section). The keyword is used by the commercial simulator's compositional THERMAL option to set the phases present in the model.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

The following example activates the black-oil phases in the model.

```
--
--       ACTIVATE BLACK-OIL PHASES
--
BLACKOIL
```

Alternatively one could explicitly declare the phases using the following keywords in the RUNSPEC section.

```
--
--       OIL PHASE IS PRESENT IN THE RUN
--
OIL
--
--       VAPORIZED OIL IN WET GAS IS PRESENT IN THE RUN
--
VAPOIL
--
--       GAS PHASE IS PRESENT IN THE RUN
--
GAS
--
--       DISSOLVED GAS IN LIVE OIL IS PRESENT IN THE RUN
--
DISGAS
```

The above example switches on the black-oil phases in the model.

5.3.11 BPARA – ACTIVATE BLOCK PARALLEL LICENSE

Description

The BPARA keyword activates the block parallel license in the commercial simulator. There is no data required for this keyword; however the keyword should be followed by the PARALLEL keyword in the RUNSPEC section, as illustrated in the example below.

There is no data required for this keyword and there is no terminating "/" for this keyword.

OPM Flow is an open source project and therefore there is no license management of the various implemented options or the number of cores/threads that can be utilized; hence this keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to run OPM Flow in parallel mode.

Example

```
--
--       ACTIVATE BLOCK PARALLEL LICENSE
--
BPARA
--
--       PARALLEL MULTI-CORE OPTIONS
--       NDMAIN     MACHINE TYPE
PARALLEL
           8      DISTRIBUTED                                                /
```

The above example sets the number of domains (or processors) to eight and for the simulation to run in block parallel mode. This has no effect in OPM Flow input decks.

5.3.12 BPIDIMS – DEFINE THE DIMENSIONS OF THE INTERPOLATED BLOCK QUANTITIES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The BPDIMS keyword defines the dimensions of the interpolated grid block quantities for the BPR_X, BHD_X,BHDF_X, BSCN_X and BCTRA_X, etc. variables declared in the SUMMARY section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.13 BRINE – ACTIVATE BRINE TRACKING OPTION

Description

The BRINE keyword activates the standard Brine Tracking model and optionally defines the water phase to have various salinities if the ECLMC keyword in the RUNSPEC section has been used to activate the Multi-Component Brine model, that allows for the water phase to have multiple water salinities. Note that the Multi-Component Brine model is not supported by OPM Flow.

No.	Name	Description	Default
1	SALTS	An optional character vector string that defines the salts to be tracked for when the Multi-Component Brine model has been activated by the ECLMC keyword in the RUNSPEC section. SALTS should be set to one or more of the following salt chemical formulae: Salt Name — Salt Chemical Formulae Sodium Chloride — NaCl Potassium Chloride — KCl Calcium Chloride — $CaCl_2$ Magnesium Chloride — $MgCl_2$ Sodium Carbonate — Na_2CO_3 Potassium Carbonate — K_2CO_3 Calcium Carbonate — $CaCO_3$ Magnesium Carbonate — $MgCO_3$ Sodium Sulfate — Na_2SO_4 Potassium Sulfate — K_2SO_4 Calcium Sulfate — $CaSO_4$ Magnesium Sulfate — $MgSO_4$ Note that the ECLMC option is currently not available in OPM Flow, so only the BRINE keyword without the optional SALT variables should be declared in the input deck.	None

Notes:

1) There is no data required for this keyword if the standard Brine Tracking option is being activated and there should be no terminating "/" in this case. However, if the Multi-Component Brine Tracking option has been invoked by the ECLMC keyword, a list of SALTS must be supplied and in this case.
2) The keyword is terminated by a "/".

Table 5.6: BRINE Keyword Description

See also the PRECSALT and VAPWAT keywords in the RUNSPEC section that activates OPM Flow's Salt Precipitation model, and the PVTWSALT keyword in the PROPS section to define the water properties with respect to salt concentration.

Example

The first example actives the standard Brine model and has no terminating "/".

```
--
--       ACTIVATE STANDARD BRINE MODEL IN THE RUN
--
BRINE
```

The second example illustrates how to activate OPM Flow's Salt Precipitation model.

```
--
--       ACTIVATE STANDARD BRINE MODEL IN THE RUN
--
BRINE
--
--       ACTIVATE THE OPM FLOW SALT PRECIPITATION MODEL (OPM FLOW KEYWORD)
--
PRECSALT
--
--       VAPORIZED WATER IN DRY/WET GAS IS PRESENT IN THE RUN (OPM FLOW KEYWORD)
--
VAPWAT
```

The third and final example activates the Multi-Component brine model with four different salts.

```
--
--       ACTIVATE MULTI-COMPONENT BRINE MODEL
--
ECLMC
--
--       DEFINE WATER PHASE MULTI-COMPONENT BRINE COMPONENTS
--
--       SALT1   SALT2   SALT3   SALT4   SALT5
BRINE
         NACL    CACL2   MGC03   K2CO3                                    /
```

This option is currently not available in OPM Flow.

5.3.14 CART – ACTIVATE CARTESIAN GEOMETRY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

CART activates the Cartesian grid geometry for the main model, as oppose to a radial geometry. This is the default geometry and therefore the keyword does have to be used to activate this type of geometry.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.15 CBMOPTS – DEFINE COAL BED METHANE OPTIONS

Description

This keyword sets the options for the Coal Bed Methane model which is activated via the COAL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.16 CO2STORE – ACTIVATE THE CO2 STORAGE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The CO2STORE keyword activates the carbon dioxide (CO_2) storage model for the run to account for both carbon dioxide and water phase solubility, via the simulator's CO_2-Brine PVT model. This keyword is a compositional keyword in the commercial simulator but has been implemented in OPM Flow's black-oil model.

The CO_2-Brine PVT model computes the PVT properties such as density, viscosity, and enthalpy internally as functions of pressure, temperature, and composition by using analytic correlations and models from the literature rather than by interpolation from tabulated values. These values are transformed to the standard black-oil equivalent PVT tables internally by the simulator. A full description of the underlying PVT models is described by Sandve et al.[65]. This means that the normal PVT keywords like DENSITY, PVTO, PVDG etc. are not required by OPM Flow when this model is activated, and if entered will be ignored by the simulator. Note that the CO_2-Brine PVT properties depend on the temperature and salinity and these must therefore be entered in the PROPS section. The reservoir temperature can be defined using, e.g., the RTEMP keyword. Region based salinity can be provided using the SALINITY keyword.

The CO2STORE keyword must be used together with either: (1) the GAS and WATER keywords (or alternatively the GASWAT keyword), or (2) the GAS and OIL keywords in the RUNSPEC section. It is recommended that the standard method option (1) is used.

The DISGASW keyword in the RUNSPEC section can be used with option (1) to model dissolution of CO_2 in the Brine.

Option (1) has the advantage that it can be used with the VAPWAT and PRECSALT keywords in the RUNSPEC section to model the impact of both vaporization of residual water and salt precipitation in the near wellbore region on injectivity of CO_2 injection wells.

In option (1), the GAS and WATER (or GASWAT) keywords declare that the gas and water phases are present in the model. When the CO2STORE option is used the water phase represents the brine and the gas phase represents CO_2. Note that the input and output keywords need to be consistent with this assumption, e.g., GSF (gas saturation function) and WSF (water saturation function) should be used for the CO_2-Brine relative permeability, etc.

Although, the DISGAS and VAPOIL keywords can be used with option (2) to model CO_2 dissolution and water vaporization, salt precipitation is not supported with option (2).

Option (2) currently has the advantage that it can be used with the DRSDTCON keyword in the SCHEDULE section to control convective dissolution of CO_2 into the in-situ brine. Support for the use of DRSDTCON with option (1) is planned to be added in the next release.

In option (2), the GAS and OIL keywords declare that the gas and oil phases are present in the model. Internally when CO2STORE is used the oil phase refers to the brine and the gas phase to CO_2. Again, the input and output keywords need to be consistent with this assumption, e.g., SGOF (gas-oil relative permeability) is used for the CO_2-Brine relative permeability, FOIP (Field Oil-In-Place) shows the total amount of brine in the reservoir, etc.

There is no data required for this keyword and there is no terminating "/" for this keyword.

[65] *Tor Harald Sandve1, Sarah E. Gasda, Atgeirr Rasmussen, and Alf Birger Rustad. Convective dissolution in field scale CO_2 storage simulation using the OPM Flow simulator. Submitted to TCCS 11 – Trondheim Conference on CO_2 Capture, Transport and Storage Trondheim, Norway – June 21-23, 2021.*

Examples

The first example shows the standard usage of CO2STORE with Option (1) the Gas-Water model (GASWAT). Here we also activate the dissolved gas in water (DISGASW) and vaporized water in gas (VAPWAT) options in the RUNSPEC section.

```
-- ================================================================================
--

Note in order to get the liquid phase mole fractions of CO_2, that is, the mole factions of CO_2 in the water phase (XMFCO2), and the vapor phase mole factions (YMFWAT) to the restart file, one must use the command line parameter enable-opm-rst-file set equal to true.

The second example shows how to use CO2STORE with the alternative option (2). The example below declares that the carbon dioxide storage model is active for the run to account for both carbon dioxide and water phase solubility using OPM Flow's CO_2-Brine PVT model. Option (2) is used where the OIL phase refers to the brine and the GAS phase to CO_2.

```
-- ======================================================================
--
-- RUNSPEC SECTION
--
-- ======================================================================
RUNSPEC
-- ----------------------------------------------------------------------
-- FLUID TYPES AND TRACER OPTIONS
-- ----------------------------------------------------------------------
--
--       ACTIVATE CO2 STORAGE IN THE MODEL (OPM FLOW CO2 STORAGE KEYWORD)
--
CO2STORE
--
--       OIL PHASE IS PRESENT IN THE RUN BUT IS THE BRINE PHASE FOR CO2STORE
--
OIL
--
--       GAS PHASE IS PRESENT IN THE RUN BUT IS THE CO2 PHASE FOR CO2STORE

```

See the DRSDTCON keyword in the SCHEDULE section for further information on this keyword.

5.3.17 COAL – ACTIVATE THE COAL PHASE (CBM MODEL)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The COAL keyword actives the coal phase and the Coal Bed Methane ("CBM") model for the run.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE THE COAL PHASE (CBM MODEL) IN THE MODEL
--
COAL
```

The above example declares that the Coal phase is active in the run and activates the CBM model option.

5.3.18 COLUMNS – DEFINE INPUT FILE COLUMN MARGINS

The COLUMNS keyword defines the input file column margins; characters outside the margins are ignored by the input parser.

See *COLUMNS – Define Input File Column Margins* in the GLOBAL section for a full description.

5.3.19 COMPS – ACTIVATE COMPOSITIONAL MODELING FORMULATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns on the Compositional Modeling Formulation, and declares the maximum number of components in the model. The keyword should only be used if the CO2STORE keyword and either the GASWAT or the GAS and WATER keywords in the RUNSPEC section, have also be activated for the gas-water two component model.

Note

This is an OPM Flow keyword used with OPM Flow's CO2STORE and GASWAT keywords in the RUNSPEC section, and should not be confused with the more general version of the COMPS keyword used in the commercial compositional simulator.

Secondly, although OPM Flow parses the keyword, the simulator currently ignores the data for this keyword.

No.	Name	Description	Default
1	COMPS	A positive integer defining the maximum number of compositional components in the model. Only the default value of two is currently supported by OPM Flow.	2

Notes:

1) The keyword is terminated by a "/".

Table 5.7: COMPS Keyword Description

Example

The following example defines how to define a two component formulation to be used with the CO2STORE and GASWAT options.

```
-- ======================================================================
--
-- RUNSPEC SECTION
--
-- ======================================================================
RUNSPEC

--
--       ACTIVATE CO2 STORAGE IN THE MODEL (OPM FLOW CO2 STORAGE KEYWORD)
--

--
--       ACTIVATE COMPOSITIONAL MODELING FORMULATION (OPM FLOW KEYWORD)
--
COMPS
         2                                                              /
--
--       ACTIVATE GAS-WATER THE MODEL (OPM FLOW KEYWORD)
--
GASWAT
```

5.3.20 CPR – ACTIVATE CONSTRAINED PRESSURE RESIDUAL ("CPR") LINEAR SOLVER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

Turns on the Constrained Pressure Residual ("CPR")[66], [67] and [68] preconditioner linear solver option, and declares how the solver should be applied. The keyword is equivalent to using the OPM Flow command line parameter --linear-solver= "cprw". Note that if the command line has been used, then this will take precedence over the CPR keyword.

No.	Name	Description	Default
1	CPROPTN	A defined character string that determines how the CPR linear solver should be applied, and should be set to one of the following: 1) ORIGINAL: Here the solver is applied for the whole of the simulation. 2) ADAPTIVE: This option applies the more computational demanding CPR linear solver, only in parts of the run that would benefit from its use, for example when linear convergence is challenging. Note that OPM Flow only supports the ORIGINAL option, which is the default value in OPM Flow, whereas the default value in the commercial simulator is ADAPTIVE. .	ORIGINAL
Notes: 1) The keyword is terminated by a "/".			

Table 5.8: CPR Keyword Description

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.

Example

```
--
--       ACTIVATE CONSTRAINED PRESSURE RESIDUAL LINEAR SOLVER FOR THE RUN
--
CPR
/
```

The above example activates the Constrained Pressure Residual preconditioner linear solver using the default option, that is the ORIGINAL option for OPM Flow.

To enable the CPR preconditioner linear solver option using the command line parameter, use:

```
flow --linear-solver="cpr" CASENAME.DATA
```

[66] *Wallis, J. R., Little, T. E., and Nolen, J. S.: "Constrained Residual Acceleration of Conjugate Residual Methods," paper SPE 13536 presented at the SPE Reservoir Simulation Symposium, Dallas, Texas, USA (February 10-13, 1985).*

[67] *R. Scheichl, M. Roland, J. Wendebourg, Decoupling and block preconditioning for sedimentary basin simulations, Computational Geosciences 7 (2003) 295{318.*

[68] *Klemetsdal, Ø.S., Møyner, O. & Lie, KA. Accelerating multiscale simulation of complex geomodels by use of dynamically adapted basis functions. Comput Geosci 24, 459–476 (2020). https://doi.org/10.1007/s10596-019-9827-z.*

which should usually be combined with the -matrix-add-well-contributions=true option, that is:

```
flow --linear-solver=cpr --matrix-add-well-contributions=true CASENAME.DATA
```

However, the new CPRW preconditioner, that includes wells does not need the latter option, so in this instance use:

```
flow --linear-solver=cprw CASENAME.DATA
```

As of this release the CPRW preconditioner, should be considered experimental, and the recommended configuration for running this is:

```
flow --linear-solver=cprw --linear-solver-reduction=0.005 --cpr-reuse-setup=4
     --cpr-reuse-interval=10 CASENAME.DATA
```

See new Rasmussen et al.[69] for further information on the available numerical algorithms available in OPM Flow.

5.3.21 DEBUG – DEFINE THE DEBUG DATA TO BE PRINTED TO FILE

This keyword defines the debug data to be written to the debug file (*.DBG). This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

See *DEBUG – Define the Debug Data to be Printed to File* in the GLOBAL section for a full description.

5.3.22 DIFFUSE – ACTIVATE MOLECULAR DIFFUSION OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFUSE keyword activates OPM Flow's Molecular Diffusion option based on fluid and grid data (Sandve et al.[70]), similar to the commercial simulator. For field-scale simulations diffusion is a sub-grid phenomenon and is typically not explicitly represented in the flow equations. However, for simulations on the laboratory scale diffusion plays a direct role and therefore needs to be explicitly represented in the flow equations. Diffusion coefficients that control the diffusion depend on temperature, pressure, and salinity. In OPM Flow, the diffusion coefficients are computed internally for pure water using McLachlan and Danckwerts[71] and modified to account for salinity using Ratcliff and Holdcroft[72]. The effect of the porous media on the diffusion is modeled using the relation suggested by Millington and Quirk[73]. The coefficients can also be given for each PVT region as an input parameter using the DIFFC keyword in the PROPS section.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Note

The option has been tested in combination with the CO2STORE keyword, but not for the general case at this point.

Example

```
--
--       ACTIVATE MOLECULAR DIFFUSION OPTION
--
DIFFUSE
```

The above example switches on the molecular diffusion facility.

5.3.23 DIMENS – DEFINE THE DIMENSIONS OF THE MODEL

Description

DIMENS defines the dimensions of the model entered as integer vector. The keyword can be used with all grid types.

No.	Name	Description	Default
1	NX	A positive integer value that defines the number of grid blocks in the x direction for Cartesian grids or the number of grid blocks in the r direction for radial grids	None
2	NY	A positive integer value that defines the number of grid blocks in the y direction for Cartesian grids or the number of grid blocks in the theta direction for radial grids.	None
3	NZ	A positive integer value that defines the number of grid blocks in the z direction for both Cartesian and radial grids.	None
Notes: 1) The keyword is terminated by a "/".			

Table 5.9: DIMENS Keyword Description

Note that NX, NY and NZ are not maximum values but the actual size of the grid. OPM Flow applies these parameters when reading in particular data sets. For example if NX, NY, and NZ are set to 10, 10 and 10 respectively, then for the grid property data like PORO. OPM Flow expects to read in 10 x 10 x 10 or 1,000 porosity values for the PORO array. If the number of porosity values is not equal to 1,000 then OPM Flow will produce an error.

Example

```
--
--        MAX      MAX      MAX
--        NDIVIX   NDIVIY   NDIVIZ
DIMENS
          46       112      22                                          /
```

The above example defines the dimensions for the Norne model of 46 cells in the x direction, 112 cells in the y direction and 22 cells in the z direction.

5.3.24 DISGAS – ACTIVATE THE DISSOLVED GAS PHASE IN THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword indicates that dissolved gas is present in live[74] oil in the model and the keyword should only be used if the there is both oil and gas phases in the model. The keyword may be used for oil-water and oil-water-gas input decks that contain the oil and gas phases. The keyword will also invoke data input file checking to ensure that all the required oil and gas phase input parameters are defined in the input deck.

If the oil has a constant and uniform dissolved gas concentration, Gas-Oil Ratio ("GOR"), and if the reservoir pressure never drops below the saturation pressure (bubble point pressure), then the model can be run more efficiently by omitting the GAS and DISGAS keywords from the RUNSPEC section, treating the oil as a dead oil[75], and defining a constant Rs (GOR) value with keyword RSCONST or RSCONSTT in the PROPS section. This results in the model being run with as a dead oil problem with no active gas phase. However, OPM Flow takes into account the constant Rs in the calculations and reporting.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       DISSOLVED GAS IN LIVE OIL IS PRESENT IN THE RUN
--
DISGAS
```

The above example declares that the dissolved gas in the oil phase is active in the model.

[74] *"Live" oil is oil that contains gas in solution, which is normally the case for most conventional oil reservoirs. However, for oil reservoirs classified as heavy oil reservoirs, the in situ dissolved gas may be negligible and oil would then be classified as gas-free oil which is commonly referred to as "dead" oil.*

[75] *"Dead" oil is oil that it contains no dissolved gas or a relatively thick oil or residue that has lost its volatile components.*

5.3.25 DISGASW – ACTIVATE DISSOLVED GAS IN THE WATER PHASE IN THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword indicates that dissolved gas is present in the water phase in the model. The keyword may only be used for gas-water input decks that contain just the gas and the water phases, which must also be declared. The keyword will also invoke data input file checking to ensure that all the required gas and water phase input parameters are defined in the input deck.

Note

This is an OPM Flow specific keyword for the simulator's Dissolved Gas in Water Model that is activated by declaring that this phase is present in the run.

The activation of this phase may be used for modeling the production of gas from the water in gas fields, where gas has dissolved into the in situ water phase. Although this is always the case, the volumes are usually insignificant compared with the volumes in the hydrocarbon zones, and therefore in nearly all cases the dissolved gas volumes are usually ignored in terms of resource volumes. For gas fields, the interest is normally the amount of water in the gas phase, as this influences the liquid loading rate as the water is liberated from the gas as the fluid transverses up the wellbore.

The second, and primary, application of this black-oil formulation is for CO_2 storage, where injection of CO_2 injection is being conducted in either depleted gas fields or in water filled aquifer zones. Activating the dissolved gas in the water phase under these circumstances will allow the CO_2 to dissolve into the water phase based on the entered PVT properties in the PROPS section. In this case the CO2STORE keyword in the RUNSPEC section should also be present in the deck.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--        GAS PHASE IS PRESENT IN THE RUN
--
GAS
--
--        WATER PHASE IS PRESENT IN THE RUN
--
WATER
--
--        DISSOLVED GAS IN WATER IS PRESENT IN THE RUN (OPM FLOW KEYWORD)
--
DISGASW
--
--        ACTIVATE CO2 STORAGE IN THE MODEL (OPM FLOW CO2 STORAGE KEYWORD)
--
CO2STORE
```

The above example declares that the gas and water phases are present, and that the dissolved gas in the water phase is also active in the model, for modeling CO2 storage.

5.3.26 DISPDIMS – DEFINE THE MAXIMUM NUMBER OF DISPERSION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DISPDIMS key defines the maximum number of dispersion tables, and the maximum number of velocity and concentration elements per table.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.27 DUALPERM – ACTIVATE DUAL PERMEABILITY MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DUALPERM keyword activates the Dual Permeability option and the Dual Porosity option for the run. In a dual porosity system flow occurs between the matrix and the fracture only, whereas in a dual permeability system flow also occurs between the matrix grid blocks[76], [77], [78], [79] and [80].

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE DUAL PERMEABILITY MODEL
--
DUALPERM
```

The above example declares that the Dual Permeability option is active for the run.

5.3.28 DUALPORO – ACTIVATE DUAL POROSITY MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DUALPORO keyword activates the Dual Porosity option for the run. In a dual porosity system flow occurs between the matrix and the fracture only, whereas in a dual permeability system flow also occurs between the matrix grid blocks[81], [82], [83], [84] and [85].

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE DUAL POROSITY MODEL
--
DUALPORO
```

The above example declares that the Dual Porosity option is active for the run.

[81] *Warren, J.E. and Root, P.J. 1963. The Behavior of Naturally Fractured Reservoirs. SPE J. 3 (3): 245–255. SPE-426-PA. http://dx.doi.org/10.2118/426-PA.*

5.3.29 DYNRDIMS – DEFINE DYNAMIC REGION DIMENSIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DYNRDIMS keyword defines the dimensions for the parameters used by the Dynamic Regions facility, including the maximum number of dynamic regions. The Dynamic Regions facility allows for property and reporting regions to vary as the run progresses, based on the parameters and logic defined by the DYNAMICR keyword in the SOLUTION and PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.30 ECHO – ACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns on echoing of all the input files to the print file; note that this keyword is activated by default and can subsequently be switched off by the NOECHO activation keyword.

See *ECHO – Activate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

5.3.31 ECLMC – ACTIVATE MULTI-COMPONENT BRINE MODEL

Description

The ECLM keyword activates the Multi-Component Brine model that allows for the water phase to have multiple water salinities. The keyword should be used in conjunction with the BRINE keyword in the RUNSPEC. Both keywords must be specified to activate the Multi-Component Brine model, whereas the BRINE keyword only is required to activate the standard brine tracking model.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

The first example activates the standard Brine Tracking model.

```
--
--       ACTIVATE STANDARD BRINE MODEL
--
BRINE
```

The next example shows the ECLMC and BRINE keywords for when the Multi-Component Brine model is required.

```
--
--       ACTIVATE MULTI-COMPONENT BRINE MODEL
--
ECLMC
--
--       DEFINE WATER PHASE MULTI-COMPONENT BRINE COMPONENTS
--
--       SALT1   SALT2   SALT3   SALT4   SALT5
BRINE
         NACL    CACL2   MGC03                                              /
```

The above example activates the Multi-Component Brine model with three different water salinities.

5.3.32 END – DEFINE THE END OF THE INPUT FILE

This keyword marks the end of the input file and can occur in any section. Any keywords and data after the END keyword are ignored.

See *END – Define the End of the Input File* in the GLOBAL section for a full description.

5.3.33 ENDINC – DEFINE THE END OF AN INCLUDE FILE

This keyword marks the end of an include file specified on the INCLUDE keyword. When the ENDINC keyword is encountered in the INCLUDE file, input data is read from the next keyword in the current file. Any keywords and data after the ENDINC keyword in the INCLUDE file are ignored.

See *ENDINC – Define the End of an Include File* in the GLOBAL section for a full description.

5.3.34 ENDSCALE – ACTIVATE RELATIVE PERMEABILITY END-POINT SCALING OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ENDSCALE keyword activates OPM Flow's relative permeability end-point scaling option. The relative permeability functions are defined using the either the:

1) SWOF, SGOF, SLGOF series of saturation functions, or the
2) SWFN, SGFN, SGWFN, SOF2, SOF3, SOF32D series of functions.

And are allocated to the grid cells via the SATNUM keyword.

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWLX, SWLY and SWLZ instead of SWL etc. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWLX, SWLX-, SWLY, SWLY- SWLZ and SWLZ-, instead of SWL or the SWLX, SWLY and SWLZ set of keywords.

The keyword also defines the number of saturation end-point tables that allows for the re-scaling of the saturation functions to be a function of depth as opposed to being a grid property array. This is accomplished via the ENKRVD and ENPTVD keywords in the PROPS section.

No.	Name	Description	Default
1	DIRECT	A character string that activates or deactivates directional end-point scaling option. If DIRECT is set to NODIR then directional end-point scaling is switched off and the same saturation function is used in the x, y and z directions (unless activated otherwise by the SATOPTS keyword in the RUNSPEC section). In this case the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR and SOGCR saturation grid arrays and the KRG, KRORG, KRORW and KRW relative permeability grid cell arrays should be used to enter the grid block end-point data. If DIRECT is set to DIRECT then directional end-point scaling is switched on and different saturation functions are used in the x, y and z directions (unless activated otherwise by the SATOPTS keyword in the RUNSPEC section). Here the directional form of the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR and SOGCR saturation grid arrays and the KRG, KRORG, KRORW and KRW relative permeability grid cell arrays should be use to enter the grid block end-point data. For example SWLX, SWLY and SWLZ for SWL. Only the default option is supported by OPM Flow.	NODIR

No.	Name	Description	Default
2	IRREVERS	A character string that activates or deactivates non-reversible end-point scaling option. If IRREVERS is set to REVERS then the end-point scaling is set to reversible and results in the same set of end-point arrays being used for flow from the x_l to x_{l+1} direction as for the flow from the x_l to the x_{l-1} for all directions (x, y and z). Here the SWLX, SWLY and SWLZ series of keywords should be used instead of SWL type of keywords. Alternatively, if IRREVERS is set to IRREVERS then the end-point scaling is set to non-reversible and results in different sets of end-point arrays being applied for flow from the x_l to x_{l+1} direction and the x_l to the x_{l-1} direction, for all directions (x, y, z). in this case the SWLX+, SWLX-, SWLY+, SWLY- SWLZ+ and SWLZ- series of keywords should be utilized instead of SWL or the SWLX, SWLY and SWLZ set of keywords. Only the default option is supported by OPM Flow.	REVERS
3	NTENDP	A positive integer that defines the maximum number of saturation end-point depth tables. The end-point depth tables are used to re-scale the saturation tables as a function of depth as opposed to being a grid block property. NTENDP may also be specified on the TABDIMS keyword, and if specified on both here and on the TABDIMS keyword the maximum value of the two is used. Only the default option is supported by OPM Flow.	1
4	NNODES	A positive integer the defines the maximum number entries for saturation end-point depth tables.	20
5	MODE	A positive integer that activates the options for temperature dependent saturation end-point scaling in the commercial compositional simulator. MODE should be defaulted with either 1* or zero, which means that scaling can only be performed by grid block end-point scaling properties or via saturation end-point depth tables.	0

Notes:

1) Note that the IRREVERS option can only be set to IRREVERS if the DIRECT parameter is set equal to DIRECT.
2) The keyword is terminated by a "/".

Table 5.10: ENDSCALE Keyword Description

Example

```
--        DIRC    REVERSE  MAX      MAX
--        SCALE   SCALE    TABLES   NODES
ENDSCALE
          NODIR   REVERS   1*       1*                                    /
```

The above example invokes the end-point scaling option with end-point scaling being non-directional and reversible with the default number of saturation end-point depth tables (one) with 20 entries per table.

5.3.35 ENDSKIP – DEACTIVATE SKIPPING OF KEYWORDS AND INPUT DATA

Turns off skipping of keywords that was activated by the SKIP, SKIP100, or SKIP300 keywords. Note that for each SKIP keyword activated there must be a corresponding ENDSKIP keyword.

See *ENDSKIP – DeActivate Skipping of Keywords and Input Data* in the GLOBAL section for a full description.

5.3.36 EQLDIMS – DEFINE THE EQUILIBRATION DATA DIMENSIONS

Description

The EQLDIMS keyword defines the maximum number of properties associated with equilibrating the model, that is initializing the model. A reservoir grid can be separated into separate regions in order to apply different pressure regimes and/or fluid contacts. Care should be taken that the different regions are not in communication if the pressures or fluid contacts are different for the various regions, as this would lead to an unstable initialization and would also imply errors in the model description as implemented.

No.	Name	Description	Default
1	NTEQUL	A positive integer value that defines the number of equilibration regions entered using the EQLNUM keyword in the REGIONS section and the number of entries associated with the EQUIL keyword in the SOLUTION section.	1
2	NPRSVD	A positive integer value setting the number of pressure versus depth entries used by OPM Flow in determining equilibration parameters. Unless there is a requirement for a very fine equilibration this parameter should be defaulted.	100
3	NDRXVD	A positive integer value that defines the maximum number of depth entries in equilibration property versus depth tables (RSVD, RVVD, PBVD or PDVD etc.) as defined in the SOLUTION section.	20
4	NTTRVD	A positive integer that defines the maximum number of TVDP tables that describe the initial tracer concentration versus depth.	1
5	NSTRVD	A positive integer that defines the maximum number of depth entries in the TVDP tables as described in (4)	20

Notes:

1) NTEQUL is the exact number of entries must be entered on the EQUIL keyword, otherwise OPM Flow will report an error. It is not a maximum number as for the other region arrays.

2) The keyword is terminated by a "/".

Table 5.11: EQLDIMS Keyword Description

It is common that the EQLNUM and FIPNUM arrays are identical so that the fluid in-place reporting matches the equilibration regions. Thus, in order to avoid errors in this case, one should just use one array (say the FIPNUM property array) and use the COPY keyword to generate the EQLNUM array.

Example

```
--
--        MAX     MAX     RSVD    TVDP    TVDP
--        EQLNUM  DEPTH   NODES   TABLE   NODES
EQLDIMS
          9       1*      20      1*      1*                    /
```

The above example defines nine equilibration regions the default values for the remaining parameters on the EQLDIMS keyword.

5.3.37 EQLOPTS – ACTIVATE THE EQUILIBRATION OPTIONS

Description

The EQLOPTS keyword defines the equilibration options by stating the character command to activate an option to be used for initializing the model. Multiple commands may be utilized to activate several equilibration options following the keyword.

No.	Name	Description	Default
1	MOBILE	A character string that activates the mobile fluid critical saturation end point correction. If the MOBILE command is stated then this option is activated. This option is not supported by OPM Flow but would change the results if supported so the simulation will be stopped. Therefore this character string should be omitted.	None
2	QUIESC	A character string that activates the initial quiescence option that modifies the equilibrium calculated phase pressures to ensure that a steady state solution is obtained. This options ensures that there is no flow potential between the grid blocks in a given region, which is the normal case when block-centered equilibration is used by setting BOINIT on the EQUIL keyword to zero in the SOLUTION section. If the QUIESC command is stated then this option is activated. This option is not supported by OPM Flow but would change the results if supported so the simulation will be stopped. Therefore this character string should be omitted.	None
3	THPRES	A character string that activates the inter-region equilibration flow option. This option allows for a threshold pressure variable entered via the THPRES keyword to define a pressure which prevents flow between regions until the THPRES value between regions is exceeded. If the THPRES command is stated then this option is activated.	None
4	IRREVERS	A character string that activates the irreversible inter-region equilibration flow option. This option can only be invoked if the THPRES command has been stated. The option allows for different THPRES values for different directions. If the IRREVERS command is stated then this option is activated. This option is not supported by OPM Flow but would change the results if supported so the simulation will be stopped. Therefore this character string should be omitted.	None

Notes:

1) The keyword is terminated by a "/".

Table 5.12: EQLOPTS Keyword Description

Example

```
--
--       ACTIVATE EQUILIBRATION OPTIONS
--       MOBILE END-POINT(MOBILE) STEADY STATE(QUIESC) THRESHOLD(THPRES)
--       IRREVERSIBLE THRESHOLD(IRREVERS)
EQLOPTS
         'THPRES'   'IRREVERS'                                          /
```

The above example activates the threshold pressure option with different threshold pressure for different directions.

5.3.38 EXTRAPMS – ACTIVATE EXTRAPOLATION WARNING MESSAGES

The EXTRAPMS keyword activates extrapolation warning messages for when OPM Flow extrapolates the PVT or VFP tables. Frequent extrapolation warning messages should be investigated and resolved as this would indicate possible incorrect data and may result in the simulator extrapolating to unrealistic values.

See *EXTRAPMS – Activate Extrapolation Warning Messages* in the GLOBAL section for a full description.

5.3.39 FAULTDIM – DEFINE THE NUMBER OF FAULT SEGMENTS

Description

The FAULTDIM keyword defines the maximum number of records (or segments) that can be entered with the FAULTS keyword. The FAULTS keyword defines the faults in the grid than can be used for setting (or re-setting) transmissibility barriers across the fault planes.

No.	Name	Description	Default
1	MFSEGS	A positive integer value that defines the maximum number of records (segments) for the FAULTS keyword.	0
Notes: 1) The keyword is terminated by a "/".			

Table 5.13: FAULTDIM Keyword Description

Example

```
--
--        FAULT
--        SEGMS
--
FAULTDIM
          10000                                                    /
```

The above example defines the maximum number of records that can be entered using the FAULT keyword to be 10,000 segments.

5.3.40 FIELD – ACTIVATE THE OIL FIELD SYSTEM OF UNITS FOR THE MODEL

Description

This keyword switches on the oil FIELD system of units for the model.

OPM Flow has three sets of units, namely: METRIC, FIELD and LAB and one of these keyword should be invoked in the RUNSPEC section to avoid any ambiguity. Both the simulator input and output units are controlled by including one of the METRIC, FIELD or LAB keywords in the RUNSPEC section of the input file.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       SWITCH ON THE FIELD SYSTEM OF UNITS FOR BOTH INPUT AND OUTPUT
--
FIELD
```

The above example switches on the FIELD system of units for the model.

5.3.41 FMTHMD – ACTIVATE THE FORMAT HISTORY MATCH GRADIENT FILE OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword switches on formatted output for the History Match Gradient output file, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.42 FMTIN – ACTIVATE THE FORMAT INPUT FILE OPTION

Description

This keyword switches on the Format Input Files option for all input files. Similar to the commercial simulator, OPM Flow has various options for reading various input files and writing the resulting OPM Flow output files as described in Table 5.14.

Process	Keyword	Description	Files
Input	FMTIN	A character string that defines the input files to be formatted as ASCII i.e. text files, as oppose to binary files. The input deck file is always of this type. The option relates to the OPM Flow derived files that used as input, for for example when restarting from another case. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTIN	A character string that defines the input files to be non-unified multiple files, as opposed to unified files. In this case, one file is read in per reporting time step, as opposed to all time steps reports being read from one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001
	UNIFIN	A character string that defines the input files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. For this option a single summary file and a single restart file will be read. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY
Output	FMTOUT	A character string that sets all output files to be formatted as ASCII i.e. text files, as opposed to binary files. The *.PRT, *.LOG and *.DBG files are always of this type. The option relates to the OPM Flow output files only. In this case the files will be portable across operating systems, but will also be very large in terms of hard disk space. For this reason it is recommend that the default option is used so that binary files are outputted. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTOUT	A character string that defines the output files to be non-unified multiple files, as opposed to unified files. In this case, one file is written for each reporting time step, as opposed to all time steps reports being written in one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001

Process	Keyword	Description	Files
	UNIFOUT	A character string that defines the output files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. Here a single summary file and a single restart file will be generated, as opposed to one file per report time step. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY

Notes:

1) A binary file is computer-readable but not human-readable. All executable programs are stored in binary files, as are most numeric data files. In contrast, text files are stored in a form (usually ASCII) that is human-readable.
2) For unified files if the run terminates unexpectedly, or there is sufficient disk space, then the last report output is not stored. Their main advantage is that if a number of simulations reside in one directory, their output is organized. There is no limit on the number of reporting steps that a unified file can store.

Table 5.14: FMTIN Keyword Description

There is no data required for this keyword.

See also *OPM FLOW OUTPUT FILE FORMATS* for a more detailed description of the various file types (ASCII or binary) and file structure formats (unified or non-unified formats).

Example

```
--
--       SWITCH ON THE FORMAT INPUT FILES OPTION
--
FMTIN
```

The above example switches on the format input file option.

5.3.43 FMTOUT – ACTIVATE THE FORMAT OUTPUT FILE OPTION

Description

This keyword switches on the Format Output Files option for all output files. Similar to the commercial simulator, OPM Flow has various options for reading various input files and writing the resulting OPM Flow output files as described in Table 5.15.

Process	Keyword	Description	Files
Input	FMTIN	A character string that defines the input files to be formatted as ASCII i.e. text files, as oppose to binary files. The input deck file is always of this type. The option relates to the OPM Flow derived files that used as input, for for example when restarting from another case. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTIN	A character string that defines the input files to be non-unified multiple files, as opposed to unified files. In this case, one file is read in per reporting time step, as opposed to all time steps reports being read from one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001
	UNIFIN	A character string that defines the input files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. For this option a single summary file and a single restart file will be read. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY
Output	FMTOUT	A character string that sets all output files to be formatted as ASCII i.e. text files, as opposed to binary files. The *.PRT, *.LOG and *.DBG files are always of this type. The option relates to the OPM Flow output files only. In this case the files will be portable across operating systems, but will also be very large in terms of hard disk space. For this reason it is recommend that the default option is used so that binary files are outputted. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTOUT	A character string that defines the output files to be non-unified multiple files, as opposed to unified files. In this case, one file is written for each reporting time step, as opposed to all time steps reports being written in one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001

Process	Keyword	Description	Files
	UNIFOUT	A character string that defines the output files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. Here a single summary file and a single restart file will be generated, as opposed to one file per report time step. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY

Notes:

1) A binary file is computer-readable but not human-readable. All executable programs are stored in binary files, as are most numeric data files. In contrast, text files are stored in a form (usually ASCII) that is human-readable.
2) For unified files if the run terminates unexpectedly, or there is sufficient disk space, then the last report output is not stored. Their main advantage is that if a number of simulations reside in one directory, their output is organized. There is no limit on the number of reporting steps that a unified file can store.

Table 5.15: FMOUT Keyword Description

There is no data required for this keyword.

See also *OPM FLOW OUTPUT FILE FORMATS* for a more detailed description of the various file types (ASCII or binary) and file structure formats (unified or non-unified formats).

Example

```
--
--       SWITCH ON THE FORMAT OUTPUT FILES OPTION
--
FMTOUT
```

The above example switches on the format output file option.

5.3.44 FOAM – ACTIVATE THE FOAM PHASE AND MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates the foam phase and modeling option. The keyword will also invoke data input file checking to ensure that all the required foam phase input parameters are defined in the input deck. Note in the commercial simulator the FOAM phase and model can be used in conjunction with the POLYMER and SURFACT phases; this is not the case for OPM Flow. OPM Flow's FOAM phase and model is a standalone implementation and cannot be used in conjunction with either the POLYMER or SURFACT phases.

Foam flooding is an enhanced oil recovery flood process that attempts to control injected gas breakthrough in an oil reservoir by changing the mobility of the injected fluid.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE THE FOAM PHASE IN THE MODEL
--
FOAM
```

The above example declares that the foam phase is active in the model.

5.3.45 FORMFEED – DEFINED THE PRINT FILE FORM-FEED CHARACTER

The FORMFEED keyword defines the form-feed character, or carriage control character, for the output print (*.PRT) run summary (*.RSM) files. The keyword should be place at the very top of the input file.

See *FORMFEED – Defined the Print File Form-Feed Character* in the GLOBAL section for a dull description.

5.3.46 FRICTION – ACTIVATE WELLBORE FRICTION OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FRICTION keyword activates the Wellbore Friction option and defines the maximum number of wellbore friction wells together with the maximum number of well branches.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	MXWELS	A positive integer defining the maximum number of wellbore friction wells for this model.	0
3	MXBRAN	A positive integer defining the maximum number of branches per well. The default value of one implies a standard well with no branches.	1
Notes: 1) The keyword is terminated by a "/".			

Table 5.16: FRICTION Keyword Description

Example

```
--
--       WELL    BRANCH
--       MXWELS  MXBRAN
FRICTION
         5       1                                                    /
```

The above example defines the maximum number of wellbore friction wells to be five and the maximum number of branches set to one, for standard wells.

5.3.47 FULLIMP – ACTIVATE FULLY IMPLICIT SOLUTION OPTION

Description

The FULLIMP keyword activates the Fully Implicit Solution formulation and solution options. OPM Flow uses a different numerical scheme which makes this keyword redundant; hence, OPM Flow ignores this keyword. It is documented here for completeness. The keyword as the same function as the IMPLICIT keyword in the RUNSPEC section.

There is no data required for this keyword and there is no terminating "/" for this keyword.

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.

Example

```
--
--       ACTIVATES THE FULLY IMPLICIT SOLUTION OPTION
--
FULLIMP
```

The above example switches on the fully implicit solution option; however, this has no effect in OPM Flow input decks.

5.3.48 GAS – ACTIVATE THE GAS PHASE IN THE MODEL

Description

This keyword indicate that the gas phase is present in the model and must be used for oil-gas, gas-water, oil-water-gas input decks that contain the gas phase. The keyword will also invoke data input file checking to ensure that all the required gas phase input parameters are defined in the input deck.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--        GAS PHASE IS PRESENT IN THE RUN
--
GAS
```

The above example declares that the gas phase is active in the model.

5.3.49 GASFIELD – DEFINE GAS FIELD OPERATIONS OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The GASFIELD keyword activates and specifies the Gas Field Operations options and determines if extended compressors are present in the run and if the expedited first pass DCQ calculation should be used.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.50 GASWAT – ACTIVATE THE GAS-WATER MODEL FORMULATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates the two-phase Gas-Water model, as such it is equivalent to using both the GAS and WATER keywords in the RUNSPEC section..

Note

This is an OPM Flow keyword, and should not be confused with the more general version of the GASWAT keyword used in the commercial compositional simulator.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
-- ================================================================================
--
-- RUNSPEC SECTION
--
-- ================================================================================
RUNSPEC
--
--       ACTIVATE CO2 STORAGE IN THE MODEL (OPM FLOW CO2 STORAGE KEYWORD)
--
CO2STORE
--
--       ACTIVATE COMPOSITIONAL MODELING FORMULATION (OPM FLOW KEYWORD)
--
COMPS
         2                                                                      /
--
--       ACTIVATE GAS-WATER THE MODEL (OPM FLOW KEYWORD)
--
GASWAT
```

The above example declares that the run should use the Gas-Water model, together with the CO2STORE option, and with two components.

5.3.51 GDIMS – ACTIVATE INSTANTANEOUS GRADIENT OPTION AND DEFINE DIMENSIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The GDIMS keyword activates the Instantaneous Gradient option and defines the maximum dimensions as used by the GWRTWCV keyword in the SCHEDULE section. The Instantaneous Gradient option calculates derivatives of solution quantities at the current time step with respect to variations in the variables at the current time step. This is different to Gradient option that calculates the derivatives of solution quantities at the current time step with respect to variations in the variables at the initial time step, that is a time equal to zero. Consequently, the Instantaneous Gradient option can be switched on and off by the GUPFREQ keyword in the SCHEDULE section, whereas the Gradient option cannot.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.52 GIMODEL – ACTIVATE GI PSEUDO COMPOSITIONAL OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, GIMODEL, activates the Gi Pseudo Compositional option for gas condensate and volatile oil fluids.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

The accuracy of gas condensate and volatile oil modeling using a black-oil reservoir simulator is now firmly accepted in the industry; both depletion and gas cycling above the saturation point can be modeled and yield an acceptable match compared with compositional simulators. The main deficiency with the existing black-oil formulation is the treatment of gas injection below the saturation point, where the compositional effect of the stripping of liquid components is inversely proportional to their molecular weights, is not considered. This is because the black-oil model assumes that the saturated hydrocarbon fluid properties are only functions of pressure. Thus, when dry gas is injected into a condensate reservoir below the saturation pressure the injected gas continues to re-vaporize liquid at a rate governed only by the cell pressures. Compositional modeling indicate that this not the case.

The GI option attempts to overcome the limitation of the standard black-oil approach by extending the black-oil model using the method of Cook et al.[86] to take into account the fluid property changes occurring during gas injection. This is done by extending the fluid property treatment so that the saturated fluid properties depend on pressure (as per the standard black-oil formulation) and also on an additional parameter which characterizes the compositional changes in the reservoir liquid and vapor phases at constant pressure.

There is no data required for this keyword.

Example

```
--
--       ACTIVATE THE GI PSEUDO COMPOSITIONAL OPTION
--
GIMODEL
```

The above example switches on the Gi Pseudo Compositional option.

[86] *Cook, R. E., Jacoby, R. H., and Ramesh, A. B. "A Beta-type Reservoir Simulator for Approximating Compositional Effects During Gas Injection" paper SPE 4272, Society of Petroleum Engineers Journal (1974) 14, No. 5, 471-481.*

5.3.53 GRAVDR – ACTIVATE GRAVITY DRAINAGE AND IMBIBITION FOR DUAL POROSITY MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword switches on gravity drainage and imbibition modeling between the matrix and the fracture grid blocks in dual porosity and dual permeability runs. Note that either DZMTRX or DZMTRXV keywords in the GRID section should be used to set the matrix vertical dimensions if this option is activated.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE GRAVITY DRAINAGE AND IMBIBITION FOR DUAL POROSITY MODEL
--
GRAVDR
```

The above example switches on the gravity drainage and imbibition option for the run.

5.3.54 GRAVDRB - ACTIVATE VERTICAL DISCRETIZED GRAVITY DRAINAGE AND IMBIBITION FOR DUAL POROSITY MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword switches on vertical discretized gravity drainage and imbibition modeling between the matrix and the fracture grid blocks in dual porosity and dual permeability runs. Note that the geometry of the matrix sub-cells should be set to VERTICAL on the NMATOPS keyword in the GRID section if this option is activated.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE VERTICAL DISCRETIZED GRAVITY DRAINAGE AND IMBIBITION
--
GRAVDRB
```

The above example switches on the vertical discretized gravity drainage and imbibition option for the run.

5.3.55 GRAVDRM - ACTIVATE ALTERNATIVE GRAVITY DRAINAGE AND IMBIBITION FOR DUAL POROSITY MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword switches on the alternative gravity drainage and imbibition modeling between the matrix and the fracture grid blocks in dual porosity and dual permeability runs. Either the GRAVDRM or GRAVDR keywords should be used to activate this standard or alternative type of formulation.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	OPTION1	A defined character string that sets the matrix flow in and out of the matrix block option, and should be set to one of the following: 1) YES: oil flow is bi-directional, that is oil can flow into and out of the matrix block. 2) NO: oil flow is uni-directional, that is oil can flow out of the matrix block.	YES
Notes: 1) The keyword is terminated by a "/".			

Table 5.17: GRAVDRM Keyword Description

Example

```
--
--        ACTIVATE ALTERNATIVE GRAVITY DRAINAGE AND IMBIBITION MODEL
--
--        MATRIX
--        OPTION
GRAVDRM
          YES                                                              /
```

The above example switches on the alternative gravity drainage and imbibition option for the run and sets oil flow to be bi-directional, that is oil can flow into and out of the matrix block.

5.3.56 GRIDOPTS - GRID PROCESSING OPTIONS

Description

GRIDOPTS activates the negative directional dependent transmissibility multipliers option, defines the maximum number of MULTNUM regions and the number of PINCHNUM regions for the model.

No.	Name	Description	Default
1	TRANMULT	A character string that activates the negative directional dependent transmissibility multipliers option by setting TRANMULT to YES. Setting the value to NO switches off this option. OPM Flow uses a positive directional dependent transmissibility formulation to describe the flow between two cells, that is for cell (I, J, K) OPM Flow calculates the x face transmissibility between (I, J, K) and (I +1, J, K) cell face. Modification to the transmissibilities in this case is accomplished by the MULTX, MULTY and MULTZ keywords. Setting TRANMULT to YES invokes the option to use a negative directional dependent multiplier scheme using the MULTX-, MULTY- and MULTZ- keywords. In this case OPM Flow applies the x face transmissibility between (I - 1, J, K) and (I, J, K) cell face when using the MULTX-, MULTY- and MULTZ- keywords. Note that if TRANMULT is defaulted, and there are negative directional dependent multiplier keywords in the input deck, then OPM Flow will continue to process the MULTX-, MULTY- and MULTZ keywords correctly. Whereas, the commercial simulator will terminate with an error.	NO
2	NRMULT	A positive integer value that defines the maximum number of MULTNUM regions for the MULTNUM array. The MULTNUM array is used in the GRID section to define various inter-region transmissibility regions in the model and NRMULT sets the maximum number of regions which is the maximum value of an element in the MULTNUM array. Inter-region MULTNUM transmissibility multipliers can be defined using the MULTREGT and regional pore volumes multipliers can be set using the MULTREGP keyword.	0
3	NRPINC	A positive integer value that defines the maximum number of PINCHNUM regions for the PINCHNUM array. The PINCHNUM array is used in the GRID section to define various regions in the model and NRPINC sets the maximum of regions which is the maximum value of an element in the PINCHNUM array. Each regions criteria for setting the pinch out criteria is set by the PINCHREG keyword.	0
Notes: 1) The keyword is terminated by a "/".			

Table 5.18: GRIDOPTS Keyword Description

See also the MULTNUM, MULTREGP, MULTREGT, PINCHNUM, and PINCHREG keywords.

Example

```
--
--       NEG       MAX      MAX
--       MULTS     MULTNUM PINCHNUM
GRIDOPTS
         NO        9        1*                                                  /
```

The above example switches off the negative directional dependent transmissibility multipliers option and defines the maximum of MULTNUM regions to be nine,. The NRPINC parameter is defaulted which means there the maximum number of PINCHREG regions is zero.

5.3.57 H2STORE – ACTIVATE THE H2 STORAGE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The H2STORE keyword activates the hydrogen (H_2) storage model for the run to account for both hydrogen and water phase solubility. H2STORE is similar to CO2STORE, which activates the carbon dioxide (CO_2) storage model.

The H_2-Brine PVT model computes the PVT properties such as density, viscosity, and enthalpy internally as functions of pressure, temperature, and composition by using analytic correlations and models from the literature rather than by interpolation from tabulated values. These values are transformed to the standard black-oil equivalent PVT tables internally by the simulator. Dissolved hydrogen in brine is modeled using Li et al.[87]. Hydrogen gas density was modeled using Leachman et al.[88]. Other properties are modeled the same way as in CO2STORE but modified for hydrogen-brine (a similar approach was recently reported by Raad et al.[89]). A full description of the underlying PVT models used by CO2STORE is described by Sandve et al.[90]. This means that the normal PVT keywords like DENSITY, PVTO, PVDG etc. are not required by OPM Flow when this model is activated, and if entered will be ignored by the simulator. Note that the H_2-Brine PVT properties depend on the temperature and salinity and these must therefore be entered in the PROPS section. The reservoir temperature can be defined using, e.g., the RTEMP keyword. Region based salinity can be provided using the SALINITY keyword.

The H2STORE keyword must be used with either: (1) the GAS and WATER keywords (or alternatively the GASWAT keyword), or (2) the GAS and OIL keywords in the RUNSPEC section. It is recommended that the standard option (1) is used.

The DISGASW keyword can also be used with option (1) to model dissolution of H_2 in the Brine.

Option (1) has the advantage that it can be used with the VAPWAT and PRECSALT keywords to model the impact of both vaporization of residual water and salt precipitation in the near wellbore region on injectivity of H_2 injection wells.

In option (1), the GAS and WATER (or GASWAT) keywords declare that the gas and water phases are present in the model. When the H2STORE option is used the water phase represents the brine and the gas phase represents H_2. Note that the input and output keywords need to be consistent with this assumption, e.g., GSF (gas saturation function) and WSF (water saturation function) should be used for the H_2-Brine relative permeability, etc.

Although, the DISGAS and VAPOIL keywords can be used with option (2) to model water vaporization and H_2 dissolution, salt precipitation is not currently supported with option (2).

Option (2) currently has the advantage that it can be used with the DRSDTCON keyword to control convective dissolution of H_2 into in-situ brine. Support for the use of DRSDTCON with option (1) is planned to be added in the next release.

[89] *Seyed Mostafa Jafari Raad, Ehsan Ranjbar, Hassan Hassanzadeh, Yuri Leonenko, Hydrogen-brine mixture PVT data for reservoir simulation of hydrogen storage in deep saline aquifers, International Journal of Hydrogen Energy, Volume 48, Issue 2, 2023, Pages 696-708.*

[90] *Tor Harald Sandve, Sarah E. Gasda, Atgeirr Rasmussen, and Alf Birger Rustad. Convective dissolution in field scale CO_2 storage simulation using the OPM Flow simulator. Submitted to TCCS 11 – Trondheim Conference on CO_2 Capture, Transport and Storage Trondheim, Norway – June 21-23, 2021.*

In option (2), the GAS and OIL keywords declare that the gas and oil phases are present in the model. Internally when H2STORE is used the oil phase refers to the brine and the gas phase to H_2. Again, the input and output keywords need to be consistent with this assumption, e.g., SGOF (gas-oil relative permeability) is used for the H_2-Brine relative permeability, FOIP (Field Oil-In-Place) shows the total amount of brine in the reservoir, etc.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Examples

The first example shows the standard useage of H2STORE with Option (1) the Gas-Water model (GASWAT). Here we also activate the dissolved gas in water (DISGASW) and vaporized water in gas (VAPWAT) options.

```

-- ===========================================================================
```

No other data is required to define the fluid and rock properties in the PROPS section as the data is generated from internal analytic correlations and models by the simulator. Finally, note that units for salinity are to the 10^{-3}, thus for metric units we have 10^{-3} x kg-M/kg.

The third part of the example covers initializing the model in the SOLUTION section. Here we use the EQUIL(EQLOPT6) parameter equal to one, to use table number one of the RVWVD keyword, in order to set the vaporized water versus depth distribution for the model.

```

```

Output of the liquid phase mole fractions of H2, that is, the mole factions of H2 in the water phase, and the vapor phase mole factions to the restart file, is only supported for CO2STORE.

The second example shows how to use H2STORE with the alternative option (2). The example below declares that the hydrogen storage model is active for the run to account for both hydrogen and water phase solubility using OPM Flow's H_2-Brine PVT model. Option (2) is used where the OIL phase refers to the brine and the GAS phase to H_2.

```
-- ======================================================================
--
-- RUNSPEC SECTION
--
-- ======================================================================
RUNSPEC
-- ----------------------------------------------------------------------
-- FLUID TYPES AND TRACER OPTIONS

        0.04                                          /
```

See the DRSDTCON keyword in the SCHEDULE section for further information on this keyword.

5.3.58 HMDIMS – DEFINE HISTORY MATCH GRADIENT PARAMETER DIMENSIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, HMDIMS, defines the maximum parameter dimensions for the History Match Gradient option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.59 HYST – ACTIVATE THE HYSTERESIS OPTION (RETIRED)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HYST keyword activates the hysteresis option, the keyword should be avoided and the hysteresis option should be enabled by the HYSER parameter on the SATOTPS keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.60 IMPES – ACTIVATE IMPLICIT PRESSURE EXPLICIT SATURATION SOLUTION OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The IMPES keyword activates the Implicit Pressure Explicit Saturation formulation and solution options, commonly know as IMPES. OPM Flow uses a different numerical scheme which makes this keyword redundant; hence, OPM Flow ignores this keyword. It is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.

Example

```
--
--       ACTIVATE THE IMPES SOLUTION OPTION
--
IMPES
```

The above example switches on the IMPES solution option; however, this has no effect in OPM Flow input decks.

5.3.61 IMPLICIT – ACTIVATE FULLY IMPLICIT SOLUTION OPTION

Description

The IMPLICIT keyword activates the Fully Implicit Solution formulation and solution options. OPM Flow uses a different numerical scheme which makes this keyword redundant; hence, OPM Flow ignores this keyword. It is documented here for completeness. The keyword as the same function as the FULLIMP keyword in the RUNSPEC section.

There is no data required for this keyword and there is no terminating "/" for this keyword.

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.

Example

```
--
--       ACTIVATES THE FULLY IMPLICIT SOLUTION OPTION
--
IMPLICIT
```

The above example switches on the fully implicit solution option; however, this has no effect in OPM Flow input decks.

5.3.62 INCLUDE – LOAD ANOTHER DATA FILE AT THE CURRENT POSITION

The INCLUDE keyword informs OPM Flow to continue reading input data from the specified INCLUDE file. When the end of the INCLUDE file is reached, or the ENDINC keyword is encountered in the included file, input data is read from the next keyword in the current file.

See *INCLUDE – Load Another Data File at the Current Position* in the GLOBAL section for a full description.

5.3.63 INSPEC – ACTIVATE THE INSPEC FILE OPTION

Description

This keyword switches on the writing of the INIT Index file that specifies and defines the format and data type written to the *.INIT data file. The *.INIT data file contains the static data specified in the GRID, PROPS and REGIONS sections. For example, the PORO, PERM and NTG arrays from the GRID section. The data is used in post-processing software, for example OPM ResInsight, to visualize the static grid properties.

The INIT Index file can either be written out in formatted form as ASCII i.e. text files, if the FMTOUT keyword has been activated (*.FINSPEC), or binary format (*.INSPEC) if the FMTOUT keyword has not been activated. If the INIT keyword in the GRID section has been used to switch on the writing of the *. INIT data file then a binary INIT Index file is automatically written out as well, unless the NOINSPEC keyword in the RUNSPEC section has been used to switch off the writing of the INIT Index file.

Note that most post-processing software require the *.INSPEC file to load the *.INIT data set, although OPM ResInsight does not require this file to be able to load the *.INIT data file.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE WRITING THE INIT INDEX FILE FOR POST-PROCESSING
--
INSPEC
```

The above example switches on the writing of the INIT Index file for post-processing in ResInsight.

5.3.64 LAB - ACTIVATE THE LABORATORY SYSTEM OF UNITS FOR THE MODEL

Description

This keyword switches on the LABORATORY system of units for the model.

OPM Flow has three sets of units, namely: METRIC, FIELD and LAB and one of these keyword should be invoked in the RUNSPEC section to avoid any ambiguity. Both the simulator input and output units are controlled by including one of the METRIC, FIELD or LAB keywords in the RUNSPEC section of the input file.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--        SWITCH ON THE LABORATORY SYSTEM OF UNITS FOR BOTH INPUT AND OUTPUT
--
LAB
```

The above example switches on the LABORATORY system of units for the model.

5.3.65 LGR – DEFINE LOCAL GRID REFINEMENT DIMENSIONS AND PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, LGR, defines maximum dimensions and parameters for the Local Grid Refinement ("LGR") option.

Currently, OPM Flow does not support the local grid refinement feature and therefore this keyword is ignored by the simulator, but is documented here for completeness.

No.	Name	Description	Default
1	MAXLGR	A positive integer value that defines the maximum number of LGRs in the model.	0
2	MAXCLS	A positive integer value that defines the maximum number of grid blocks in all the LGRs.	0
3	MCOARS	A positive integer value that defines the maximum number of amalgamated coarse grid blocks in the model.	0
4	MAMALG	A positive integer value that defines the maximum number of LGR amalgamations in the model.	0
5	MXLALG	A positive integer value that defines the maximum number of LGRs in any amalgamation in the model.	0
6	LSTACK	A positive integer that defines the maximum number of previous search directions stored by the linear solver for the LGR. See the NSTACK keyword in the RUNSPEC section for a full description.	10
7	INTOPT	A character string set to either INTERP to activate the Quandalle[91] pressure correction, or NOINTERP to deactivate this option. The option applies bi-linear interpolation to the global cells surrounding an LGR in order to improve the accuracy of the flow calculations between the LGR and the host cells.	NOINTERP
8	NCHCOR	A positive integer value that defines the maximum number of grid blocks within a coarsened grid that overlap parallel domain boundaries for when the Parallel option has been invoked by the PARALLEL keyword in the RUNSPEC section. OPM Flow uses a different numerical scheme which makes this parameter redundant, see section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to run OPM Flow in parallel mode.	0
Notes: 1) The keyword is terminated by a "/".			

Table 5.19: LGR Keyword Description

[91] *Quandalle, Philippe & Besset, P. (1985). Reduction of Grid Effects Due to Local Sub-Gridding in Simulations Using a Composite Grid. 10.2118/13527-MS.*

Example

```
--
--        LOCAL GRID REFINEMENT DIMENSIONS AND PARAMETERS
--
--        LGR      LGR      LGR      LGR      LGR      LGR     LGR      LGR
--        MAXLGR   MAXCLS   MCOARS   MAMALG   MXLALG   LSTACK  INTOPT   NCHCOR
LGR
          10       1000     1*       1*       1*       1*      INTERP   1*              /
```

The above example sets the maximum number of LGRs to 10 and the maximum number of grid blocks a LGR may contain to 1,000, and that Quandalle pressure correction should be used to improve the flow calculation.

5.3.66 LGRCOPY – ACTIVATE LOCAL GRID REFINEMENT INHERITANCE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LGRCOPY keyword actives Local Grid Refinement ("LGR") Inheritance option that allows the LGR to inherit the properties of the global or host cell containing a LGR grid block at the start of the GRID section, as oppose to the normal process of applying this transform at the end of the GRID section. LGRCOPY can be used in the RUNSPEC, GRID and EDIT sections. If used in the RUNSPEC section then the option is applied to all LGRs defined in the input file, whereas if used in the GRID and EDIT sections the keyword must be placed inside a LGR definition section, that is between a CARFIN (Cartesian LGR grid) or RADIN/RADIN4 (radial LGR grid) and the ENDFIN keyword. In the latter case inheritance is applied on an individual LGR basis.

Currently, OPM Flow does not support the local grid refinement feature and therefore this keyword is ignored by the simulator.

Example

The following example activates the LGR Inheritance option for all LGRs in the model.

```
-- ======================================================================
--
-- RUNSPEC SECTION
--
-- ======================================================================
RUNSPEC
--
--       ACTIVATE LOCAL GRID REFINEMENT INHERITANCE
--
LGRCOPY
```

5.3.67 LICENSES – DEFINE REQUIRED LICENSES FOR RUN

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the additional software licenses that are required to invoke various licensed options in the commercial simulator at the start of the run. The commercial simulator requests a license when keywords associated with a licensed option is encountered in the input deck, this may result in the license being unavailable at the time of request and after the simulation has been initiated, resulting in the run terminating. This keyword avoids this scenario by reserving the license at the start of the run.

OPM Flow is an open source project and therefore there is no license management of the various implemented options; hence this keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.68 LIVEOIL – ACTIVATE THE LIVE OIL PHASE (OIL WITH FREE AND DISSOLVED GAS)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates oil, free and dissolved gas in the model and therefore makes the oil phase live oil[92] in the black-oil formulation, and is equivalent to setting the phases present in the model to be oil, dissolved gas, gas and water phases. Note if water is present in the model this needs to be explicitly stated via the WATER keyword in the RUNSPEC section (see also the BLACKOIL and DEADOIL keywords in the RUNSPEC section). The keyword is used by the commercial simulator's compositional THERMAL option to set the phases present in the model.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

The following example activates the black-oil phases in the model.

```
--
--       ACTIVATE LIVE-OIL PHASE
--
LIVEOIL
```

Alternatively one could explicitly declare the phases using the following keywords in the RUNSPEC section.

```
--
--       OIL PHASE IS PRESENT IN THE RUN
--
OIL
--
--       DISSOLVED GAS IN LIVE OIL IS PRESENT IN THE RUN
--
DISGAS
--
--       GAS PHASE IS PRESENT IN THE RUN
--
GAS
--
--       WATER PHASE IS PRESENT IN THE RUN
--
WATER
```

The above example switches on the oil, dissolved gas, gas and water phases in the model.

[92] *"Live" oil is oil that contains gas in solution, which is normally the case for most conventional oil reservoirs. However, for oil reservoirs classified as heavy oil reservoirs, the in situ dissolved gas may be negligible and oil would then be classified as gas-free oil which is commonly referred to as "dead" oil.*

5.3.69 LOAD – LOAD A SAVE FILE FOR A FAST RESTART

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LOAD keyword loads a previously generated SAVE file to enable a fast restart. A SAVE file contains all the data from a previous run's RUNSPEC, GRID, EDIT, PROPS and REGIONS sections, and thus there is no need for the simulator to calculate various parameters, including grid block transmissibilities etc. This allows for the current run to restart quicker than a conventional restart run using the RESTART keyword in the SOLUTION section via a RESTART file (*.UNRST or *.FUNRST etc.). The keyword should be the first keyword in the input deck and the RUNSPEC, GRID, EDIT, PROPS and REGIONS sections should be deleted from the input deck.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.70 LOWSALT – ACTIVATE THE LOW SALT BRINE PHASE IN THE BRINE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, LOWSALT, activates the low salt brine phase for the Brine option and also activates the Brine option. See also the BRINE keyword in the RUNSPEC section.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE THE LOW SALT BRINE PHASE FOR THE BRINE OPTION
--
LOWSALT
```

The above example declares that the low salt brine phase is active in the model for the Brine option.

5.3.71 MEMORY – DEFINE ALLOCATED MEMORY (RETIRED)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the memory allocation for the run.

OPM Flow and now the commercial simulator uses dynamic memory allocation and therefore the keyword has no effect and is ignored by both simulators.

5.3.72 MESSAGE – OUTPUT USER MESSAGE

The MESSAGE keyword outputs a user message to the terminal, as well as to the print (*.PRT) and debug (*.DBG) files. Note this is different to the MESSAGES keyword, that defines OPM Flows message print limits and stop limits generated by the simulator.

See *MESSAGE – Output User Message* in the GLOBAL section for a full description.

5.3.73 MESSAGES – DEFINE MESSAGE PRINT LIMITS AND STOP LIMITS

The MESSAGES keyword defines the print and stops levels for various messages. The "print limits" set the maximum number of messages that will be printed, after which no more messages will be printed and the "stop limits" terminate the run when these limits are exceeded. There are six levels of message that increase in severity from informative all the way to programming errors, as outlined in Error: Reference source not found.

See *MESSAGES – Define Message Print Limits and Stop Limits* in the GLOBAL section for a full description.

5.3.74 MESSSRVC - ACTIVATE OR DEACTIVATE DATABASE MESSAGE FILE OUTPUT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MESSSRVC keyword activates or deactivates output to the database message file (*.DBPRTX). The file contains all the messages from run in binary format and is used in some post-processing software to annotate production line plots from the run.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.75 METRIC – ACTIVATE THE METRIC SYSTEM OF UNITS FOR THE MODEL

Description

This keyword switches on the METRIC system of units for the model.

OPM Flow has three sets of units, namely: METRIC, FIELD and LAB and one of these keyword should be invoked in the RUNSPEC section to avoid any ambiguity. Both the simulator input and output units are controlled by including one of the METRIC, FIELD or LAB keywords in the RUNSPEC section of the input file.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       SWITCH ON THE METRIC SYSTEM OF UNITS FOR BOTH INPUT AND OUTPUT
--
METRIC
```

The above example switches on the METRIC system of units for the model.

5.3.76 MICP – ACTIVATE THE MICROBIALLY INDUCED CALCITE PRECIPITATION MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MICP keyword activates the Microbially Induced Calcite Precipitation ("MICP") model for the run. MICP is a new and sustainable technology which utilizes biochemical processes to create barriers by calcium carbonate cementation, the technology has the potential to be used for sealing leakage zones in geological formations. Further information on the mathematical model can be found in the open-access publications Landa-Marbán et al[93] and [94].

Note

This is an OPM Flow specific keyword used to investigate CO2 leakage remediation. The module requires that both the MICP and WATER keywords in the RUNSPEC to be active.

There is no data required for this keyword and there is no terminating "\" for this keyword.

Example

```
--
--       ACTIVATE THE MICROBIAL INDUCED CALCITE PRECIPITATION MODEL
--
MICP
--
--       WATER PHASE IS PRESENT IN THE RUN
--
WATER
```

The above example declares that the MICP model is active for the run and activates the water phase for the MICP model.

[94] *Landa-Marbán, D., Kumar, K., Tveit, S., Gasda, S.E., 2021. Numerical studies of CO2 leakage remediation by micp-based plugging technology. In: Røkke, N.A. and Knuutila, H.K. (Eds) Short Papers from the 11th International Trondheim CCS conference, ISBN: 978-82-536-1714-5, 284-290.*

5.3.77 MINNPCOL - DEFINE THE MINIMUM NUMBER OF NEWTON ITERATIONS USED TO UPDATE WELL TARGETS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MINNPCOL keyword defines the minimum number of Newton iterations within a time step that may be used to update the well production and injection targets, after which the well targets will be frozen until the time step calculations have converged and the time step is complete.

Note

This is an OPM Flow specific keyword that sets the minimum number of Newton iterations, as opposed to the commercial simulator's NUPCOL keyword that defines the maximum number of Newton iterations within a time step, after which well targets are frozen.

Wells under group control may suffer from some dependency with other wells in the same group that are under group control. This may cause some oscillation in the production and injection well rates within the group. In order to avoid this, the NUPCOL keyword in the RUNSPEC section can be used to set the maximum number of Newton iterations within a time step, after which the group well rates are frozen until the time step has converged. Reducing the potential of well rate oscillations within the time step may result in the group targets and limits not being exactly met in this case. Increasing the value of NUPCOL, will improve the accuracy of the group targets and limits at the expense of computational efficiency. Here, the MINNPCOL set the minimum number of Newton iterations.

See also section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to set various other numerical control parameters for OPM Flow.

No.	Name	Description	Default
1	MINNPCOL	A positive integer that defines the minimum number of Newton iterations used to update well targets within a time step. Note that default value of six is different to the commercial simulator's default value of three used on the NUPCOL keyword in the RUNSPEC section.	6
Notes: 1) The keyword is terminated by a "/".			

Table 5.20: MINNPCOL Keyword Description

Example

```
--
--       DEFINE THE MIN NUMBER OF ITERATIONS TO UPDATE WELL FLOW TARGETS
--
MINNPCOL
         6                                                                  /
```

The above example sets the default MINNPCOL value to the default value of six.

5.3.78 MISCIBLE – DEFINE MISCIBILITY TODD-LONGSTAFF PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MISCIBLE keyword defines the options associated with the Todd-Longstaff[95] mixing parameters used for when polymer flooding or CO2 EOR simulation cases are being run.

No.	Name	Description	Default
1	NTMISC	A positive integer value that declares the number miscible residual oil saturations versus water saturations tables for SORWMIS keyword and the number Todd-Longstaff mixing parameters entries on the TLMIXPAR keyword.	1
2	NSMISC	A positive integer value that sets the maximum number of entries (or rows) for each SORWMIS table defined by the SORWMIS keyword.	20
3	MISOPT	A character string that defines the numerical dispersion control options for the oil and gas relative permeability curves, set to either NONE or TWOPOINT: 1) NONE – standard single point up streaming, that is using the immediate neighbor 2) TWOPOINT – two-point up streaming, that is using the immediate neighbor plus one cell for better numerical dispersion control but with a higher computational cost. Only the default value of NONE is supported.	NONE
Notes: 1) The keyword is terminated by a "/".			

Table 5.21: MISCIBLE Keyword Description

Example

```
--
--        NTAB     MAX      UPSTRM
--        NTMISC   NSMISC   MISOPT
MISCIBLE
          1        20       NONE                                    /
```

The above example defines the default values for the MISCIBLE keyword, that is one table with a maximum of 20 rows per table using the standard one cell upstream option.

[95] *M. R. Todd and W. J Longstaff, The Development, Testing, and Application Of a Numerical Simulator for Predicting Miscible Flood Performance". In: J. Petrol. Tech. 24.7 (1972), pages 874-882.*

5.3.79 MONITOR – ACTIVATE OUTPUT OF THE MONITORING DATA AND FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MONITOR keyword activates the writing out of the run time monitoring information used by post-processing graphics software to display run time information, for example the simulated production and injection rates and cumulative values. OPM Flow does not have this functionality.

Hence, OPM Flow ignores this keyword but it is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE MONITORING OUTPUT DATA AND FILES
--
MONITOR
```

The above example switches on the output required for run time monitoring required by post-processing graphics software to review the simulation results in real time as the run progresses; however, this has no effect in OPM Flow input decks.

5.3.80 MSGFILE – ACTIVE OR DEACTIVATE MESSAGE FILE OUTPUT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MSGFILE keyword activates or deactivates the message file output used by pre- and post-processing software. Note that message file processing is not available in OPM Flow.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description	Default
1	MSGOPT	A positive integer set to 0 for to deactivate message file output or 1 to activate message file output.	1
Notes: 1) The keyword is terminated by a "/".			

Table 5.22: MSGFILE Keyword Description

Example

```
--
--        OUTPUT
--        OPTN
MSGFILE
          0                                                                    /
```

The above example deactivates the message file output, but the keyword is ignored by OPM Flow.

5.3.81 MULTIN – ACTIVATE THE NON-UNIFIED MULTIPLE INPUT FILE OPTION

Description

This keyword switches on the Multiple Input Files option for all input files. Similar to the commercial simulator, OPM Flow has various options for reading various input files and writing the resulting OPM Flow output files as described in Table 5.23.

Process	Keyword	Description	Files
Input	FMTIN	A character string that defines the input files to be formatted as ASCII i.e. text files, as oppose to binary files. The input deck file is always of this type. The option relates to the OPM Flow derived files that used as input, for for example when restarting from another case. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTIN	A character string that defines the input files to be non-unified multiple files, as opposed to unified files. In this case, one file is read in per reporting time step, as opposed to all time steps reports being read from one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001
	UNIFIN	A character string that defines the input files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. For this option a single summary file and a single restart file will be read. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY
Output	FMTOUT	A character string that sets all output files to be formatted as ASCII i.e. text files, as opposed to binary files. The *.PRT, *.LOG and *.DBG files are always of this type. The option relates to the OPM Flow output files only. In this case the files will be portable across operating systems, but will also be very large in terms of hard disk space. For this reason it is recommend that the default option is used so that binary files are outputted. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTOUT	A character string that defines the output files to be non-unified multiple files, as opposed to unified files. In this case, one file is written for each reporting time step, as opposed to all time steps reports being written in one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001

Process	Keyword	Description	Files
	UNIFOUT	A character string that defines the output files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. Here a single summary file and a single restart file will be generated, as opposed to one file per report time step. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY

Notes:

1) A binary file is computer-readable but not human-readable. All executable programs are stored in binary files, as are most numeric data files. In contrast, text files are stored in a form (usually ASCII) that is human-readable.
2) For unified files if the run terminates unexpectedly, or there is sufficient disk space, then the last report output is not stored. Their main advantage is that if a number of simulations reside in one directory, their output is organized. There is no limit on the number of reporting steps that a unified file can store.

Table 5.23: MULTIN Keyword Description

There is no data required for this keyword.

See also *OPM FLOW OUTPUT FILE FORMATS* for a more detailed description of the various file types (ASCII or binary) and file structure formats (unified or non-unified formats).

Example

```
--
--       ACTIVATE THE MULTIPLE INPUT FILES OPTION
--
MULTIN
```

The above example switches on the multiple input file option.

5.3.82 MULTOUT – ACTIVATE THE NON-UNIFIED MULTIPLE OUTPUT FILE OPTION

Description

This keyword switches on the Multiple Output Files option for all output files. Similar to the commercial simulator, OPM Flow has various options for reading various input files and writing the resulting OPM Flow output files as described in Table 5.24.

Process	Keyword	Description	Files
Input	FMTIN	A character string that defines the input files to be formatted as ASCII i.e. text files, as oppose to binary files. The input deck file is always of this type. The option relates to the OPM Flow derived files that used as input, for for example when restarting from another case. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTIN	A character string that defines the input files to be non-unified multiple files, as opposed to unified files. In this case, one file is read in per reporting time step, as opposed to all time steps reports being read from one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001
	UNIFIN	A character string that defines the input files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. For this option a single summary file and a single restart file will be read. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY
Output	FMTOUT	A character string that sets all output files to be formatted as ASCII i.e. text files, as opposed to binary files. The *.PRT, *.LOG and *.DBG files are always of this type. The option relates to the OPM Flow output files only. In this case the files will be portable across operating systems, but will also be very large in terms of hard disk space. For this reason it is recommend that the default option is used so that binary files are outputted. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTOUT	A character string that defines the output files to be non-unified multiple files, as opposed to unified files. In this case, one file is written for each reporting time step, as opposed to all time steps reports being written in one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001

Process	Keyword	Description	Files
	UNIFOUT	A character string that defines the output files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. Here a single summary file and a single restart file will be generated, as opposed to one file per report time step. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY

Notes:

1) A binary file is computer-readable but not human-readable. All executable programs are stored in binary files, as are most numeric data files. In contrast, text files are stored in a form (usually ASCII) that is human-readable.
2) For unified files if the run terminates unexpectedly, or there is sufficient disk space, then the last report output is not stored. Their main advantage is that if a number of simulations reside in one directory, their output is organized. There is no limit on the number of reporting steps that a unified file can store.

Table 5.24: MULTOUT Keyword Description

There is no data required for this keyword.

See also *OPM FLOW OUTPUT FILE FORMATS* for a more detailed description of the various file types (ASCII or binary) and file structure formats (unified or non-unified formats).

Example

```
--
--       ACTIVATE THE MULTIPLE OUTPUT FILES OPTION
--
MULTOUT
```

The above example switches on the multiple output file option.

5.3.83 MULTOUTS – ACTIVATE NON-UNIFIED MULTIPLE SUMMARY OUTPUT FILE OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword switches on the Multiple Output Files option for SUMMARY files only, and overwrites the UNIFOUT keyword in the RUNSPEC section that activates the Unified Output Files option for all output files.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

See also *OPM FLOW OUTPUT FILE FORMATS* for a more detailed description of the various file types (ASCII or binary) and file structure formats (unified or non-unified formats).

Example

```
--
--       ACTIVATE MULTIPLE OUTPUT SUMMARY FILES ONLY OPTION
--
MULTOUTS
```

The above example switches on the multiple output file option.

5.3.84 MULTREAL – ACTIVATE COMMERCIAL SIMULATOR'S MULTI-REALIZATION LICENSE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MULTREAL keyword activates the commercial simulator's Multi-Realization License option.

OPM Flow is an open source project and therefore there is no license management of the various implemented options; hence this keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.85 NETWORK – ACTIVATE THE EXTENDED NETWORK OPTION AND DEFINE PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates the Extended Network option and defines the maximum number of nodes and links (branches) in the network. The Extended Network option is a different facility to the Standard Network facility, as such, this keyword should only be used if the former network is required for the run.

No.	Name	Description	Default
1	NODMAX	NODMAX is a positive integer that defines the maximum number of nodes in the Extended Network model.	None
2	NBRMAX	NBRMAX is a positive integer that defines the maximum number of links in the Extended Network model.	None
3	NBCMAX	NBCMAX is a positive integer that defines the maximum number of branches that can be connected to a node in the Extended Network model, used in the commercial compositional simulator. The parameter is ignored by OPM Flow and should be defaulted or set to the default value of 20.	20
Notes: 1) The keyword is terminated by a "/".			

Table 5.25: NETWORK Keyword Description

Example

```
--
--        ACTIVATE THE EXTENDED NETWORK OPTION AND DEFINE PARAMETERS
--
--        MAX.     MAX      NOT
--        NODE     LINK     USED
NETWORK
          10        12      1*                                          /
```

In the above example the maximum number of nodes is set equal to ten and the maximum number of links (or branches) is set equal to 12, for the Extended Network option.

5.3.86 NINEPOIN – ACTIVATE THE NINE-POINT DISCRETIZATION OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NINEPOIN keyword activates the Nine-Point Discretization formulation for the whole grid. If the keyword is absent from the run then the conventional standard five-point discretization formulation is used for the model. The nine-point scheme is based on adding additional non-neighbor connections between the diagonal neighbors in the areal plane, in order to reduce grid orientation effects[96].

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

In none Local Grid Refinement runs the NINENUM keyword in the GRID section may be use to optionally set parts of the grid to use nine-point discretization and the remaining regions to use the conventional standard five-point discretization formulation.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE THE NINE-POINT DISCRETIZATION OPTION
--
NINEPOIN
```

The above example switches on the Nine-Point Discretization option for the whole grid.

[96] *Yanosik, J. L. and McCracken, T. A. "A Nine-Point, Finite-Difference Reservoir Simulator for Realistic Prediction of Adverse Mobility Ratio Displacements," paper SPE 5734, Society of Petroleum Engineers Journal (1979) 19, No. 4, 253-262.*

5.3.87 NMATRIX – ACTIVATE THE DISCRETIZED MATRIX DUAL POROSITY OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NMATRIX keyword activates the Discretized Matrix Dual Porosity option and specifies the number of sub-grid blocks in the actual matrix grid blocks. See also the NMATOPS keyword in the GRID section that defines various parameters for this option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	NMATRIX	A positive integer value that specifies the number of sub-grid blocks in the actual matrix grid blocks.	1
Notes: 1) The keyword is terminated by a "/".			

Table 5.26: NMATRIX Keyword Description

Note the keyword cannot be used in conjunction with the TRPLPORO keyword, which is also in the RUNSPEC section.

Example

```
--
--        SUB-GRIDS
--        NMATRIX
NMATRIX
          4                                                    /
```

The above example activates the Discretized Matrix Dual Porosity option and specifies the number of sub-grid blocks in the actual matrix grid block to be four.

5.3.88 NNEWTF – ACTIVATE THE NON-NEWTONIAN FLUID MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates the Non-Newtonian Fluid phase and model for when the polymer phase is present in the model, as indicated by the POLYMER keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	NTHRBL	A positive integer that defines the maximum number of Herschel-Bulkley versus polymer concentration tables to be used with the polymer model, as entered via the FHERCHBL keyword in the PROPS section. The tables are allocated to different parts of the grid by the HBNUM keyword in the REGION section	NTPVT
2	NLNHBL	A positive integer that defines the maximum number of rows for each table entered by the FHERCHBL keyword in the PROPS section.	2

Notes:

1) The exact number of NTHRBL tables are required to completed the data set. For example, if NTHRBL is set equal to three, then there must be three tables entered for the FHERCHBL keyword.
2) The keyword is terminated by a "/".

Table 5.27: NNEWTF Keyword Description

Example

```
--
--        MAX      MAX
--        NTHRBL   NLNHBL
NNEWTF
           3       5                                                    /
```

The above example defines maximum number of Herschel-Bulkley tables to be three with a maximum number of rows for each table set to five.

5.3.89 NOCASC – ACTIVATE LINEAR SOLVER TRACER ALGORITHM

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

NOCASC keyword activates the linear solver tracer algorithm for single phase tracers.

OPM Flow uses a different numerical scheme which makes this keyword redundant; hence, OPM Flow ignores this keyword. It is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--        TRACER SOLVER OPTION
--
NOCASC
```

The above example switches on the linear solver tracer algorithm; however, this has no effect in OPM Flow input decks.

5.3.90 NODPPM – DEACTIVATE FRACTURE POROSITY-PERMEABILITY CALCULATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NODPPM keyword deactivates the default behavior of multiplying the fracture porosity by the fracture permeability to calculate the effective fracture permeability in dual porosity and dual permeability runs. Either the DUALPORO or DUALPERM keywords in the RUNSPEC section must be declared in the input file in order to use this keyword. If the default calculation is switched off by this keyword, then the effective fracture permeability is taken to be those entered for the fracture using the PERMX, PERMY and PERMZ keywords in the GRID section. If the keyword is absent from the input deck, then the entered PERMX, PERMY and PERMZ arrays for the fractures are multiplied by fracture PORO array values in order to obtain the effective fracture permeability.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       DEACTIVATE FRACTURE POROSITY-PERMEABILITY CALCULATION
--
NODPPM
```

The above example switches off the default behavior of multiplying the fracture porosity by the fracture permeability to calculate the effective fracture permeability.

5.3.91 NOECHO – DEACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns off echoing of all the input files to the print file. Note by default echoing of the inputs files is active. but can subsequently be switched off by the NOECHO activation keyword.

See *NOECHO – Deactivate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

5.3.92 NOHYST - DEACTIVATE THE HYSTERESIS OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NOHYST keyword deactivates the Hysteresis option and informs the simulator to ignore the IMBNUM array in the REGIONS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       DEACTIVATE THE HYSTERESIS OPTION
--
NOHYST
```

The above example switches off the default behavior of multiplying the fracture porosity by the fracture permeability to calculate the effective fracture permeability.

5.3.93 NOINSPEC – DEACTIVATE OUTPUT OF THE INIT INDEX FILE

Description

The NOINSPEC keyword deactivates the writing out of the INIT index file (*.INSPEC). The initialization data (or static data) is written out to two files one file contains the data, *.INIT, and the second file contains an index of the data (*.INSPEC) stored in the *.INIT file. This functionality is redundant as most post-processing software require the *.INSPEC file to load the *.INIT data set.

Hence, OPM Flow ignores this keyword. It is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       DEACTIVATE OUTPUT OF THE INIT INDEX FILE *.INSPEC
--
NOINSPEC
```

The above example switches off the writing of the INIT index file (*.INSPEC); however, this has no effect in OPM Flow input decks.

5.3.94 NOMONITO – DEACTIVATE OUTPUT OF THE MONITORING DATA AND FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NOMONITO keyword deactivates the writing out of the run time monitoring information used by post-processing graphics software to display run time information, for example the simulated production and injection rates and cumulative values. OPM Flow does not have this functionality.

Hence, OPM Flow ignores this keyword but it is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       DEACTIVATE MONITORING OUTPUT DATA AND FILES
--
NOMONITO
```

The above example switches off the output required for run time monitoring required by post-processing graphics software to review the simulation results in real time as the run progresses; however, this has no effect in OPM Flow input decks.

5.3.95 NONNC – DEACTIVATE NON-NEIGHBOR CONNECTIONS

Description

The NONNC keyword deactivates non-neighbor connections ("NNCs") in the current run. NNCs create off-diagonal elements in the Jacobi matrix that impact the numerical efficiency of the solution algorithms, and thus if the run does not contain NNC's then there is the potential for greater computation efficiency. Unfortunately, nearly all models, except for the most simple models, generate NNCs via for example:

1) aquifer connections,
2) faults, and
3) manually entered NNCs, including those automatically generate by pre-processing software.

Due to the limited application of this option, the feature has not been implemented in OPM Flow and hence OPM Flow ignores this keyword. It is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       DEACTIVATE NON-NEIGHBOR CONNECTIONS
--
NONNC
```

The above example switches off the NNCs; however, this has no effect in OPM Flow input decks.

5.3.96 NORSSPEC – DEACTIVATE OUTPUT OF THE RESTART INDEX FILE

Description

The NORSSPEC keyword deactivates the writing out of the RESTART index file (*.RSSPEC). The restart data (pressure, saturations etc. through time for each active cell) are written out to two files one file contains the data, *.UNRST for example, and the second file contains an index of the data (*.RSSPEC) stored in the *.UNRST file. This functionality is redundant as most post-processing software require the *.RSSPEC file to load the *.UNRST data set.

Hence, OPM Flow ignores this keyword. It is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       DEACTIVATE OUTPUT OF THE RESTART INDEX FILE *.RSSPEC
--
NORSSPEC
```

The above example switches off the writing of the restart index file (*.RSSPEC); however, this has no effect in OPM Flow input decks.

5.3.97 NOSIM – ACTIVATE THE NO SIMULATION MODE FOR DATA FILE CHECKING

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

NOSIM switches the mode of OPM Flow to data input checking mode. In this mode the input file is read and all messages and print instructions are sent to the respective output files. The SCHEDULE section is read but the simulation is not performed.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

The example below switches OPM Flow to no simulation mode for data checking of the input deck.

```
--
--       SWITCH NO SIMULATION MODE FOR DATA CHECKING COMMENT OUT TO RUN THE MODEL
--
NOSIM
```

And the next example shows how to commented out the NOSIM activation keyword so that the simulation will proceed.

```
--
--       SWITCH NO SIMULATION MODE FOR DATA CHECKING COMMENT OUT TO RUN THE MODEL
--
-- NOSIM
```

Note

Simulation input decks are complex and are therefore prone to typing errors, thus before submitting a run that will take over 15 minutes or so, it is a good idea to run the model with the NOSIM option. If no errors are found then the NOSIM keyword should be commented out by placing "--" before the keyword, and then re-running the model.

Alternatively, one could use OPMRUN to run all the jobs in the queue in NOSIM mode and have the software re-run jobs in simulation mode if there are no errors.

5.3.98 NOWARN – DEACTIVATE WARNING MESSAGES

Turns off warning messages to be printed to the print file; note that this keyword is deactivated by default and can subsequently be switched off by the WARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN.

See *NOWARN – Deactivate Warning Messages* in the GLOBAL section for a full description.

5.3.99 NRSOUT – DEFINED MAXIMUM NUMBER OF RESTART ELEMENTS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NRSOUT keyword specifies the maximum number of elements that can be written to the RESTART file at each reporting time step.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	NRSOUT	A positive integer value that specifies the maximum number of elements that can be written to the RESTART file at each reporting time step.	3600

Notes:

1) The keyword is terminated by a "/".

Table 5.28: NRSOUT Keyword Description

Example

```
--
--        MAX
--        NRSOUT
NRSOUT
          6000                                                    /
```

The above example sets the maximum number of elements that can be written to the RESTART file at each reporting time step to 6000.

5.3.100 NSTACK – DEFINE THE STACK LENGTH FOR THE ITERATIVE LINEAR SOLVER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NSTACK keyword defines the maximum number of previous search directions stored by the linear solver. Increasing the value of NSTACK may improve the efficiency of the solver on difficult problems, but will increase the memory requirements of the simulator. The default value of 10 should be sufficient for most problems; however, if OPM Flow is having issues with the convergence of the linear questions then increasing NSTACK and LITMAX on the TUNING keyword may improve performance.

OPM Flow uses a different numerical scheme which makes this keyword redundant; see section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description	Default
1	NSTACK	A positive integer that defines the maximum number of previous search directions stored by the linear solver.	10

Notes:

1) NSTACK and LITMAX on the TUNING keyword are related such that NSTACK should always be less than or equal to LITMAX.

2) The keyword is terminated by a "/".

Table 5.29: NSTACK Keyword Description

Example

```
--
--          SET STACK SIZE FOR LINEAR SOLVER
--
NSTACK
            30                                                              /
```

The above example sets maximum number of previous search directions stored by the linear solver to 30, this has no effect in OPM Flow input decks.

Note

If the run is suffering from linear convergence problems, then check the data first for any data issues before manipulating the numerical control parameters. For example, if OPM Flow has written some WARNING messages with respect to end-point scaling, etc., then resolve these messages first before adjusting the numerical controls.

5.3.101 NUMRES – DEFINE THE NUMBER OF RESERVOIR GRIDS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NUMRES keyword defines the number of reservoir grids (COORD data sets) that the simulator should process. Currently, this should only be set to one in OPM Flow

No.	Name	Description	Default
1	NUMRES	A positive integer greater than one that defines the maximum number COORD data sets to be processed by OPM Flow. This should be set to one.	1
Notes: 1) The keyword is terminated by a "/".			

Table 5.30: NUMRES Keyword Description

Example

```
--
--       DEFINE THE NUMBER OF RESERVOIR GRIDS (COORD DATA SETS)
--
NUMRES
         1                                                                  /
```

The above example sets the maximum number of COORD data sets to be processed to one, this is the only value that can currently be used in OPM Flow.

5.3.102 NUPCOL – DEFINE THE MAXIMUM NUMBER OF NEWTON ITERATIONS USED TO UPDATE WELL TARGETS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NUPCOL keyword defines the maximum number of Newton iterations within a time step that may be used to update the well production and injection targets, after which the well targets will be frozen until the time step calculations have converged and the time step is complete.

Wells under group control may suffer from some dependency with other wells in the same group that are under group control. This may cause some oscillation in the production and injection well rates within the group. In order to avoid this, after the number Newton iterations within a time step surpasses NUPCOL, the group well rates are frozen until the time step has converged. Reducing the potential of well rate oscillations within the time step may result in the group targets and limits not being exactly met in this case. Increasing the value of NUPCOL to greater than the default value of six, will improve the accuracy of the group targets and limits at the expense of computational efficiency.

See also section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to set various other numerical control parameters for OPM Flow.

No.	Name	Description	Default
1	NUPCOL	A positive integer that defines the maximum number of Newton iterations used to update well targets within a time step. Note that default value of six is different to the commercial simulator's default value of three.	6
Notes: 1) The keyword is terminated by a "/".			

Table 5.31: NUPCOL Keyword Description

See also the MINNPCOL keyword in the RUNSPEC section that sets the minimum number of Newton iterations within a time step that may be used to update the well production and injection targets, after which the well targets will be frozen until the time step calculations have converged and the time step is complete. Note that MINNPCOL is an OPM Flow specific keyword.

Example

```
--
--       DEFINE THE MAX NUMBER OF ITERATIONS TO UPDATE WELL FLOW TARGETS
--
NUPCOL
        6                                                                  /
```

The above example sets the default NUPCOL value to the default value of six.

5.3.103 OIL – ACTIVATE THE OIL PHASE IN THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword indicates that the oil phase is present in the model and must be used for oil-gas, oil-water, oil-water-gas input decks that contain the oil phase. The keyword will also invoke data input file checking to ensure that all the required oil phase input parameters are defined in the input deck.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       OIL PHASE IS PRESENT IN THE RUN
--
OIL
```

The above example declares that the oil phase is active in the model.

5.3.104 OPTIONS – ACTIVATE VARIOUS PROGRAM OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The OPTIONS keyword activates various program options in the commercial simulator. Currently, none of the options available in the commercial simulator are implemented in OPM Flow, and it is unlikely that this keyword will be supported in the future releases of OPM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Description	Default
1 - 273	Commercial simulator options keyword, used to to switch on or off specific features. The keyword is commonly used to revert the simulator's behavior to past functionality that has been depreciated in the current version of the commercial simulator, for backward compatibility with previous models.	0

Notes:

1) The keyword is terminated by a "/".

Table 5.32: OPTIONS Keyword Description

Examples

```
--
--        SKIP       ACTIVATE
--        OPTIONS    OPTION
OPTIONS
          77*0       1                                                  /
```

The above example activates the use of scratch files for pre-processing grid geometry data for non-neighbor connections. Note if multiple options are required then one can just repeat the format of the example to activate multiple options as the keyword does not overwrite previous entries. So for example:

```
--
--        SKIP       ACTIVATE
--        OPTIONS    OPTION
OPTIONS
           7*0       1                                                  /
--
--        SKIP       ACTIVATE
--        OPTIONS    OPTION
OPTIONS
          77*0       1                                                  /
--
--        SKIP       ACTIVATE
--        OPTIONS    OPTION
OPTIONS
          177*0      1                                                  /
```

Could be used to activate the 8, 78 and 178 options if they were available.

5.3.105 PARALLEL – DEFINE PARALLEL RUN CONFIGURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PARALLEL keyword defines the run to use parallel processing and sets the domain decomposition options. See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to run OPM Flow in parallel mode.

No.	Name	Description	Default
1	NPROCS	A positive integer that defines the number of domains or parallel processors to use for this run.	1
2	RTYPE	A character string set to either SERIAL to run the parallel code in serial mode for testing the code, or DISTRIBUTED to full utilize parallel processing.	PARALLEL
Notes: 1) The keyword is terminated by a "/".			

Table 5.33: PARALLEL Keyword Description

OPM Flow uses a different numerical scheme which makes this keyword redundant; hence, OPM Flow ignores this keyword. It is documented here for completeness.

Example

```
--
--       PARALLEL MULTI-CORE OPTIONS
--       NDMAIN     MACHINE TYPE
PARALLEL
           2        DISTRIBUTED                                              /
```

The above example sets the number of domains (or processors) to two and for the simulation to run in parallel mode. This has no effect in OPM Flow input decks.

5.3.106 PARTTRAC – ACTIVATE AND DEFINE PARTITIONED TRACER OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PARTTRAC keyword activates the Partitioned Tracer option and defines the maximum number of partitioned tracers, the number of TRACERKP or TRACERKM partitioning tables in the PROPS section, and the maximum number of number of rows in the TRACERKP or TRACERKM partitioning tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.107 PATHS – DEFINE FILENAME DIRECTORY PATH ALIASES

Description

PATHS allows the user to define alias directory filenames to avoid long filenames with the INCLUDE, IMPORT, RESTART or GDFILE keywords. To use the alias with the aforementioned keywords PATHS should be prefixed with the $ symbol.

No.	Name	Description	Default
1	ALIAS	A character string enclosed in quotes defining the alias.	None
2	DIRC	A character string enclosed in quotes defining the directory filename.	None

Notes:

1) Multiple entries must be on separate lines (see the example).
2) The keyword is terminated by a "/".

Table 5.34: PATHS Keyword Description

Examples

```
--
--       PATH       PATH
--       ALIAS      DIRECTORY FILENAME
PATHS
        'GRID'      '/DISK1/NORNE/2017/GRID-INCLUDES'                    /
        'SCHD'      '/DISK1/NORNE/2017/SCHD-INCLUDES'                    /
/
```

The above example defines "GRID" and "SCHD" aliases in the RUNSPEC section than can be used in the GRID and SCHEDULE sections of the input deck. The next example shows how to use the "GRID" alias with the INCLUDE keyword in the GRID section.

```
--
--       LOAD INCLUDE FILES
--
INCLUDE
         '$GRID/PORO.INC'                                                /

INCLUDE
         '$GRID/PERMX.INC'                                               /

INCLUDE
         '$GRID/NTG.INC'                                                 /
```

Here the porosity, permeability and net-to-gross arrays are loaded in the GRID section using the directory filename aliases declared in the RUNSPEC section.

5.3.108 PEDIMS – DEFINE PETRO-ELASTIC MODEL REGIONS AND TABLE DIMENSIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PEDIMS keyword defines the number of petro-elastic regions to be used with the PENUM keyword in the REGIONS section and the number of rows in the PEGTAB0 to PEGTAB7 keywords, as well as the number of rows in the PEKTAB0 to PEKTAB7 keywords in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.109 PETOPTS – DEFINE PETREL AND GENERIC SIMULATION FILE OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PETOPTS keyword defines various Petrel and Generic Simulation (*.GSG) file options.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.110 PIMTDIMS – DEFINE WELL PRODUCTIVITY SCALING TABLE DIMENSIONS

Description

PIMTDIMS keyword defines the maximum number of PIMULTAB tables and the maximum number of entries (or rows) per PIMULTAB table. The PIMULTAB keyword is used to define a well's productivity index factor as a function of a well's producing water cut.

No.	Name	Description	Default
1	NTPIMT	A positive integer value that defines the maximum number of PIMULTAB keywords defined in the input deck.	0
2	NRPIMT	A positive integer value defining the maximum number of entries (rows) in the PIMULTAB keyword.	0
Notes: 1) The keyword is terminated by a "/".			

Table 5.35: PIMTDIMS Keyword Description

Example

```
--
--        MAX     MAX
--        TABLES  ENTRIES
PIMTDIMS
          1       51                                                    /
```

The above example defines that there is one PIMULTAB table with a maximum number of 51 rows.

5.3.111 PINTDIMS – DEFINE POLYMER MOLECULAR WEIGHT MODEL TABLE DIMENSIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PINTDIMS keyword defines the number of property tables used in the OPM Flow's Polymer Molecular Weight Transport option, that uses the polymer molecular weight in calculating the polymer viscosity, as well as accounting for formation damage due to the water and polymer injection, by adjusting the wellbore skin pressure. This keyword should only be used if the POLYMER and POLYMW keywords in the RUNSPEC section are also activated. The PINTDIMS keyword defines the maximum number of tables for the SKPRWAT, SKPRPOLY, and PLYMWINJ keywords, and the number of entries in the PLYVMH keyword. All the aforementioned keywords are in the PROPS section.

Note

This is an OPM Flow specific keyword that employs an alternative polymer flood model based on a Polymer Molecular Weight Transport equation, that is not available in the commercial simulator.

No.	Name	Description	Default
1	NTSKWAT	NTSKWAT is a positive integer that defines the number of SKPRWAT tables in the PROPS section, used to describe the relationship of wellbore skin pressure as a function of water throughput and water velocity, for the simulator's Polymer Molecular Weight Transport option.	1
2	NTSKPOLY	NTSKPOLY is a positive integer that defines the number of SKPRPOLY tables in the PROPS section, used to describe the relationship of wellbore skin pressure as a function of polymer throughput and polymer velocity, for the simulator's Polymer Molecular Weight Transport option.	1
3	NTPMWINJ	NTPMWINJ is a positive integer that defines the number of PLYMWINJ tables in the PROPS section, used to describe the relationship of the injected polymer molecular weight as a function of polymer throughput and polymer velocity, for the simulator's Polymer Molecular Weight Transport option.	1
4	NPLYVMH	NPLYVMH is a positive integer that defines the maximum number of entries (rows) in the PLYVMH table in the PROPS section, used to describe the relationship of the injected polymer viscosity as a function of polymer molecular weight and polymer concentration, for the simulator's Polymer Molecular Weight Transport option.	1
Notes: 1) The keyword is terminated by a "/".			

Table 5.36: PINTDIMS Keyword Description

The SKPRWAT, SKPRPOLY, PLYMWINJ, and PLYVMH keywords in the PROPS section, are the additional keywords required for the Polymer Molecular Weight Transport option. Note that the standard polymer property data keywords: PLYROCK, PLYADS, PLYMAX, etc., are still required to fully describe the polymer fluid.

Example

```
--
--       POLYMER MOLECULAR WEIGHT TRANSPORT TABLES (OPM FLOW RUNSPEC KEYWORD)
--
--       NO.       NO.       NO.       NO.
--       NTSKWAT   NTSKPOLY  NTPMWINJ  NPLYVMH
PINTDIMS
         2         2         2         1                                     /
```

The above example declares two SKPRWAT, SKPRPOLY, and PLYMWINJ keywords in the PROPS section will be used, as well as the default value of one for the number of rows in the PLYVMH keyword.

5.3.112 POLYMER – ACTIVATE THE POLYMER PHASE IN THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword indicates that the polymer phase is present in the model and to activate the polymer flooding model. The keyword will also invoke data input file checking to ensure that all the required polymer phase input parameters are defined in the input deck.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE THE POLYMER PHASE IN THE MODEL
--
POLYMER
```

The above example declares that the polymer phase is active in the model.

5.3.113 POLYMW – ACTIVATE THE POLYMER MOLECULAR WEIGHT TRANSPORT OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates OPM Flow's Polymer Molecular Weight Transport option that uses the polymer molecular weight in calculating the polymer viscosity, as well as accounting for formation damage due to the water and polymer injection, by adjusting the wellbore skin pressure. This keyword should only be used if the POLYMER keyword in the RUNSPEC section is also activated. The keyword will also invoke data input file checking to ensure that all the required polymer phase input parameters are defined in the input deck.

In the PROPS section the PLYVMH, PLYMWINJ, SKPRWAT and SKPRPOLY keywords are used to define the additional polymer and water properties for the model. And the SPOLYMW keyword in the SOLUTION section may be used to set the initial molecular weight for each grid block in the model, in order to initialize the model. In the SCHEDULE section, the WPIMITAB keyword should be used to associate a water injection well with the appropriate PLYMWINJ table. Finally, the WSKPTAB keyword, also in the SCHEDULE section, may be used to define the SKPRPOLY and SKPRWAT tables associated with the skin pressure for polymer and water injection. All the aforementioned keywords are OPM Flow specific keywords, that are not available in the commercial simulator.

Note

This is an OPM Flow specific keyword that employs an alternative polymer flood model based on a Polymer Molecular Weight Transport equation, that is not available in the commercial simulator.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE THE POLYMER PHASE IN THE MODEL
--
POLYMER
--
--       ACTIVATE THE POLYMER MOLECULAR WEIGHT TRANSPORT OPTION
--
POLYMW
```

The above example declares that the polymer phase is present, and that the simulator's Polymer Molecular Weight Transport option should be used instead of the standard polymer model.

5.3.114 PRECSALT – ACTIVATE THE OPM FLOW SALT PRECIPITATION MODEL

Description

This keyword activates the OPM Flow Salt Precipitation model that accounts for salt precipitating out of the water phase when the water is being vaporized into the gas phase and the dissolved salt reaches the solubility limit as the pressure in the reservoir is being depleted (see the VAPWAT keyword in the RUNSPEC section). This facility is an extension to the standard Brine model, and as such the BRINE keyword in the RUNSPEC must also be present in the input deck. In general, if the PRECSALT keyword has been activated in the input deck then the VAPWAT keyword should also be activated. The keyword should only be used if both water and gas phases are active in the model.

Note

This is an OPM Flow specific keyword for the simulator's Salt Precipitation model, note that this is an extension to the commercial simulator's Brine model.

If the keyword is present in the input deck then the SALTSOL keyword in the PROPS section also needs to be present in the input deck to define the salt solubility. In addition, either the SALTPVD or SALTP keywords in the SOLUTION section should be used to define the initial salt precipitated saturation.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

The first part of the example shows the keywords for the RUNSPEC section.

```
-- ==================================================================================
--
-- RUNSPEC SECTION
--
-- ==================================================================================
RUNSPEC
-- ----------------------------------------------------------------------------------
-- FLUID TYPES AND TRACER OPTIONS
-- ----------------------------------------------------------------------------------
--
--       OIL PHASE IS PRESENT IN THE RUN
--
OIL
--
--       WATER PHASE IS PRESENT IN THE RUN
--
WATER
--
--       GAS PHASE IS PRESENT IN THE RUN
--
GAS
--
--       DISSOLVED GAS IN LIVE OIL IS PRESENT IN THE RUN
--
DISGAS
```

```
--
--       ACTIVATE STANDARD BRINE MODEL IN THE RUN
--
BRINE
--
--       ACTIVATE THE OPM FLOW SALT PRECIPITATION MODEL (OPM FLOW KEYWORD)
--
PRECSALT
```

The above example declares that the oil, water, gas, dissolved gas, and brine phases are present in the model, and activates the Brine (BRINE keyword) and Salt Precipitation (PRECSALT keyword) models.

The second part of the example shows the additional PVT fluid keywords require for the Salt Precipitation model in the PROPS section. Note that in addition to the Salt Precipitation model specific keywords, the standard DENSITY (or GRAVITY), PVDG, and PVTO keywords are required.

```
-- ======================================================================
--
-- PROPS SECTION
--
-- ======================================================================
PROPS
--
--       WATER SALT PVT TABLE
--
PVTWSALT
--       REF PRES  REF SALT
--       PSIA      LB/STB
--       --------  --------
         3000.0    0.000                                  / REFERENCE DATA
--
--       SALTCONC  BW         CW        VISC     VISC
--       LB/STB    RB/STB     1/PSIA    CPOISE   GRAD
--       --------  --------   -------   ------   ------
            0.0    1.0        3.0E-6    1.0      1.0E-6
           10.0    0.8        3.0E-6    1.0      1.0E-6    / SALT CONCENTRATION
--
--       SET SALT SOLUBILITY LIMIT FOR ALL CELLS (OPM FLOW KEYWORD)
--
SALTSOL
--       MAX       SALT
--       SALTSOL   DENSITY
         0.500     135.46867445023383                     /
```

In addition, to the above the PERMFACT keyword may be used to account for the reduction in porosity and permeability due to salt precipitating into the pore space. Again, in addition to the Salt Precipitation model specific keywords, the standard ROCK, SGOF, and SWOF keywords are required.

```
--
--       PERMEABILITY FACTOR REDUCTION DUE TO SALT (OPM FLOW KEYWORD)
--
PERMFACT
--       PORO       PERM
--       FACTOR     FACTOR
--       -------    --------
         0.0         0.000
         0.4         0.005
         0.6         0.010
         0.9         0.100
         1.0         1.000                                  / TABLE NO. 01
/
```

In order to initialize the model in the SOLUTION section, apart from the standard equilibration keywords, the following Salt Precipitation model specific keywords should be included.

```
-- ======================================================================
--
-- SOLUTION SECTION
--
-- ======================================================================
SOLUTION
--
--       PRECIPITATED SALT VOLUME FRACTION VERSUS DEPTH (OPM FLOW KEYWORD)
--
--       DEPTH    SALTPSAT
--       ------   --------
SALTPVD
         8300.0    0.010
         8450.0    0.010                          / SALT VS DEPTH EQUIL REGN 01
--
--       DEPTH    SALT-1    SALT-2    SALT-3
--                SALTCON   SALTCON   SALTCON
--       ------   -------   -------   -------
SALTVD
         8300.0    0.500
         8450.0    0.500                           / SALT VS DEPTH EQUIL REGN 01
```

Note that OPM Flow does not support Multi-Component Brine model, thus there should only one column of salt concentrations.

Finally, in the SCHEDULE section, one may optionally one can add the injections well's injection salt concentrations, as shown below.

```
-- ======================================================================
--
-- SCHEDULE SECTION
--
-- ======================================================================
SCHEDULE
--
--       DEFINE WATER INJECTION WELL SALT CONCENTRATIONS
--
-- WELL  SALT-1     SALT-2     SALT-3     SALT-4
-- NAME  SALTCON    SALTCON    SALTCON    SALTCON
--       -------    -------    -------    --------
WSALT
'INJ'    0.0000                                        /
/
```

Normally, with this option one would also include vaporized water via the VAPWAT keyword in the RUNSPEC section, as well as the PVTGW keyword to define gas PVT properties for dry gas, or the PVTGWO keyword that declares the gas PVT properties for wet gas. Both keywords are in the PROPS

section. The RWGSALT keyword in the PROPS section, may be used to define the relationship of water vaporization versus pressure and salt concentration. Again, the keyword is in the PROPS section. Secondly, in the SOLUTION section, the RVW keyword can be used to set the initial equilibration vaporized water in gas ratio values for all grid cells in the model for Enumeration Initialization, or the RVWVD keyword that declares the vaporized water-gas ratio (Rvw) versus depth tables for each equilibration region, for Equilibrium Initialization.

5.3.115 PSTEADY – ACTIVATE PSEUDO STEADY STATE FLOW CALCULATION OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PSTEADY keyword activates Pseudo Steady State Flow Calculation option by advancing the simulator until it reaches a pseudo steady state flow and then sets the date to the date defined on this keyword, that is written to the RESTART file. Keyword also includes parameters defining the conditions for pseudo steady flow state.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.116 RADIAL – RADIAL GRID ACTIVATION OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

RADIAL activates the radial grid geometry option for the model, if this keyword and the SPIDER keyword are omitted then Cartesian geometry is assumed by OPM Flow.

See also the SPIDER keyword in the RUNSPEC section (*SPIDER – Spider Grid Activation Option*). This is an OPM Flow specific keyword for the simulator's Spider Grid option, that emulates a Radial Grid via corner-point geometry. Both Spider and Radial grids will be displayed the same in OPM ResInsight, as they both use Irregular Corner-Point Grid geometry. The difference is that the radial model's pore volumes are adjusted to match the radial geometry pore volumes, whereas, the Spider grid volumes are not adjusted. See the examples in the section on Radial Grids (*Radial Grids*) and Spider Grids (*Spider Grids*) for further information.

Example

```
--
--       DEFINE RADIAL GRID GEOMETRY
--
RADIAL
```

The example activates the radial grid geometry option.

5.3.117 REGDIMS – DEFINE THE MAXIMUM NUMBER OF REGIONS FOR A REGION ARRAY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The REGDIMS keyword defines the maximum number of regions for various region arrays used in the model. Note that the maximum number of FIPNUM regions can be defined both on this keyword and the TABDIMS keyword, if it set in both locations the maximum value is used. The reason for this type of inconsistency is due to the commercial simulator evolving with time as new features were added, but at the same time having to maintain backward input deck compatibility.

No.	Name	Description	Default
1	NTFIP	A positive integer defining the maximum number of regions in the FIPNUM region array. If additional sets of fluid in-place regions have been defined, as per the FIPxxxxx series of fluid in-place region keywords, then NTFIP should be set to the maximum number of regions in either the FIPNUM or FIPxxxxx associated arrays. Thus, if the maximum number of regions in the FIPNUM array is 12, and the maximum value in the FIPxxxxx series of arrays is 20, then 20 should be entered for NTFIP. Note that this parameter may also be set on the TABDIMS keyword as well. If NTFIP is set in both places, then the maximum value is used.	1
2	NMFIPR	A positive integer defining the total maximum number of fluid in-place regions. The number of FIPNUM regions are defined by NTFIP. However, if additional sets of fluid in-place regions are required, as per the FIPxxxxx series of fluid in-place region keywords, then these are to be defined here by adding the number of FIPxxxxx arrays to the value NTFIP. So for example, if NTFIP equals five and the number of distinct FIPxxxxx regions is three, then the value to enter for NMFIPR is eight.	1
3	NRFREG	A positive integer defining the maximum number of independent reservoir regions in the ISOLNUM region array.	0
4	MXNFLX	A positive integer defining the maximum number of flux regions in the FLUXNUM region array. MXNFLN can also be defined on the TABDIMS keywords as well. If MXNFLX is defined both here and on the TABDIMS keyword then the maximum value of the two is used.	0
5	NUSREG	A positive integer defining the maximum user defined regions in a commercial simulator's compositional model. This parameter is included for compatibility and should be defaulted as it is not used in OPM Flow.	0
6	NTCREG	A positive integer defining the maximum number of regions in the COALNUM region array. This parameter is included for compatibility and should be defaulted as it is not used in OPM Flow.	1
7	NOPREG	A positive integer defining the maximum number of regions in the OPERNUM region array.	0

No.	Name	Description	Default
8	NWKDREG	A positive integer defining the maximum number of real double-precision work arrays for use with the OPERATE and OPERATER keywords. This parameter is included for compatibility and should be defaulted as it is not used in OPM Flow.	0
9	NWKIREG	A positive integer defining the maximum number of integer work arrays for use with the OPERATE and OPERATER keywords. This parameter is included for compatibility and should be defaulted as it is not used in OPM Flow.	0
10	NPLMIX	A positive integer defining the maximum number of regions in the PLMIXNUM region array.	1
Notes: 1) The keyword is terminated by a "/".			

Table 5.37: REGDIMS Keyword Description

Example

```
--
--        MAX     TOTAL   INDEP   FLUX    TRACK   CBM     OPERN   WORK    WORK    POLY
--        FIPNUM  REGNS   REGNS   REGNS   REGNS   REGNS   REGNS   REAL    INTG    REGNS
REGDIMS
          9       12      1*      1*      1*      1*      1*      1*      1*      1*    /
```

The above example defines the number of FIPNUM regions to be nine and the number of FIPxxx type of regions to be three (12 – 9), the rest of the region sizes are set to the default values.

5.3.118 RIVRDIMS – DEFINE THE RIVER DIMENSIONS AND ASSOCIATED DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

RIVRDIMS defines the river system array dimensions used with the REACHES keyword and other river keywords in the SOLUTION and SCHEDULE sections. The keyword also enables the River option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.119 ROCKCOMP – ACTIVATE ROCK COMPACTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ROCKCOMP keyword activates rock compaction and defines various rock compaction options for the run. By default OPM Flow models rock compaction via pore volume compressibility as entered on the ROCK keyword in the PROPS section. This keyword enables pressure dependent pore volume and transmissibility multipliers for rock compaction that are entered in the PROPS section using the ROCKTAB keyword. Currently OPM Flow only supports the default options for rock compaction.

No.	Name	Description	Default
1	ROCKOPT	A character string that defines the rock compaction option based on one of the following character strings: 1) REVERS: Rock compaction is reversible with increasing pressure. The rock compaction multipliers should be entered via the ROCKTAB keyword in the PROPS section. This is the default value. 2) IRREVERS: Rock compaction is irreversible, that is the rock expansion does not occur when the pressure subsequently increases. 3) HYSTER: Invokes the hysteresis rock compaction option. 4) BOBERG: Rock compaction hysteresis is modeled using the Boberg formulation[97]. 5) REVLIMIT: Activates the reversible hysteresis rock compaction option that limits the pore volume subject to reversibility based on the minimum pressure in a grid block and the initial water saturation. This option is only intended to be used with the water induced compaction model, neither of which are currently supported by OPM Flow.. 6) PALM-MAN: Rock compaction hysteresis is modeled using the Palmer-Mansoori[98] and [99] formulation for coal bed methane reservoirs, neither of which are supported by OPM Flow. 7) NONE: Deactivates rock compaction, unless the water induced compaction model has been invoked. Only the REVERS and IRREVERS options are supported by OPM Flow.	REVERS
2	NTROCC	A positive integer that defines the number of rock compaction tables, that is the number of ROCKTAB tables to be used by OPM Flow.	1
3	WATINOPT	A character string that states if the water induced rock compaction option should be used (YES) or not (NO). If set to YES then either the ROCKTABW or the ROCK2D and ROCKWNOD keywords should be entered in the PROPS section.	NO

[97] *Beattie, C.I., Boberg, T.C., and McNab, G.S. "Reservoir Simulation of Cyclic Steam Stimulation in the Cold Lake Oil Sands," paper SPE 18752, Society of Petroleum Engineers Journal, (1991) 6, No. 2, 200-206.*

[98] *Palmer, I. and Mansoori, J. "How Permeability Depends on Stress and Pore Pressure in Coalbeds: A New Model," paper SPE 52607, SPE Reservoir Evaluation & Engineering (1998) 1, No. 6, 539-544.*

[99] *Clarkson, C.R., Pan, Z., Palmer, I. and Harpalani, S. "Predicting Sorption-Induced Strain and Permeability Increase With Depletion for Coalbed-Methane Reservoirs", SPE 114778-PA, SPE Journal (2010) 15, No. 1, 152–159.*

No.	Name	Description	Default
4	PORTXROP	A character string that specifies the model to be used for when transmissibility is dependent on porosity, and should be set to either: 1) EXP: An exponential porosity-transmissibility relationship should be used. 2) CZ: The Carmen-Kozeny[100, 101] and [102] porosity-transmissibility relationship should be used. This option is used in the commercial compositional simulator and is therefore ignored by OPM Flow.	1*
5	CARKZEXP	The exponent constant in the Carmen-Kozeny porosity-transmissibility equation for when PORTXROP has been set to CZ. This option is used in the commercial compositional simulator and is therefore ignored by OPM Flow.	0.0
Notes: 1) The keyword is terminated by a "/".			

Table 5.38: ROCKCOMP Keyword Description

Example

```
--
--        ROCK    NUMBER   WAT      POR-TRAN
--        OPTN    TABLES   INDUCE   OPTION
ROCKCOMP
          REVERS  5        NO       1*                                    /
```

The above example defines the default values for the ROCKCOMP keyword with five rock compaction tables.

5.3.120 RPTCPL – ACTIVATE COUPLE SIMULATION REPORTING

FRUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates the couple simulation reporting, that results in the simulator writing out various initialization data and simulation data in order for external "controlling programs" to interactively manage the simulation. There is no data required for this keyword but the keyword should be terminated by a "/".

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--       ACTIVATE COUPLE SIMULATION REPORTING
--
RPTCPL
/
```

The above example switches on couple simulation reporting; however, this has no effect in OPM Flow input decks.

5.3.121 RPTHMD - DEFINE WELL HISTORY MATCH GRADIENT REPORTING OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, RPTHMD, defines the options and level of history match output that should be written to history match file (*.HMD), for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

5.3.122 RPTRUNSP – ACTIVATE RUNSPEC REPORTING

Description

This keyword activates reporting of all the RUNSPEC options utilized in the run. There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--       ACTIVATE RUNSPEC SECTION REPORTING
--
RPTRUNSP
```

The above example switches on RUNSPEC reporting; however, this has no effect in OPM Flow input decks.

5.3.123 RSSPEC – ACTIVATE OUTPUT OF THE RESTART INDEX FILE

Description

The RSSPEC keyword activates the writing out of the RESTART index file (*.RSSPEC). The restart data (pressure, saturations etc. through time for each active cell) are written out to two files one file contains the data, *.UNRST for example, and the second file contains an index of the data (*.RSSPEC) stored in the *.UNRST file. This keyword is somewhat redundant as the RESTART index file is written out by default. See the NORSSPEC keyword in the RUNSPEC section that deactivates the writing out of the file.

Hence, OPM Flow ignores this keyword. It is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE OUTPUT OF THE RESTART INDEX FILE *.RSSPEC
--
RSSPEC
```

The above example switches on the writing of the restart index file (*.RSSPEC); however, this has no effect in OPM Flow input decks.

5.3.124 RUNSPEC - DEFINE THE START OF THE RUNSPEC SECTION OF KEYWORDS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The RUNSPEC activation keyword marks the start of the RUNSPEC section that defines the key parameters for the simulator including the dimensions of the model, phases present in the model (oil, gas and water for example), number of tables for a given property and the maximum number of rows for each table, the maximum number of groups, wells and well completions, as well as various options to be invoked by OPM Flow.

Apart from COMMENTS entered by "--" in columns one and two, this keyword should be the first keyword in the input deck.

There is no data required for this keyword and there is no keyword terminating "/"

Example

```
-- ================================================================================
--
-- RUNSPEC SECTION
--
-- ================================================================================
RUNSPEC
```

The above example marks the start of the RUNSPEC section in the OPM Flow data input file.

5.3.125 SAMG – ACTIVATE ALGEBRAIC MULTI-GRID LINEAR SOLVER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword actives the algebraic multi-grid linear solve; note this solver is not available to the general public in the commercial simulator.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.

5.3.126 SATOPTS – ACTIVATE RELATIVE PERMEABILITY ASSIGNMENT OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SATOPTS keyword activates OPM Flow's relative permeability assignment options. The relative permeability functions are defined using the either the:

1) SWOF, SGOF, SLGOF series of saturation functions, or the
2) SWFN, SGFN, SGWFN, SOF2, SOF3, SOF32D series of functions.

The allocation of the relative permeability tables to the grid cells is dependent on the options selected on this keyword (SATOPTS).

If the DIRECT option as been activated and the IRREVERS has not been invoked on the SATOPTS keyword, then different relative permeability functions are used for each x, y, and z directions. Here the KRNUMX, KRNUMY and KRNUMZ keywords are used for Cartesian grids to allocate the relative permeability tables to the cells. For Radial grids the KRNUMR, KRNUMT and KRNUMZ keywords should be used. This results in the same relative permeability curves being used in both the xi to xi – 1 and the xi to xi + 1 flow directions. Similarly for the y direction the same curves are used for the yi to yi – 1 and the yi to yi + 1 flow directions. And again for the z direction, the same relative permeability function is used for flow in the zi to zi – 1 and the zi to zi + 1 flow directions.

If the DIRECT option as been activated and the IRREVERS has been invoked on the SATOPTS keyword, then KRNUMX, KRNUMY and KRNUMZ keywords are used for Cartesian grids to allocate the relative permeability tables in the xi to xi + 1, yi to yi + 1, zi to zi + 1, flow directions, respectively. For Radial grids the KRNUMR, KRNUMT and KRNUMZ keywords should be used. For flow in the xi to xi – 1 flow directions, etc., the KRNUMX-, KRNUMY- and KRNUMZ- keywords are used for Cartesian grids and the KRNUMR-, KRNUMT- and KRNUMZ- are used for radial grids.

The HYSTER option activates the relative permeability hysteresis option of the non-wetting phases (liquid and vapour) may show hysteretic behavior in that their values depend on whether the non-wetting phase saturation is increasing or decreasing. For this option the user specifies two sets of saturation functions, one for a drainage process (decreasing wetting phase saturation) and one for an imbibition process (increasing wetting phase saturation). For a process starting at the maximum wetting phase saturation, on the drainage curve, with the wetting phase saturation decreasing, the drainage curve is followed. Similarly for a process starting at the minimum wetting phase saturation with the wetting phase saturation increasing, the imbibition curve is followed. If the drainage or imbibition process is reversed at some point, then the data does not necessarily run back over its previous values. In OPM Flow the Carlson[103] is used to describe relative permeability hysteresis and the Killough[104] model is used for capillary pressure.

If the DIRECT option as been activated and the IRREVERS has not been invoked on the SATOPTS keyword, then the same set are keywords as for the DIRECT only option are used to assign the drainage relative permeability curves, that is: KRNUMX, KRNUMY, etc., plus the IMBNUMX, IMBNUMY, and IMBNUMZ, keywords for the imbibition curves. If the DIRECT option as been activated and the IRREVERS has been invoked on the SATOPTS keyword, then the same set are keywords as for the DIRECT and IRREVERS option are used to assign the drainage relative permeability curves, that is: KRNUMX, KRNUMX-, etc., plus the IMBNUMX, IMBNUMY, MBNUMZ, IMBNUMX-, IMBNUMY-, IMBNUMZ- keywords for the imbibition curves. See Table 5.40 for the various relative permeability table allocation keywords for the various combination of DIRECT, IRREVERS and HYSTER command options.

The keyword should be followed by one or more of the following keyword options.

[103] *Carlson, F. M. (1981) SPE 10157, presented at the 56th Annual SPE Fall Meeting, San Antonio, 1981*

[104] *Killough, J. E. "Reservoir Simulation with History-dependent Saturation Functions," paper SPE 5106, Society of Petroleum Engineers Journal (1976) 16, No. 1, 37-48.*

No.	Name	Description	Default
1	DIRECT	A character string that activates the directional relative permeability assignment option. If the DIRECT command is stated then directional relative permeability assignment is activated and different relative permeability function are assigned to the x, y and z directions. In this case the KRNUMX, KRNUMY and KRNUMZ keywords are used for Cartesian grids to allocate the relative permeability tables. For Radial grids the KRNUMR, KRNUMT and KRNUMZ keywords should be used.	None
2	IRREVERS	A character string the activates reversible directional relative permeability assignment option. If IRREVERS is stated then the relative permeability assignment is set to non-reversible and results in different sets of relative permeability tables being applied for flow from the xI to xI + 1 direction and the xI to the xI – 1 direction, for all directions (x, y, z). in this case the KRNUMX, KRNUMY and KRNUMZ keywords are used for Cartesian grids to allocate the relative permeability tables in the xi to xi + 1 flow directions etc. For Radial grids the KRNUMR, KRNUMT and KRNUMZ keywords should be used. For flow in the xi to xi – 1 flow directions, etc., the KRNUMX-, KRNUMY- and KRNUMZ- keywords are used for Cartesian grids and the KRNUMR-, KRNUMT- and KRNUMZ- are used for radial grids. Only the default option is supported by OPM Flow, that is non-reversible permeability tables are not supported.	None
3	HYSTER	A character string that activates the hysteresis option. If the HYSTER and DIRECT options have activated and the IRREVERS has not been invoked on the SATOPTS keyword, then different relative permeability functions are used for each x, y, and z directions and for the drainage and imbibition processes. Here the drainage relative permeability curves are allocated via the KRNUMX, KRNUMX and KRNUMZ keywords for Cartesian grids and the KRNUMR, KRNUMT and KRNUMZ keywords for radial grids. The imbibition relative permeability curves are allocated via the IMBNUMX, IMBNUMY and IMBNUMZ keywords for Cartesian grids and the IMBNUMR, IMBNUMT and IMBNUMZ keywords for radial grids. If the HYSTER, DIRECT and IRREVERS options have activated, then different relative permeability functions are used for each x, y, and z directions, flow direction and for the drainage and imbibition processes. Then in addition to aforementioned relative permeability curves allocation keywords for the xi to xi + 1 flow direction etc., the xi to xi – 1 flow directions keywords, KRNUMX-, KRNUMY- and KRNUMZ- are used for Cartesian grids and the KRNUMR-, KRNUMT- and KRNUMZ- are used for radial grids. The imbibition relative permeability curves are allocated via the IMBNUMX-, IMBNUMY- and IMBNUMZ keywords for Cartesian grids and the IMBNUMR, IMBNUMT and IMBNUMZ keywords for radial grids.	None

No.	Name	Description	Default
4	SURFTENS	A character string that activates the capillary pressure surface tension pressure dependency option. Only the default option is supported by OPM Flow, that is capillary pressure surface tension pressure dependency option is not supported.	None

Notes:

1) Note that the IRREVERS command can only been activated if the DIRECT command is activated at the same time. See Table 5.40 for the various relative permeability table allocation keywords.
2) The keyword is terminated by a "/".

Table 5.39: SATOPTS Keyword Description

For clarity the following table outlines the keywords that should be used in allocating the relative permeability tables for the various SATOPTS options.

Option	Cartesian		Radial	
DIRECT Flow in all directions	KRNUMX KRNUMY KRNUMZ		KRNUMR KRNUMT KRNUMZ	
DIRECT and IRREVERS Flow in the i to i +1 directions.	KRNUMX, KRNUMY KRNUMZ		KRNUMR KRNUMT KRNUMZ	
Flow in the i to i -1 directions.	KRNUMX- KRNUMY- KRNUMZ-		KRNUMR- KRNUMT- KRNUMZ-	
DIRECT and HYSTER Flow in all directions.	**Drainage** KRNUMX KRNUMY KRNUMZ	**Imbibition** IMBNUMX IMBNUMY IMBNUMZ	**Drainage** KRNUMR KRNUMT KRNUMZ	**Imbibition** IMBNUMR IMBNUMT IMBNUMZ
DIRECT, IRREVERS and HYSTER Flow in the i to i +1 directions.	**Drainage** KRNUMX KRNUMY KRNUMZ	**Imbibition** IMBNUMX IMBNUMY IMBNUMZ	**Drainage** KRNUMR KRNUMT KRNUMZ	**Imbibition** IMBNUMR IMBNUMT IMBNUMZ
Flow in the i to i -1 directions.	KRNUMX-, KRNUMY- KRNUMZ-	IMBNUMX- IMBNUMY- IMBNUMZ-	KRNUMR- KRNUMT- KRNUMZ-	IMBNUMR- IMBNUMT- IMBNUMZ-

Notes:

1) Note the drainage and imbibition classification is related to the wetting phase, that may be either oil or water; however, water is normally assumed in most cases but there are exceptions to this, especially for heavy oils.

2) Keywords colored orange indicate keywords that are not currently supported in OPM Flow.

Table 5.40: SATOPTS Relative Permeability Function Allocation Keywords

Examples

The first example actives the directional relative permeability assignment option only and hence the following keywords are used to allocate the relative permeability arrays for Cartesian grids: KRNUMX, KRNUMY, and KRNUMZ.

```
--
--       ACTIVATE RELATIVE PERMEABILITY ASSIGNMENT HYSTERESIS OPTIONS
--       DIRECTTIONAL(DIRECT) IRREVERSIBLE(IRREVERS) HYSTERESIS(HYSTER)
SATOPTS
         'DIRECT'                                                        /
```

The next example actives the directional irreversible relative permeability assignment options, and hence the following keywords are used to allocate the relative permeability arrays for Cartesian grids: KRNUMX, KRNUMY, KRNUMZ, KRNUMX-, KRNUMY- and KRNUMZ-.

```
--
--       ACTIVATE RELATIVE PERMEABILITY ASSIGNMENT HYSTERESIS OPTIONS
--       DIRECTTIONAL(DIRECT) IRREVERSIBLE(IRREVERS) HYSTERESIS(HYSTER)
SATOPTS
         'DIRECT'   'IRREVERS'                                           /
```

Finally, the last option invokes all three assignment options.

```
--
--       ACTIVATE RELATIVE PERMEABILITY ASSIGNMENT HYSTERESIS OPTIONS
--       DIRECTTIONAL(DIRECT) IRREVERSIBLE(IRREVERS) HYSTERESIS(HYSTER)
SATOPTS
         'DIRECT'   'IRREVERS'   'HYSTER'                                /
```

In this case the drainage relative permeability curves are allocated by the KRNUMX, KRNUMY, KRNUMZ, KRNUMX-, KRNUMY-, KRNUMZ- keywords, and the imbibition relative permeability curves are allocated by the IMBNUMX, IMBNUMY, IMBNUMZ, IMBNUMX-, IMBNUMY-, IMBNUMZ- keywords.

Note

This keyword activates how relative permeability curves are assigned in the model. The ENDSCALE keyword allows the end-point scaling also to vary with direction, flow direction and hysteresis process, resulting in a great deal of flexibility.

Whether or not all these features should be used though is another question.

5.3.127 SAVE – ACTIVATE OUTPUT OF A SAVE FILE FOR FAST RESTARTS

Description

This keyword activates output of a SAVE file for fast restarts which are read in by the LOAD keyword in the RUNSPEC section. No data is required for this keyword.

OPM Flow does not support the SAVE file format for fast restarts like the commercial simulator, but instead writes a standard RESTART file at the requested time step in the SCHEDULE section, which can then be used to restart the simulation at a given point in time via the RESTART keyword in the RUNSPEC section.

Example

The first example requests that a SAVE file be written out in the RUNSPEC section; however, OPM Flow will not write a RESTART record if the SAVE keyword is encountered in the RUNSPEC section.

```
-- ==================================================================================
--
-- RUNSPEC SECTION
--
-- ==================================================================================
RUNSPEC
--
--       WRITE OUT SAVE FILE FOR FAST RESTARTS
--
SAVE
```

The second example shows how the keyword is used in the SCHEDULE section.

```
-- ==================================================================================
--
-- SCHEDULE SECTION
--
-- ==================================================================================
SCHEDULE

-- ----------------------------------------------------------------------------------
-- SCHEDULE SECTION - 2020-01-01
-- ----------------------------------------------------------------------------------
RPTSCHED
          'WELLS=2'    'WELSPECS'    'CPU=2'     FIP=2'                          /

DATES
          1  APR   2021  /
/
--
--       WRITE OUT SAVE FILE FOR FAST RESTARTS
--
SAVE

DATES
          1  JLY   2021  /
          1  OCT   2021  /
/
```

Here OPM Flow will write out a RESTART file instead of a SAVE file at April 1st, 2021.

5.3.128 SCDPDIMS – DEFINE SCALE DEPOSITION AND DAMAGE TABLE DIMENSIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SCDPDIMS keyword defines the number of tables used in the Scale Deposition option and the maximum number of entries for the various tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	NTSCDP	NTSCDP is a positive integer that defines the number of SCDPTAB scale deposition tables used in the Scale Deposition option.	0
2	NPSCDP	NPSCDP is a positive integer that defines the maximum number of entries (or rows) in any one SCDPTAB scale deposition table defined in the input deck.	0
3	NTSCDA	NTSCDA is a positive integer that defines the number of SCDATAB scale damage tables used in the Scale Deposition option.	0
4	NPSCDA	NPSCDA is a positive integer that defines the maximum number of entries (or rows) in any one SCDATAB scale damage table defined in the input deck.	0
5	Not Used		1*
6	Not Used		1*
7	NTSCDE	NTSCDE is a positive integer that defines the number of SCDETAB karst aquifer dissolution tables used in the Scale Deposition option.	0
Notes: 1) The keyword is terminated by a "/".			

Table 5.41: SCDPDIMS Keyword Description

Example

```
--
--        NO.     MAX     NO.     MAX     NOT   NOT   NO.
--        NTSCDP  NPSCDP  NTSCDA  NPSCDA  USED  USED  NTSCDE
SCDPDIMS
          5       10      4       10      1*    1*    3                    /
```

The above example defines the number of SCDPTAB scale deposition tables to be five with a maximum number of rows for each table set to 10, the maximum number of SCDATAB scale damage tables to be four with a maximum number of 10 rows per table, and the maximum number of SCDETAB karst aquifer dissolution tables to be three.

5.3.129 SKIP – ACTIVATE SKIPPING OF ALL KEYWORDS AND INPUT DATA

The SKIP keyword turns on skipping of keywords until the ENDSKIP activation keyword is encountered. All keywords and between the SKIP and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP – Activate Skipping of All Keywords and Input Data* in the GLOBAL section for a full description.

5.3.130 SKIP100 – ACTIVATE SKIPPING OF BLACK-OIL KEYWORDS AND INPUT DATA

This keyword turns on skipping of black-oil keywords until the ENDSKIP activation keyword is encountered. All black-oil keywords between the SKIP100 and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP100 – Activate Skipping of Black-Oil Keywords and Input Data* in the GLOBAL section for a full description.

5.3.131 SKIP300 – ACTIVATE SKIPPING OF "COMPOSITIONAL" KEYWORDS AND INPUT DATA

Turns on skipping of "compositional" keywords until the ENDSKIP activation keyword is encountered. All "compositional" keywords between the SKIP300 and ENDSKIP keywords are ignored by OPM Flow.

See *Error: Reference source not found* in the GLOBAL section for a full description.

5.3.132 SMRYDIMS – DEFINE MAXIMUM NUMBER OF SUMMARY VECTORS TO BE WRITTEN

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SMRYDIMS keyword defines the maximum number of summary vectors to be written out to the SUMMARY file (*.SUMMARY).

OPM Flow uses dynamic memory allocation and therefore the keyword has no effect and is ignored by the simulator, but is documented here for completeness.

No.	Name	Description	Default
1	NSUMMX	A positive integer that defines the maximum number of summary vectors to be written out to the SUMMARY file (*.SUMMARY).	10000
Notes: 1) The keyword is terminated by a "/".			

Table 5.42: SMRYDIMS Keyword Description

Example

```
--
--       SET THE MAXIMUM NUMBER OF SUMMARY VECTORS THAT CAN BE WRITTEN OUT
--
SMRYDIMS
         10000                                                              /
```

The above example sets maximum number of summary vectors that can be written out to the SUMMARY file to the default value of 10,000; however, this has no effect in OPM Flow input decks.

5.3.133 SOLVDIMS – DEFINE PEBI GRID NESTED FACTORIZATION SOLVER DIMENSIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SOLVDIMS defines the unstructured Perpendicular Bisector ("PEBI")[105] and [106] grid nested factorization solver dimensions. This keyword is generated by an external pre-processing program for generating simulation grids.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[105] *Heinemann, Z.E. and Brand, C.W. 1988. Gridding Techniques in Reservoir Simulation. Proc., First Intl. Forum on Reservoir Simulation, Alpbach, Austria, 339.*

[106] *Heinemann, Z.E., Brand, C.W., Munka, M. et al. 1991. Modeling Reservoir Geometry With Irregular Grids. SPE Res Eng 6 (2): 225–232. SPE-18412-PA. http://dx.doi.org/10.2118/18412-PA*

5.3.134 SOLVENT – ACTIVATE THE SOLVENT PHASE IN THE MODEL

Description

This keyword indicates that the solvent phase is present in the model and to activate the four component solvent model for this run. In addition to this keyword, the oil, water and gases phases should also be declared for the run using the OIL, WATER and GAS keywords. The keyword will also invoke data input file checking to ensure that all the required Solvent phase input parameters are defined in the input deck.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       SOLVENT PHASE IS PRESENT IN THE RUN
--
SOLVENT
```

The above example declares that the solvent phase is active in the model.

5.3.135 SPIDER – SPIDER GRID ACTIVATION OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SPIDER activates the OPM Flow spider grid geometry option for the model, if this keyword and the RADIAL keyword are omitted then Cartesian geometry is assumed by OPM Flow. Note that is an OPM Flow specific keyword and option.

Spider Grids basically take the standard radial geometry keywords in the grid section and transform the grid specification to an Irregular Corner-Point Grid which can then be viewed in OPM ResInsight in a more intuitive form. The only difference is that in the RUNSPEC section the SPIDER keyword is used instead of the RADIAL keyword. One drawback of the approach that only "cake-slides" can be used for Spider Grids; that is theta must be less than 360 degrees and the dimension must be one, not the full radial geometry.

See also the RADIAL keyword in the RUNSPEC section (*RADIAL – Radial Grid Activation Option*). Both Spider and Radial grids will be displayed the same in OPM ResInsight, as they both use Irregular Corner-Point Grid geometry. The difference is that the radial model's pore volumes are adjusted to match the radial geometry pore volumes, whereas, the Spider grid volumes are not adjusted. See the examples in the section on Radial Grids (*Radial Grids*) and Spider Grids (*Spider Grids*) for further information

Example

```
--
--       DEFINE SPIDER GRID GEOMETRY (OPM FLOW RADIAL GRID KEYWORD)
--
SPIDER
```

The above example actives OPM Flow's spider grid geometry option.

5.3.136 START – SIMULATION START DATE

Description

This keyword sets the start date for the simulation switches. If the DATES keyword is to be used during the simulation, then a start date should be entered.

No.	Name	Description	Default
1	DAY	A positive integer that defines the day of the month, the value should be greater than or equal to one and less than or equal to 31.	None
2	MONTH	Character string for the month and should be one of the following 'JAN', 'FEB', 'MAR', 'APR', 'MAY', 'JUN', 'JUL' (or 'JLY'), 'AUG', 'SEP', 'OCT', 'NOV', or 'DEC'	None
3	YEAR	A positive four digit integer value of the start year, which must be specified fully by four digits, that is 1986.	None
Notes: 1) The keyword is terminated by a "/".			

Table 5.43: START Keyword Description

Example

```
--
--        DEFINE THE START DATE FOR THE RUN
--
START
          01 'JAN' 2014                                                  /
```

The above example sets the start date for the run to be January 1, 2014.

Note

Whenever possible it is a good idea to always set the start date to be at the beginning of the year as per the example. As like most simulators, OPM Flow reports are always stated at the number of days from the start date (and sometimes at a given date). If the start date is at the beginning of the year, then calculating the actual date is relatively straight forward and simple.

5.3.137 SURFACT – ACTIVATE THE SURFACTANT PHASE IN THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword indicates that the surfactant phase is present in the model and to activate the surfactant flooding model. The keyword will also invoke data input file checking to ensure that all the required surfactant phase input parameters are defined in the input deck. See also the SURFACTW keyword in the RUNSPEC section that actives the surfactant phase, but with the changes to the wettability option activated as well.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE THE SURFACTANT PHASE IN THE MODEL
--
SURFACT
```

The above example declares that the surfactant phase is active in the model.

5.3.138 SURFACTW – ACTIVATE THE SURFACTANT PHASE WITH WETTABILITY CHANGES IN THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword indicates that the surfactant phase is present in the model and to activate the surfactant flooding mode with Changes to Wettability option activated as well. The keyword will also invoke data input file checking to ensure that all the required surfactant phase input parameters are defined in the input deck. See also the SURFACT keyword in the RUNSPEC section that actives the surfactant phase only, that is without the Changes to the Wettability option.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE THE SURFACTANT PHASE WITH WETTABILITY CHANGES IN THE MODEL
--
SURFACTW
```

The above example declares that the surfactant phase is active in the model together with the wettability changes.

5.3.139 TABDIMS – DEFINE THE NUMBER OF TABLES AND THE TABLE DIMENSIONS

Description

The TABDIMS keyword defines the maximum number of tables for a given table type dataset and the maximum number of entries for the various tables. The commercial simulator combines both the black-oil and compositional simulator variables on this keyword; however, although all the parameters are explained below only the black-oil parameters are used by OPM Flow.

No.	Name	Description	Default
1	NTSFUN	A positive integer that defines the number of relative permeability table sets defined in the input deck. The tables are allocated to different parts of the grid by the SATNUM keyword.	1
2	NTPVT	A positive integer that defines the number of fluid property table sets defined in the input deck. The tables are allocated to different parts of the grid by the PVTNUM keyword.	1
3	NSSFUN	A positive integer that defines the maximum number of saturation entries in the relative permeability tables defined in the input deck.	20
4	NPPVT	A positive integer that defines the maximum number of pressure entries in the PVT tables.	20
5	NTFIP	A positive integer defining the maximum number of regions in the FIPNUM region array. Note that this parameter may also be set on the REGDIMS keyword as well. If NTFIP is set in both places then the maximum value is used.	1
6	NRPVT	A positive integer that defines the maximum number of Rs and Rv entries in the PVT tables. If the DISGAS and VAPOIL options have not been activated then this parameter is ignored.	20
7	NRVPVT	A positive integer that defines the maximum number of Rv entries in the PVT tables for the commercial compositional simulator.	20
8	NTENDP	A positive integer that defines the maximum number of saturation end-point depth tables. The end-point depth tables are used to re-scale the saturation tables as a function of depth as oppose to being a grid block property. NTENDP may also be specified on the ENDSCALE keyword, and if specified on both here and on the ENDSCALE keyword the maximum value of the two is used.	1
9	NMEOSR	A positive integer that defines the maximum number of reservoir equations of states for the commercial compositional simulator.	1
10	NMEOSS	A positive integer that defines the maximum number of separator or surface equations of states for the commercial compositional simulator.	1
11	MXNFLN	A positive integer defining the maximum number flux regions in the FLUXNUM region array. MXNFLN can also be defined on the REGDIMS keywords as well. If MXNFLX is defined both here and on the REGDIMS keyword then the maximum value of the two is used.	10

No.	Name	Description	Default
12	MXNTHR	A positive integer that defines the maximum number of thermal regions for the commercial compositional simulator.	1
13	NTROCC	A positive integer that defines the number of rock compressibility entries enter by the ROCK keyword defined in the input deck. The ROCK data is allocated to different parts of the grid by the either the PVTNUM or ROCKNUM keywords in the REGIONS section. If NTROCC is defaulted then the PVTNUM array will be used to allocate the ROCK keyword data to the grid blocks; whereas, if a value is entered then the ROCKNUM array will be used instead. See also the ROCKOPTS keyword in the PROPS section that can be used to redefine if the PVTNUM, ROCKNUM or SATNUM arrays should be employed to allocate the ROCK keyword data.	1*
14	MXNPMR	A positive integer that defines the maximum number of pressure maintenance regions for the commercial compositional simulator.	0
15	NTABKT	A positive integer that defines the maximum number of temperature dependent K-value tables for the when the thermal option is activated in the commercial compositional simulator.	0
16	NTALPHA	A positive integer that defines the maximum number of transport coefficient tables for the commercial compositional simulator.	0
17	NASPKA	A positive integer that defines the maximum number of maximum number of entries in the ASPKDAM keyword tables for the commercial compositional simulator.	10
18	MXRAWG	A positive integer that defines the maximum number of maximum number of entries in the ASPREWG keyword tables for the commercial compositional simulator.	10
19	MXRASO	A positive integer that defines the maximum number of pressure maintenance regions for the commercial compositional simulator.	10
20		Not Used	1*
21	MCASPP	A positive integer that defines the maximum number of column entries in the ASPPW2D keyword tables for the commercial compositional simulator.	5
22	MRASPP	A positive integer that defines the maximum number of row entries in the ASPPW2D keyword tables for the commercial compositional simulator.	5
23	MXRATF	A positive integer that defines the maximum number of entries in the ASPWETF table for the commercial compositional simulator.	5
24	MXNKVT	A positive integer that defines the maximum number of composition dependent K-value tables for the commercial compositional simulator.	0
25	RESVED	Not Used	1*

No.	Name	Description	Default
Notes: 1) Table sets are groups of keywords that need to be defined to complete a table set. For example if NTPVT is set to three, then there must be three PVTO tables and three PVTG tables to complete the three PVT data set. 2) The keyword is terminated by a "/".			

Table 5.44: TABDIMS Keyword Description

Example

```
--
--        NO.     NO.     MAX     MAX     MAX     MAX     E300
--        NTSFUN  NTPVT   NSSFUN  NPPVT   NTFIP   NRPVT   BLANK   NTEND
TABDIMS
          15      9       40      30      1*      1*      1*      1               /
```

The above example defines number of relative permeability tables to be 15 with a maximum number of rows for each table set to 40, and the number of PVT tables to be nine with a maximum number of 30 rows per table.

5.3.140 TEMP – ACTIVATE THE TEMPERATURE MODELING OPTION

Description

This keyword activates the temperature modeling option in the commercial simulator. There is no data required for this keyword.

The temperature option (TEMP keyword) and the thermal option (THERMAL keyword) are two separate modeling facilities in the commercial simulator, although some keywords can be used by both options, for example the RTEMP keyword. OPM Flow's thermal implementation is based on solving the energy equation fully coupled with the black-oil equations so the results are not directly equivalent to the commercial simulator's black-oil TEMP or compositional THERMAL formulations. To activate OPM Flow's thermal implementation use the THERMAL keyword in the RUNSPEC section.

OPM Flow treats the TEMP keyword as an alias for the THERMAL keyword, although it is recommended that the THERMAL keyword is used instead.

Example

```
--
--       ACTIVATE THE TEMPERATURE MODELING OPTION (NOT SUPPORTED BY OPM FLOW)
--
TEMP
```

The above example activates the temperature modeling option in the commercial simulator, however the keyword is treated as an alias for the THERMAL keyword by OPM Flow and activates OPM Flow's thermal option.

5.3.141 THERMAL– ACTIVATE THE THERMAL MODELING OPTION

Description

This keyword activates the thermal modeling option. There is no data required for this keyword. The energy black-oil implementation in OPM Flow is a mixture of the commercial simulators black-oil and the commercial simulators "compositional thermal" keywords, as well as some OPM Flow specific keywords.

The temperature option (TEMP keyword) and the thermal option (THERMAL keyword) are two separate modeling facilities in the commercial simulator, although some keywords can be used by both options, for example the RTEMP keyword. OPM Flow's thermal implementation is based on solving the energy equation fully coupled with the black-oil equations so the results are not directly equivalent to the commercial simulator's black-oil TEMP or compositional THERMAL formulations.

Keywords specifically associated with both OPM Flow's THERMAL and the commercial simulators TEMP and THERMAL options are listed in Table 5.45 for ease of reference.

Section	Keyword	Function	OPM Flow	Commercial	
			THERMAL MODEL	TEMP MODEL	THERMAL MODEL
RUNSPEC	ROCKDIMS	Thermal Rock Dimensions of Over and Underburden Rock Types			
	TEMP	Activate the Temperature Modeling Option	Alias for THERMAL		Black-Oil
	THERMAL	Activate the Thermal Modeling Option			
GRID	ROCKCON	Thermal Rock Over and Underburden Connection Data			
	ROCKPROP	Thermal Rock Over and Underburden Property Data			
	HEATCR	Rock Heat Capacity.			
	HEATCRT	Rock Heat Capacity Temperature.			
	THCGAS	Gas Phase Thermal Conductivity.			
	THCOIL	Oil Phase Thermal Conductivity.			
	THCONR	Thermal Conductivity of liquids and reservoir rock.			
	THCONSF	Thermal Conductivity of liquids and reservoir rock scaling factor applied to THCONR to account for gas saturation.			
	THCROCK	Rock Thermal Conductivity.			
	THCSOLID	Solid Phase Thermal Conductivity.			
	THCWATER	Water Thermal Conductivity.			

Section	Keyword	Function	OPM Flow	Commercial	
			THERMAL MODEL	TEMP MODEL	THERMAL MODEL
PROPS	HEATVAP	Thermal Oil Component Heat of Vaporization			
	GASDENT	Gas Density Temperature Coefficients (OPM Flow keyword).			
	GASJT	Gas Joule-Thomson Coefficient (OPM Flow keyword).			
	GASVISCT	Gas Viscosity versus Temperature Functions (OPM Flow black-oil keyword).			
	OILDENT	Oil Density Temperature Coefficients (OPM Flow keyword).			
	OILJT	Oil Joule-Thomson Coefficient (OPM Flow keyword).			
	OILVISCT	Oil Viscosity versus Temperature Functions (OPM Flow black-oil keyword).			
	RTEMP	Constant Initial Reservoir Temperature.			
	RTEMPA	Constant Initial Reservoir Temperature.			
	RTEMPVD	Initial Reservoir Temperature versus Depth.			
	SPECHA	Thermal Specific Heat of Oil Component			
	SPECHEAT	Specific Heat of Oil, Water and Gas			
	SPECROCK	Specific Heat of the Reservoir Rock			
	TEMPVD	Initial Reservoir Temperature versus Depth.			
	THANALB	Activate Thermal Analytic Water Density Option			
	THERMEX1	Liquid Components Thermal Expansion Coefficient			
	WATDENT	Oil Density Temperature Coefficients.			
	WATJT	Water Joule-Thomson Coefficient (OPM Flow keyword).			
	WATVISCT	Oil Viscosity versus Temperature Function.			
REGION	THERMNUM	Thermal Region Numbers.			
SOLUTION	RTEMP	Constant Initial Reservoir Temperature.			

Section	Keyword	Function	OPM Flow	Commercial	
			THERMAL MODEL	TEMP MODEL	THERMAL MODEL
	RTEMPA	Constant Initial Reservoir Temperature.			
	RTEMPVD	Initial Reservoir Temperature versus Depth.			
	TEMPI	Initial Reservoir Temperature for All Cells.			
	TEMPVD	Initial Reservoir Temperature versus Depth.			
SCHEDULE	WTEMP	Set An Injection Well's Fluid Temperature			
	WINJTEMP	Define Injection Fluid Thermal Properties			

Notes:

1) Cells colored green implies the keyword can be used with this model formulation.
2) Cells colored orange means the keyword is recognized by OPM Flow's parser but is ignored and not used by OPM Flow. The TEMP keyword is treated as an alias for the THERMAL keyword by OPM Flow, although it is recommended that the THERMAL keyword is used instead.
3) Cells colored red should not be used with this model formulation.
4) The list is focused on the OPM Flow implementation of the energy and black-oil formulation and therefore does not necessary include all the commercial simulator's compositional keywords.

Table 5.45: OPM Flow's THERMAL Option Associated Keywords

In thermal runs a producing well's bottom-hole temperature is calculated based on a weighted average of the temperature in the grid cell connections open to flow in the producing well, that is the reported bottom-hole temperature, TBHT, is calculated as:

$$T_{BHT} = \frac{\sum_{i=1}^{M} W_i T_i}{\sum_{i=1}^{M} W_i} \tag{5.1}$$

with

$$W_i = \sum_{p}^{N} \left(\rho^r_{pi}\right) \left(q^r_{pi}\right) C_p \tag{5.2}$$

The term $\left(\rho^r_{pi}\right) \left(q^r_{pi}\right) C_p$ is the energy rate density (J/(K s)) of phase p,

where:

N = number of phases,
M = number of open connections in the well,
i = the open connection index,
p = the phase index, oil, water and gas.
r = indicating that the parameter is evaluated at reservoir conditions,

T = temperature (K),
q = connection flow rate (m^3/s),
ρ = fluid density (kg/m^3), and
C = specific heat capacity ((J(K kg))
(see the SPECHEAT keyword in the PROPS section).

The current implementation makes use of the internal energy:

$$E_{pi} = C_p \cdot T_i \tag{5.3}$$

derived from the enthalpy, Hpi

$$E_{pi} = H_{pi} + \frac{P_{pi}}{\rho^r{}_{pi}} \tag{5.4}$$

where P_{pi} is connection grid block pressure of phase p.

The phase rates at surface conditions $\left(q^s{}_{p1}\right)$ are converted to reservoir in situ rates $\left(q^r{}_{p1}\right)$ using the phase formation volume factor, Bpi, via:

$$q^r{}_{pi} = \frac{q^s{}_{pi}}{B^{-1}{}_{pi}} \tag{5.5}$$

And thus equation (5.2) can be simplified to:

$$W_i = \sum_p^N \left(\rho^r{}_{pi}\right) \left(\frac{q^s{}_{pi}\, E_{pi}}{B^{-1}{}_{pi} \cdot T_i}\right) \tag{5.6}$$

Example

```
--
--       ACTIVATE THE THERMAL MODELING OPTION (OPM FLOW THERMAL OPTION ONLY)
--
THERMAL
```

The above example activates the thermal modeling option.

5.3.142 TITLE – DEFINE THE TITLE FOR THE INPUT DECK

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The TITLE keyword defines the title for the input deck. The title text will be printed on all reports so as to act as a reference for the run.

No.	Name	Description	Default
1	TITLE	A character string that defines the TITLE for the input deck	None

Notes:

1) All the characters on the line are processed as a string and therefore there is no need to enclose the TITLE in quotes.
2) There is no terminator "/" for the keyword.

Table 5.46: TITLE Keyword Description

Note

It is good practice to include the name of the input file in the tittle (without the extension) for when cross checking results from multiple cases.

Example

```
--
--       DEFINE THE TITLE FOR THE RUN
TITLE
SPE01-THEM01-OPM1810-R01 - OPM THERMAL OPTION RUN
```

The above example defines the title for the run to be "SPE01-THEM01-OPM1810-R01 - OPM THERMAL OPTION RUN".

5.3.143 TRACERS – ACTIVATE TRACER OPTIONS AND SET TRACER ARRAY DIMENSIONS

Description

The TRACERS keyword defines the number of tracers in the model and the various passive tracer tracking options.

No.	Name	Description	Default
1	MXOILTR	A positive integer defining the maximum number of passive oil tracers defined using the TRACER keyword.	0
2	MXWATTR	A positive integer defining the maximum number of passive water tracers defined using the TRACER keyword.	0
3	MXGASTR	A positive integer defining the maximum number of passive gas tracers defined using the TRACER keyword.	0
4	MXENVTR	A positive integer defining the maximum number of passive environmental tracers defined using the TRACER keyword. Environmental tracers are used with the Environment Tracer model that takes into account tracer adsorption and decay. Only the default value of zero is currently supported.	0
5	DIFFOPT	A character string defining the numerical diffusion option for tracer tracking runs that should be set to: 1) DIFF activates the numerical diffusion control options. 2) NODIFF deactivates the numerical diffusion control options. Only the default value of NODIFF is supported	NODIFF
6	MXITRTR	A positive integer defining the maximum number of non-linear iterations to be used when the tracer option is activated.	12
7	MNITRTR	A positive integer defining the minimum number of non-linear iterations to be used when the tracer option is activated.	1
8	NONLIN	A character string stating if passive tracers as should be linear (NO) or non-linear (YES). Only the default value of NO is supported.	No
9	LNCONFAC	A real value defining the initial linear convergence factor. The default value of 1* means the parameter will not be utilized.	1*
10	NLCONFAC	A real value defining the initial non-linear convergence factor. The default value of 1* means the parameter will not be utilized.	1*
11	CONFAC	A real value defining the LNCONFAC and NLCONFAC convergence factors to be used after the initial convergence factor has been applied.	1.0
12	NUMCONF	A positive integer defining the maximum number of times CONFAC can be used.	0

No.	Name	Description	Default
Notes: 1) The keyword is terminated by a "/".			

Table 5.47: TRACERS Keyword Description

See also the TRACER keyword in the PROPS section that defines the individual tracers.

Example

```
--
--       NO OIL  NO WAT  NO GAS  NO ENV  DIFF    MAX    MIN    TRACER
--       TRACERS TRACERS TRACERS TRACERS CONTL   NONLIN NONLIN NONLIN
TRACERS
         0       7       1       0      'NODIFF' 1*     1*     1*             /
```

The above example defines seven tracers in the water phase and one tracer in the gas phase.

5.3.144 TRPLPORO – ACTIVATE THE TRIPLE POROSITY MODEL OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The TRPLPORO keyword activates the Triple Porosity Model option that models matrix, fractures and vuggy porosity for carbonate reservoirs, and specifies the number of matrix porosity systems

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	TRPLPORO	A positive integer value that specifies the number of matrix porosity systems in the model. TRPLPORO should be set to either: 1) TRPLPORO set equal to 2, if the vugs are only connected to the fractures, so that the porosity system is matrix and connected vugs, or, 2) TRPLPORO set equal to 3, if the vugs are connected to the fractures and the matrix, so that the porosity system is matrix, connected vugs, and isolated vugs.	1
Notes: 1) The keyword is terminated by a "/".			

Table 5.48: TRPLPORO Keyword Description

Note the keyword cannot be used in conjunction with the NMATRIX keyword, which is also in the RUNSPEC section.

Example

```
--
--       TRPLPORO
--       OPTION
TRPLPORO
         3                                                    /
```

The above example activates the Triple Porosity Model option and specifies the porosity system is matrix, connected vugs, and isolated vugs.

5.3.145 UDADIMS – DEFINE THE DIMENSIONS OF THE USER DEFINED ARGUMENTS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the dimensions of the User Defined Arguments ("UDA") used by OPM Flow that can be applied to various connection, group, and well keywords in the SCHEDULE section. UDAs are defined by the UDQ keyword that is used to specify values to be constants, SUMMARY variables, as defined in SUMMARY section, or a formula using various mathematical functions together with constants and SUMMARY variables.

Although this keyword is read by OPM Flow and the ACTION and UDQ computational logic and calculations have been implemented, one should used caution using this facility as it may result in OPM Flow aborting.

No.	Name	Description	Default
1	NMUDA	NMUDA is a positive integer that defines the number of arguments in a SCHEDULE section keyword, that are replaced by numeric UDQ values.	0
2	IGNORED	Not used and should be defaulted.	1*
3	MXUDA	MXUDA is a positive integer that defines the maximum number of unique arguments in a keyword that are replaced by numeric UDA values. Note that MXUDA differs from NMUDA, for example: 1) If only the oil rate argument of, say the WCONPROD keyword is specified by a UDA, then both NMUDA and MXUDA equal one. 2) However, if a second WCONPROD uses a different UDA, then NMUDA equals two, but MXUDA would still be one. 3) Finally, if the same two distinct UDAs are used separately in two lines of WCONPROD data, then both NMUDA and MXUDA must be set to two. As MXUDA's default value is 100 then this only needs to be increased where the same UDA is used more than 100 times.	100
Notes: 1) The keyword is terminated by a "/".			

Table 5.49: UDADIMS Keyword Description

Note that OPM Flow has a more restricted UDQ feature set than the commercial simulator, so not all options and functions are currently available.

Example

```
--
--        USER DEFINED ARGUMENT DIMENSIONS
--        NO.      NOT      TOTAL
--        ARGS     USED     UDQ
UDADIMS
          10        1*      10                                          /
```

In the above example both NMUDA and MXUDA are set equal to ten.

5.3.146 UDQPARAM – DEFINE PARAMETERS FOR THE USER DEFINED QUANTITY FEATURE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the dimensions of the User Defined Arguments ("UDA") used by OPM Flow that can be applied to various connection, group, and well keywords in the SCHEDULE section. UDAs are defined by the UDQ keyword that is used to specify values to be constants, SUMMARY variables, as defined in SUMMARY section, or a formula using various mathematical functions together with constants and SUMMARY variables.

Although this keyword is read by OPM Flow and the ACTION and UDQ computational logic and calculations have been implemented, one should used caution using this facility as it may result in OPM Flow aborting.

No.	Name	Description	Default
1	RSEED	RSEED is a positive integer greater than zero that sets a new random number seed for use in the UDQ functions RANDN, RANDU RRNDN and RRNDU. See also the RSEED character variable on the UDQDIMS keyword in the RUNSPEC section to default the random number seed for a restart run. This feature is not supported by OPM Flow.	1
2	RANGE	RANGE is a real positive value greater than or equal to one and less than or equal to 1.0×10^{20}, that sets the absolute range for the user defined quantities. The default value of 1×10^{20} sets the range from -1×10^{20} to $+1 \times 10^{20}$.	1×10^{20}
3	DEFAULT	DEFAULT is real value that is the default numerical value given to undefined UDQ variables and should be in the same range as RANGE.	0.0
4	TOLUDQ	TOLUDQ a real positive number greater than zero and less than one that defines the tolerance used to determine if two real values are equal. Floating-point numbers (as implemented in computers) are never exact, one cannot compare floating point numbers for exact equality. Thus, TOLUDQ defines a tolerance. For example, the default value of 1 x 10-4 means that if the difference between two real values is less than 1 x 10-4 then the values are considered equal.	1 x 10-4
Notes: 1) The keyword is terminated by a "/".			

Table 5.50: UDQPARAM Keyword Description

Note that OPM Flow has a more restricted UDQ feature set than the commercial simulator, so not all options and functions are available.

Example

```
--
--        USER DEFINED DEFAULT VALUES
--        SEED    RANGE    UNDEFINED   COMPARISON
--        INTG    -AND+    VALUE       TOLERANCE
UDQPARAM
          1      1.0E20    0.0         1.0E-4                                  /
```

The example explicitly sets the default values for all four variables on the UDAPARAM keyword, namely the random seed to one, the range to 1 x 1020, the undefined UDQ variables to zero, and the comparison tolerance to 1.0 x 10-4.

5.3.147 UDQDIMS – DEFINE THE DIMENSIONS OF THE USER DEFINED UDQ FEATURE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the dimensions associated with the UDQ keyword used in OPM Flow to calculate various user defined values in the SCHEDULE section. The UDQ keyword defined variables can be constants, SUMMARY variables, as defined in the SUMMARY section, or a formula using various mathematical functions together with constants and SUMMARY variables.

Although this keyword is read by OPM Flow and the ACTION and UDQ computational logic and calculations have been implemented, one should used caution using this facility as it may result in OPM Flow aborting.

No.	Name	Description	Default
1	MXFUNS	A positive integer that defines the maximum number of functions that can be included when defining a UDQ definition. This should also include any brackets that will be used in the UDQ definition.	16
2	MXITEMS	MXITEMS is a positive integer that defines the maximum number of ITEMS allowed in an UDQ definition.	16
3	MXUDC	MXUDC is a positive integer that defines the maximum number of user defined CONNECTION quantities allowed in an UDQ definition.	0
4	MXUDF	MXUDF is a positive integer that defines the maximum number of user defined FIELD quantities allowed in an UDQ definition.	0
5	MXUDG	MXUDG is a positive integer that defines the maximum number of user defined GROUP quantities allowed in an UDQ definition.	0
6	MXUDR	MXUDR is a positive integer that defines the maximum number of user defined REGION quantities allowed in an UDQ definition.	0
7	MXUDS	MXUDS is a positive integer that defines the maximum number of user defined SEGMENT quantities allowed in an UDQ definition.	0
8	MXUDW	MXUDW is a positive integer that defines the maximum number of user defined WELL quantities allowed in an UDQ definition.	0
9	MXUDA	MXUDA is a positive integer that defines the maximum number of user defined AQUIFER quantities allowed in an UDQ definition.	0
10	MXUDB	MXUDB is a positive integer that defines the maximum number of user defined BLOCK quantities allowed in an UDQ definition.	0
11	RSEED	RSEED is a character string that determines if a new random number seed should be generated for restart runs for use in the UDQ functions RANDN, RANDU RRNDN and RRNDU. If RSEED is set to Y than a new seed will be generated and if set to the default value of N or 1* then the same seed of the "base" simulation will be employed. See also the RSEED integer variable on the UDQPARAM keyword in the RUNSPEC section to set the random number seed for the current run. This feature is not supported by OPM Flow.	N

No.	Name	Description	Default
Notes: 1) The keyword is terminated by a "/".			

Table 5.51: UDQDIMS Keyword Description

Note that OPM Flow has a more restricted UDQ feature set than the commercial simulator, so not all options and functions are available.

Example

```
--
--       USER DEFINED ARGUMENT DIMENSIONS FACILITY
--       MAX     MAX     MAX    MAX    MAX    MAX   MAX   MAX   MAX  MAX    RAND
--       FUNCS   ITEMS   CONNS  FIELD  GROUP  REGS  SEGTM WELL  AQUF BLCKS  OPT
UDQDIMS
         50      25      0      50     50     0     0     0     0    0      N  /
```

In this case the maximum number of functions that can be included when defining a UDQ definition is set to 50, maximum number of items allowed in an UDQ definition is 25, the maximum number of user defined field quantities allowed in an UDQ definition is 50, and the maximum number of user defined group quantities allowed in an UDQ definition is also 50. All other parameters are defaulted including the RSEED variable (the same seed of the "base" simulation will be employed).

5.3.148 UDTDIMS – DEFINE THE DIMENSIONS OF THE USER DEFINED TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the dimensions of the User Defined Tables ("UDT") used by OPM Flow that can be applied to various connection, group, and well keywords in the SCHEDULE section. UDAs are defined by the UDQ keyword that is used to specify values to be constants, SUMMARY variables, as defined in SUMMARY section, or a formula using various mathematical functions together with constants and SUMMARY variables.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description	Default
1	MXUDT	MXUDA is a positive integer that defines the maximum number of User Defined Tables	0
2	NUDT	NUDT is a positive integer that defines the maximum number of rows in any given User Defined Table.	0
3	MXINTP	MXINTP is a positive integer that defines the maximum number of interpolation points allowed in any given dimension.	0
4	MXDIMS	MXDIMS is a positive integer that defines the maximum number of dimensions in any given User Defined Table.	0

Notes:

1) The keyword is terminated by a "/".

Table 5.52: UDTDIMS Keyword Description

Example

```
--
--        USER DEFINED TABLE DIMENSIONS
--
--        MAX     MAX   MAX     MAX
--        TABLES  ROWS  INTPOL  DIMS
UDTDIMS
          3       20    3       2                                    /
```

In the above example the maximum number of UDT tables is set to three and the maximum number of rows for each table is 20, the maximum number of interpolation points in any given dimension is set to three and the maximum number of dimensions is defined as two.

5.3.149 UNCODHMD – ACTIVATE HISTORY MATCH GRADIENT UNENCODED OUTPUT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

UNCODHMD activates the history match gradient unencoded output for the history match gradient output file. Unencoded files allows external programs to read this file type.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE HISTORY MATCH GRADIENT UNENCODED OUTPUT
--
UNCODHMD
```

The above example switches on the unified output file option.

5.3.150 UNIFIN – ACTIVATE THE UNIFIED INPUT FILE OPTION

Description

This keyword switches on the Unified Input Files option for all input files. Similar to the commercial simulator, OPM Flow has various options for reading various input files and writing the resulting OPM Flow output files as described in Table 5.53.

Process	Keyword	Description	Files
Input	FMTIN	A character string that defines the input files to be formatted as ASCII i.e. text files, as oppose to binary files. The input deck file is always of this type. The option relates to the OPM Flow derived files that used as input, for for example when restarting from another case. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTIN	A character string that defines the input files to be non-unified multiple files, as opposed to unified files. In this case, one file is read in per reporting time step, as opposed to all time steps reports being read from one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001
	UNIFIN	A character string that defines the input files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. For this option a single summary file and a single restart file will be read. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY
Output	FMTOUT	A character string that sets all output files to be formatted as ASCII i.e. text files, as opposed to binary files. The *.PRT, *.LOG and *.DBG files are always of this type. The option relates to the OPM Flow output files only. In this case the files will be portable across operating systems, but will also be very large in terms of hard disk space. For this reason it is recommend that the default option is used so that binary files are outputted. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTOUT	A character string that defines the output files to be non-unified multiple files, as opposed to unified files. In this case, one file is written for each reporting time step, as opposed to all time steps reports being written in one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001

Process	Keyword	Description	Files
	UNIFOUT	A character string that defines the output files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. Here a single summary file and a single restart file will be generated, as opposed to one file per report time step. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY

Notes:

1) A binary file is computer-readable but not human-readable. All executable programs are stored in binary files, as are most numeric data files. In contrast, text files are stored in a form (usually ASCII) that is human-readable.
2) For unified files if the run terminates unexpectedly, or there is sufficient disk space, then the last report output is not stored. Their main advantage is that if a number of simulations reside in one directory, their output is organized. There is no limit on the number of reporting steps that a unified file can store.

Table 5.53: UNIFIN Keyword Description

There is no data required for this keyword and there is no terminating "/" for this keyword.

See also *OPM FLOW OUTPUT FILE FORMATS* for a more detailed description of the various file types (ASCII or binary) and file structure formats (unified or non-unified formats).

Example

```
--
--       SWITCH ON THE UNIFIED INPUT FILES OPTION
--
UNIFIN
```

The above example switches on the unified input file option.

5.3.151 UNIFOUT – ACTIVATE THE UNIFIED OUTPUT FILE OPTION

Description

This keyword switches on the Unified Output Files option for all output files. Similar to the commercial simulator, OPM Flow has various options for reading various input files and writing the resulting OPM Flow output files as described in Table 5.54.

Process	Keyword	Description	Files
Input	FMTIN	A character string that defines the input files to be formatted as ASCII i.e. text files, as oppose to binary files. The input deck file is always of this type. The option relates to the OPM Flow derived files that used as input, for for example when restarting from another case. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTIN	A character string that defines the input files to be non-unified multiple files, as opposed to unified files. In this case, one file is read in per reporting time step, as opposed to all time steps reports being read from one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001
	UNIFIN	A character string that defines the input files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. For this option a single summary file and a single restart file will be read. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY
Output	FMTOUT	A character string that sets all output files to be formatted as ASCII i.e. text files, as opposed to binary files. The *.PRT, *.LOG and *.DBG files are always of this type. The option relates to the OPM Flow output files only. In this case the files will be portable across operating systems, but will also be very large in terms of hard disk space. For this reason it is recommend that the default option is used so that binary files are outputted. If the keyword is omitted then the default is for binary file input.	*.FEGRID *.FINSPEC *.FINIT *.FRSSPEC *.FUNRST *.FSMSPEC *.FUNSMRY
	MULTOUT	A character string that defines the output files to be non-unified multiple files, as opposed to unified files. In this case, one file is written for each reporting time step, as opposed to all time steps reports being written in one file. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.X0001 *.SMSPEC *.S0001

Process	Keyword	Description	Files
	UNIFOUT	A character string that defines the output files to be unified files, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. Here a single summary file and a single restart file will be generated, as opposed to one file per report time step. If the keyword is omitted then the default is for one file per reporting time step.	*.RSSPEC *.UNRST *.SMSPEC *.UNSMRY

Notes:

1) A binary file is computer-readable but not human-readable. All executable programs are stored in binary files, as are most numeric data files. In contrast, text files are stored in a form (usually ASCII) that is human-readable.
2) For unified files if the run terminates unexpectedly, or there is sufficient disk space, then the last report output is not stored. Their main advantage is that if a number of simulations reside in one directory, their output is organized. There is no limit on the number of reporting steps that a unified file can store.

Table 5.54: UNIFOUT Keyword Description

There is no data required for this keyword and there is no terminating "/" for this keyword.

See also *OPM FLOW OUTPUT FILE FORMATS* for a more detailed description of the various file types (ASCII or binary) and file structure formats (unified or non-unified formats).

Example

```
--
--       SWITCH ON THE UNIFIED OUTPUT FILES OPTION
--
UNIFOUT
```

The above example switches on the unified output file option.

5.3.152 UNIFOUTS – ACTIVATE THE UNIFIED OUTPUT SUMMARY FILE OPTION

Description

The UNIFOUTS keyword causes the SUMMARY file output files to be a unified file, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. Here a single SUMMARY file will be generated, as opposed to one file per report time step. See also the MULTOUT keyword in the RUNSPEC section that sets both the SUMMARY and RESTART files to be non-unified multiple files, as opposed to unified files. Note also that UNIFOUTS keyword has precedence over the MULTOUT keyword for SUMMARY files.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--       ACTIVATE THE UNIFIED OUTPUT SUMMARY FILE OPTION
--
UNIFOUTS
```

The above example switches on writing of unified SUMMARY output files.

5.3.153 UNIFSAVE – ACTIVATE THE UNIFIED OUTPUT SAVE FILE OPTION

Description

The UNIFSAVE keyword causes the SAVE file output file to be a unified file, as opposed to non-unified multiple files. A unified file is a single file containing output for each reporting time step. Here a single SAVE file will be generated, as opposed to one file per report time step. See also the MULTOUT keyword in the RUNSPEC section that sets both the SUMMARY and RESTART files to be non-unified multiple files, as opposed to unified files.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--      ACTIVATE THE UNIFIED OUTPUT SAVE FILE OPTION
--
UNIFSAVE
```

The above example switches on writing of unified SAVE output files.

5.3.154 VAPOIL – ACTIVATE THE VAPORIZED OIL IN WET GAS PHASE IN THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword indicates that vaporized oil (more commonly referred to as condensate) is present in wet[107] gas in the model and the keyword should only be used if the there is both oil and gas phases in the model. The keyword may be used for gas-water and oil-water-gas input decks that contain the oil and gas phases. The keyword will also invoke data input file checking to ensure that all the required oil and gas phase input parameters are defined in the input deck.

If the gas has a constant and uniform vaporized oil concentration, Condensate-Gas Ratio ("CGR"), and if the reservoir pressure never drops below the saturation pressure (dew point pressure), then the model can be run more efficiently by omitting the OIL and VAPOIL keywords from the RUNSPEC section, treating the gas as a dry gas[108], and defining a constant Rv (CGR) value with keyword RVCONST or RVCONSTT in the PROPS section. This results in the model being run with as a dry gas problem with no active oil (condensate) phase. However, OPM Flow takes into account the constant Rv in the calculations and reporting.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       VAPORIZED OIL IN WET GAS IS PRESENT IN THE RUN
--
VAPOIL
```

The above example declares that the vaporized oil, i.e. condensate, in the gas phase is active in the model.

[107] *Natural gas that contains significant heavy hydrocarbons such as propane, butane and other liquid hydrocarbons is known as wet gas or rich gas. The general rule of thumb is if the gas contains less methane (typically less than 85% methane) and more ethane, and other more complex hydrocarbons, it is labeled as wet gas. Wet gas normally has GOR's less than 100,000 scf/stb or 18,000 Sm3/m3, with the condensate having a gravity greater than 50 °API.*

[108] *Natural gas that occurs in the absence of condensate or liquid hydrocarbons, or gas that had condensable hydrocarbons removed, is called dry gas. It is primarily methane with some intermediates. The hydrocarbon mixture is solely gas in the reservoir and there is no liquid (condensate surface liquid) formed either in the reservoir or at surface. The term dry indicates that the gas does not contain heavier hydrocarbons to form liquids at the surface conditions. Dry gas typically has GOR's greater than 100,000 scf/stb or 18,000 Sm3/m3.*

5.3.155 VAPWAT – ACTIVATE VAPORIZED WATER IN THE DRY AND WET GAS PHASES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword indicates that vaporized water is present in the gas phase and the keyword should only be used if both water and gas phases are present in the model. VAPWAT should also be used in conjunction with the PRECSALT keyword in the RUNSPEC section in order to activate OPM Flow's Salt Precipitation model. VAPWAT may be used for gas-water and oil-water-gas input decks that contain the oil, gas and water phases.

Note

This is an OPM Flow specific keyword for the simulator's Water Vaporization Model that is activated by declaring that vaporized water is present in the run.

Note that if the VAPWAT keyword is in the input deck then either the PVTGW or PVTGWO keywords in PROPS section should be used to defined the gas and water PVT properties.

Secondly, if both the VAPWAT keyword and the PRECSALT keyword (used to activate the OPM Flow's Salt Precipitation model) are present in the input deck, then the RWGSALT keyword in the PROPS section also needs to be present.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       VAPORIZED WATER IN DRY/WET GAS IS PRESENT IN THE RUN (OPM FLOW KEYWORD)
--
VAPWAT
```

The above example declares that the vaporized water is present in the gas phase and is active in the model.

5.3.156 VE – ACTIVATE VERTICAL EQUILIBRIUM MODEL (GLOBAL)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword actives the Vertical Equilibrium ("VE") model for the global grid and optionally specifies the type of VE model. The VE model type can either be compressed for merging columns of grid blocks into a single grid block, or uncompressed for the standard VE model.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.157 VFPIDIMS – INJECTION VERTICAL FLOW PERFORMANCE TABLE DIMENSIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

VFPIDIMS keyword defines the maximum dimensions of the injection well Vertical Lift Performance ("VFP") tables defined by VFPINJ keyword. The VFP tables for the producing wells are defined by the VFPPDIMS keyword.

No.	Name	Description	Default
1	MXMFLO	A positive integer that defines the maximum number of injection rate entries for the VFPINJ keyword.	0
2	MXMTHP	A positive integer that defines the maximum number of THP entries for the VFPINJ keyword.	0
3	MXVFPTAB	A positive integer that defines the maximum number of VFPINJ tables entered through the VFPINJ keyword.	0
Notes: 1) The keyword is terminated by a "/".			

Table 5.55:VFPIDIMS Keyword Description

Example

```
--       INJECTING VFP TABLES
--       VFP      VFP      VFP
--       MXMFLO   MXMTHP   NMMVFT
VFPIDIMS
         10       10       12                                        /
```

The above example defines that the maximum number of injection rates and THP entries on the VFPINJ keyword is 10, and the number of VFPINJ tables is 12.

5.3.158 VFPPDIMS – PRODUCTION VERTICAL FLOW PERFORMANCE TABLE DIMENSIONS

Description

VFPPDIMS keyword defines the maximum dimensions of the production well Vertical Lift Performance ("VFP") tables defined by VFPPROD keyword. The VFP tables for the injection wells are defined by the VFPIDIMS keyword.

No.	Name	Description	Default
1	MXMFLO	A positive integer that defines the maximum number of production flow rate entries for the VFPPROD keyword.	0
2	MXMTHP	A positive integer that defines the maximum number of THP entries for the VFPPROD keyword.	0
3	MXMWFR	A positive integer that defines the maximum number of water fraction entries (WOR, WCUT, GWR etc.) for the VFPPROD keyword.	0
4	MXMGFR	A positive integer that defines the maximum number of gas fraction entries (GOR, GLR, OGR etc.) for the VFPPROD keyword.	0
5	MXMALQ	A positive integer that defines the maximum number of artificial lift quantity entries for the VFPPROD keyword.	0
6	MXVFPTAB	A positive integer that defines the maximum number of VFPPROD tables entered through the VFPPROD keyword.	0

Notes:

1) The keyword is terminated by a "/".

Table 5.56: VFPPDIMS Keyword Description

Example

```
--        PRODUCING VFP TABLES
--        VFP      VFP      VFP      VFP      VFP      VFP
--        MXMFLO   MXMTHP   MXMWFR   MXMGFR   MXMALQ   NMMVFT
VFPPDIMS
          20       10       10       10       6        9                    /
```

Here the example shows that there are a maximum of 20 flow rates, 10 THP entries, 10 water and gas fraction entries, and six artificial lift entries for the nine VFPPROD VFP production tables.

5.3.159 VISAGE - ACTIVATE EXTERNAL RESERVOIR GEO-MECHANICS VISAGE OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The VISAGE keyword activates the External Reservoir Geo-Mechanics VISAGE option. The keyword should not be used in input decks as the associated data is generated by an external program.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

5.3.160 VISCD – ACTIVATE DUAL POROSITY VISCOUS DISPLACEMENT OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The VISCD keyword activates the Dual Porosity Viscous Displacement option for dual porosity and dual permeability models, and therefore requires either the DUALPORO or DUALPERM keyword to be entered in the RUNSPEC section to activate either one of these options. The VISCD option is used to model the viscous displacement of fluids from the matrix by the fracture pressure gradient, for when the fracture system has a more moderate permeability, and flow to and from the matrix caused by the fracture pressure gradient acts as an additional production mechanism[109]. Normally this mechanism is ignored as the pressure gradient in the fracture system is small due to the very high permeability of the fracture system. See the LX, Lyand LZ keywords in the GRID section that define representative matrix grid block sizes.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE DUAL POROSITY VISCOUS DISPLACEMENT OPTION
--
VISCD
```

The above example activates the dual porosity viscous displacement option.

[109] *Gilman, J. R. and Kazemi, H. "Improved Calculation for Viscous and Gravity Displacement in Matrix Blocks in Dual-Porosity Simulators," paper SPE 16010 (includes a number of associated papers), Journal of Petroleum Technology (1988) 40, No. 1, 60-70.*

5.3.161 WARN – ACTIVATE WARNING MESSAGES

Turns on warning messages to be printed to the print file (*.PRT); note that this keyword is activated by default and can subsequently be switched off by the NOWARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN. OPM Flow always prints error messages.

See *WARN – Activate Warning Messages* in the GLOBAL section for a full description.

5.3.162 WATER – ACTIVATE THE WATER PHASE IN THE MODEL

Description

This keyword indicate that the water phase is present in the model and must be used for gas-water, oil-water, oil-water-gas input decks that contain the water phase. The keyword will also invoke data input file checking to ensure that all the required water phase input parameters are defined in the input deck.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       WATER PHASE IS PRESENT IN THE RUN
--
WATER
```

The above example declares that the water phase is active in the model.

5.3.163 WELLDIMS – DEFINE THE WELLS AND GROUP DIMENSIONS

Description

WELLDIMS defines various well and group dimensions for the run. The commercial simulator combines both the black-oil and compositional simulator variables on this keyword; however, although all the parameters are explained below only the black-oil parameters are used by OPM Flow.

No.	Name	Description	Default
1	MXWELS	A positive integer defining the maximum number of wells for this model.	0
2	MXCONS	A positive integer defining the maximum number of grid block connections per well for this model.	0
3	MXGRPS	A positive integer defining the maximum number of groups for this model.	0
4	MXGRPW	A positive integer defining the maximum number of wells that can belong to a group in the model and the maximum number of child groups in a group. Note that MXGRPW sets both the maximum number of wells in a group and the maximum number of child groups in a group. The former applies to groups that contain wells and the latter applies to groups that contain other groups. See also the GRUPTREE keyword in the SCHEDULE section to define group hierarchy.	0
5	MXSTAGE	A positive integer defining the maximum number of stages per separator for this model. This option is ignored by OPM Flow.	5
6	MXSTRMS	A positive integer defining the maximum number of well streams for this model. This option is ignored by OPM Flow.	10
7	MXMIXS	A positive integer defining the maximum number of mixtures for this model. This option is ignored by OPM Flow.	5
8	MXSEPS	A positive integer defining the maximum number of separators for this model. This option is ignored by OPM Flow.	4
9	MXCOMPS	A positive integer defining the maximum number of mixture components in a mixture for the model. This option is ignored by OPM Flow.	3
10	MXDOCOMP	A positive integer defining the maximum number of well completions that can cross a parallel run domain boundary when the PARALLEL option has been activated. This option is ignored by OPM Flow.	0
11	MXWSLIST	A positive integer defining the maximum number of well lists that a well may be concurrent belong to at one time for this model. This option is ignored by OPM Flow.	1

No.	Name	Description	Default
12	MXWLISTS	A positive integer defining the maximum number of dynamic well lists for this model. This option is ignored by OPM Flow.	1
13	MXWSECD	A positive integer defining the maximum number of secondary wells for this model. This option is ignored by OPM Flow.	10
14	MXNGPP	A positive integer defining the maximum number of row entries per completion in the generalized pseudo-pressure tables used for to calculate the blocking factor associated with condensate drop-out in gas condensate reservoirs. If the generalized pseudo-pressure option has not been activated then this is ignored. This option is ignored by OPM Flow.	201

Notes:

1) Only parameters (1) to (4) are used by OPM Flow.
2) The keyword is terminated by a "/".

Table 5.57: WELLDIMS Keyword Description

Example

```
--
--       WELL    WELL    GRUPS   GRUPS
--       MXWELS  MXCONS  MXGRPS  MXGRPW
WELLDIMS
         60      110     18      40                                  /
```

The above example defines the maximum number of wells to be 60 with 110 completions per well, and maximum number of groups to be 18 with maximum number of wells per group of 40. All other parameters are defaulted.

5.3.164 WPOTCALC – WELL POTENTIAL CALCULATION OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

WPOTCALC defines how shut-in and stopped wells should have their well potentials calculated. Well potentials for wells under these conditions need to have their potentials calculated if they are in a Priority Drilling Queue via the WDRILPRI keyword in the SCHEDULE section, or the Prioritization option has been enabled by the PRIORITY keyword in the SCHEDULE section.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

5.3.165 WSEGDIMS – DEFINE MULTI-SEGMENT WELL DIMENSIONS

Description

The WSEGSDIMS keyword defines the multi-segment well dimensions for the multi-segment well model and the keyword is obligatory if multi-segment wells are being employed in the model.

No.	Name	Description	Default
1	MXWELS	A positive integer defining the maximum number of multi-segment wells for this model.	0
2	MXSEGS	A positive integer defining the maximum number of segments per well for this model.	1
3	MXBRAN	A positive integer defining the maximum number of branches per multi-segment well, including the main branch groups for this model.	1
4	MXLINKS	A positive integer defining the maximum number of segment links per multi-segment well. The simulator does not currently support multi-segment chord links, and therefore this parameter is ignored.	0
Notes: 1) The keyword is terminated by a "/".			

Table 5.58: WSEGDIMS Keyword Description

Example

```
--
--       WELL    WELL    BRANCH  SEGMENT
--       MXWELS  MXSEGS  MXBRAN  MXLINKS
WSEGDIMS
         5       100     10      10                                  /
```

The above example defines the maximum number of multi-segment wells to be five with up to 100 segments per multi-segment well, a maximum number of 10 branches per multi-segment well, and up to 10 segment links per multi-segment well.

CHAPTER 6: GRID SECTION

6.1 INTRODUCTION

The GRID section defines the basic grid properties, including structure, faults and various static rock properties (porosity, permeability etc.). The information in this section will be used by the software to calculate the pore volume (PORV) for each cell, the cell mid-point depths, and the regular transmissibilities (TRANX, TRANY and TRANX) between all the cells, as well as across faults. The OPM Flow calculated parameters can then be edited in the EDIT section.

All models can be classified by the number of dimensions as show in Figure 6.1 (after Mattax[110]). The zero and one dimension models are employed in analytical modeling, while the higher dimensions are used in numerical modeling. The term 4D modeling refers to a 3D model with the fourth dimension being the time domain derived from time-lapse seismic, that is the comparison of 3D seismic surveys at two or more points in time.

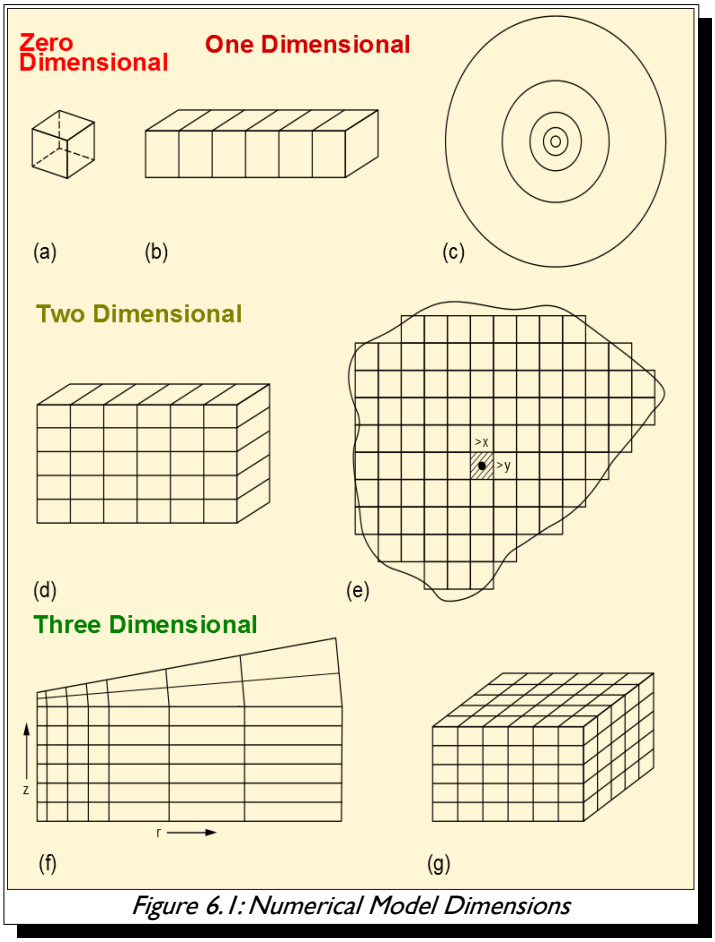

Figure 6.1: Numerical Model Dimensions

OPM Flow enables the user to define 1D, 2D and 3D models using three types of grids: Cartesian Regular Grid, Radial Grid[111], and Irregular Corner-Point Grids. The first two type of grids are rather limited in their ability to describe the structural complexity of oil and gas reservoirs; however, this simplicity allows the engineer to quickly build simple models to investigate reservoir performance. Indeed in the early days of numerical modeling back in the late 1970's two-dimensional cross-section and radial models were the main models used to predict reservoir performance due to limited computer resources at the time. That is not to say that full field models were not developed, but that these full field models were very coarse in comparison to what is designed and built today using static earth modeling software.

A brief introduction to the three types of grids and the data requirements to fully defined the structural element of the grid together with the rock properties necessary to complete the GRID section data requirements is outlined in the following section. This is then followed by the keyword definitions applicable to this section.

[110] *Mattax, C.C. and Dalton R.L. 1990. Reservoir Simulation. Society of Petroleum Engineers, Henry L. Doherty Series, Monograph Vol. 13*

[111] *Radial grids are not currently implemented in this version of OPM Flow, but is expected to be incorporated in a future release.*

6.2 DATA REQUIREMENTS

6.2.1 CARTESIAN REGULAR GRIDS

This type of grid defines a regular orthogonal grid based on defining the x, y and z dimensions of all the cells and is normally employed when a complex structural model is not required. Figure 6.2 shows the SPE Comparative Solution Project Number 1 ("SPE-CSP01") as documented by Odeh[112].

[112] *Odeh, A. "Comparison of Solutions to a Three Dimensional Black-Oil Reservoir Simulation Problem." JPT 33 (1981):13-25.*

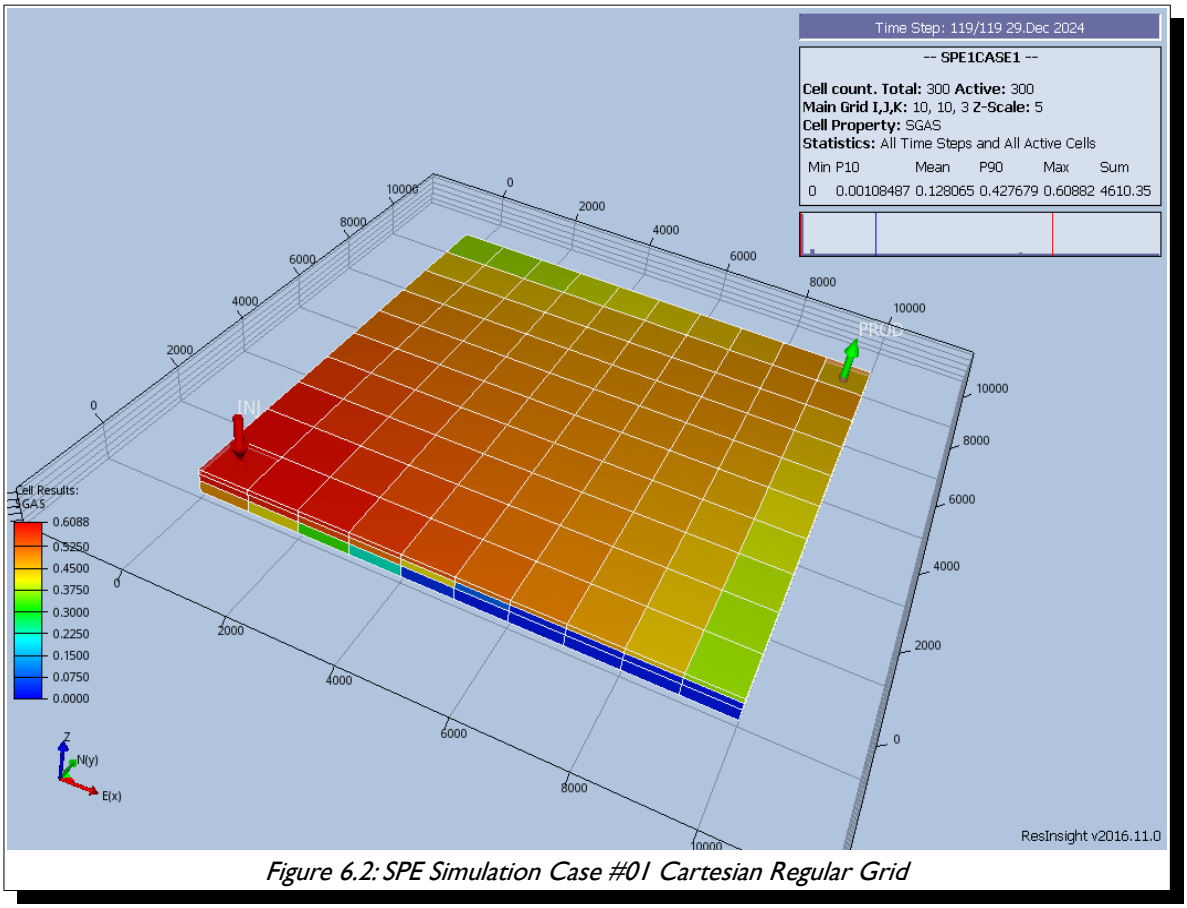

Figure 6.2: SPE Simulation Case #01 Cartesian Regular Grid

The model consists of a simple 10 x 10 x 3 (NX, NY, NZ) grid and is defined using the following GRID section keywords to define the grid geometry:

```
-- ================================================================================
--
-- GRID SECTION
--
-- ================================================================================
GRID
--
--       DEFINE GRID BLOCK SIZES IN THE X DIRECTION BASED ON NX x NY x NZ = 300)
--       (There Are In Total 300 Cells With Length 1000ft In X-Direction)
DX
         300*1000                                                              /
--
--       DEFINE GRID BLOCK SIZES IN THE Y DIRECTION (BASED ON NX x NY x NZ = 300)
--       (There Are In Total 300 Cells With Length 1000ft In Y-Direction)
DY
         300*1000                                                              /
--
--       DEFINE GRID BLOCK SIZES IN THE Z DIRECTION (BASED ON NX x NY x NZ = 300)
--
DZ
         100*20.0   100*30.0   100*50.0                                        /
--
--       DEFINE GRID BLOCK TOPS FOR THE TOP LAYER (BASED ON NX = 100, NY = 100)
--       (Layer 2 and 3 TOPS Calculated by Simulator)
TOPS
         25*3100  25*3105  25*3110                                             /
```

The rock property data required to complete the GRID section is as follows:

```
--
--      DEFINE POROSITY DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PORO
         300*0.300                                                             /
--
--      DEFINE PERMY DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PERMX
         100*500.0   100%50.0   100*200.0                                      /
--
--      DEFINE PERMY DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PERMY
         100*500.0   100%50.0   100*200.0                                      /
--
--      DEFINE PERMZ DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--      (Not Defined in Original Paper So Assume That PERMX = PERMY = PERMZ)
PERMZ
         100*500.0   100%50.0   100*200.0                                      /
```

The above keywords define all the properties required for the GRID section for this type of grid geometry.

6.2.2 IRREGULAR CORNER-POINT GRIDS

This type of grid is an industry standard grid used to formulate the structure of complex reservoirs [113]. Here static modeling software is used to build the model which is then exported and imported into a numerical model. Figure 6.3 illustrates the skeleton grid for the Norne Field which has dimensions of 46 x 112 x 22 in the x, y and z dimensions respectively. This results in a total number of cells of 113,344 although not all of these cells will be active in the model.

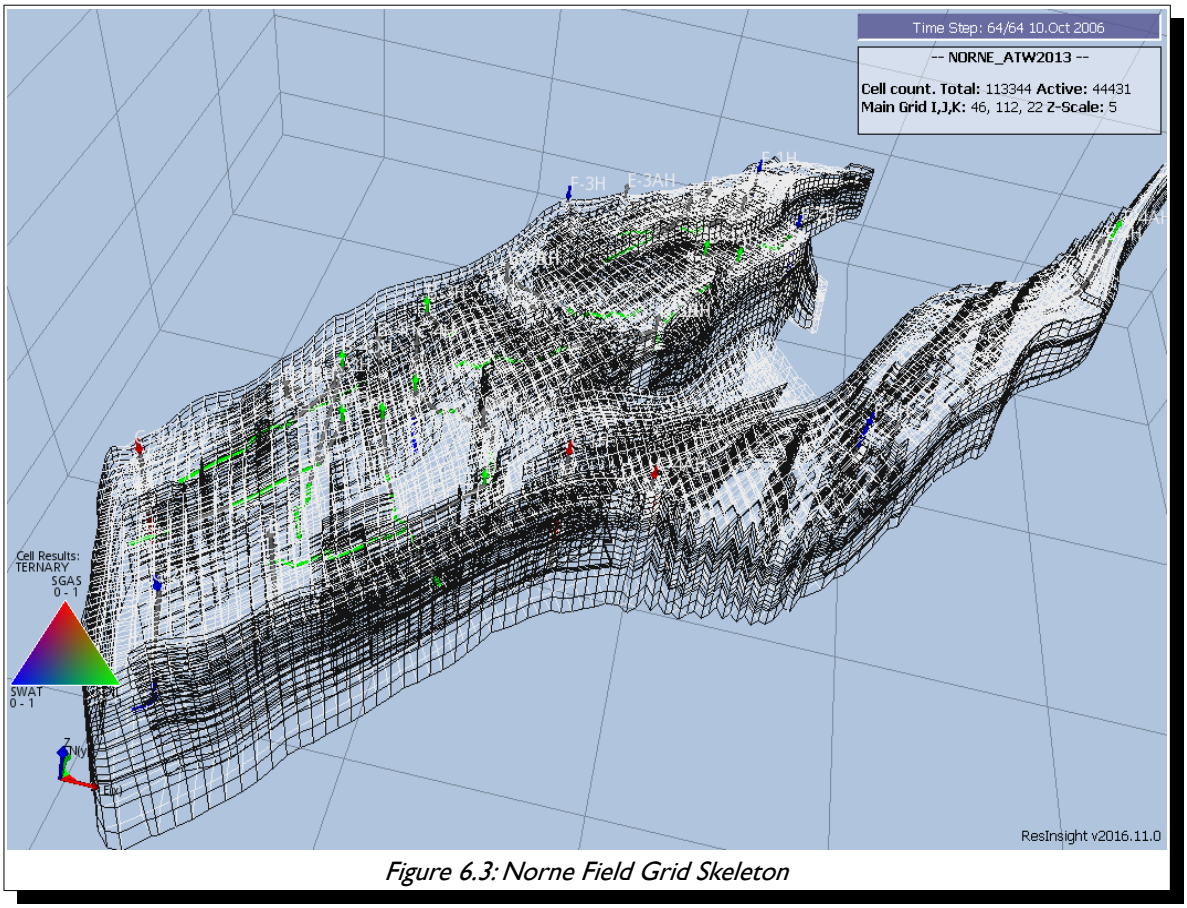

Figure 6.3: Norne Field Grid Skeleton

Similar to Cartesian Regular Grid the grid geometry must be defined for each cell and the properties for each cell defined. The formulation of the grid geometry is based on corner-point geometry, basically coordinate lines or pillars are given, then top and bottom surfaces for the cell are given by specifying the depth (z-coordinates) of the cell's corner points along each of the four adjacent pillars. The cell then forms an irregular hexahedron as depicted in Figure 6.4. Note that the figure shows a corner-point cell which is more or less orthogonal, which is ideally is what we want to minimize grid orientation effects.

The data required to define this type of grid consists of the SPECGRID to define the dimensions of the grid, that is:

```
--        MAX     MAX     MAX     MAX     GRID
--        NDIVIX  NDIVIY  NDIVIZ  NUMRES  TYPE
SPECGRID
          46      112     22      1       F                    /
```

[113] *K. Ponting, D, Corner Point Geometry in Reservoir Simulation, Conference Proceedings, ECMOR I - 1st European Conference on the Mathematics of Oil Recovery, Jul 1989, cp-234-00003 dDOI= "https://doi.org/10.3997/2214-4609.201411305", European Association of Geoscientists &; Engineers,*

A portion of the coordinate line data defined by the COORD keyword from the Norne model is shown on the next page.

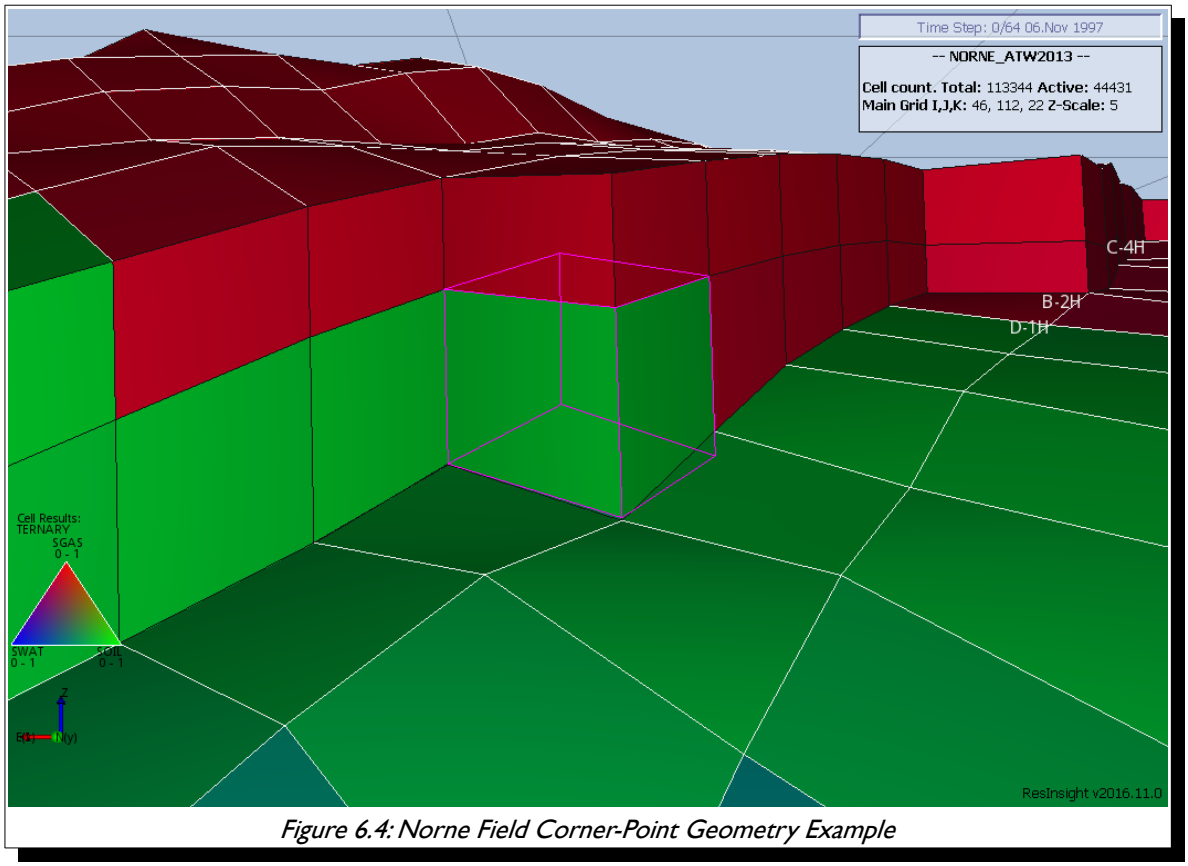

Figure 6.4: Norne Field Corner-Point Geometry Example

```

/
```

The rock property data required to complete the GRID section is the same as for a Cartesian Regular grid, as defined in section *6.2.1 Cartesian Regular Grids* and the data is defined using the same keywords. The resulting Norne model showing the ternary solution variable is displayed in Figure 6.5.

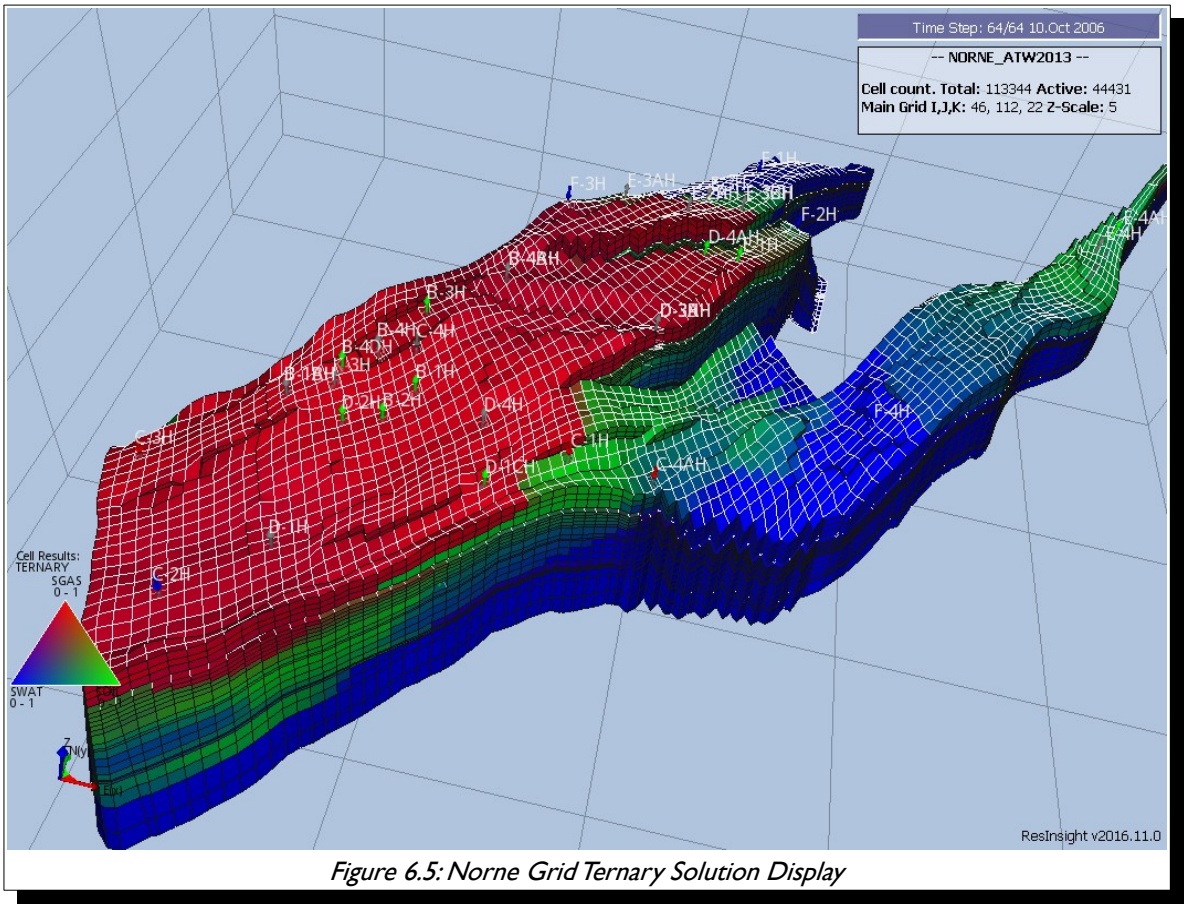

Figure 6.5: Norne Grid Ternary Solution Display

6.2.3 RADIAL GRIDS

Radial flow exists near the wellbore and linear or Cartesian flow occurs within the reservoir away from the wellbore. For field-wide studies the growth or decay of reservoir volumes activated by unsteady-state flow is small and hence linear flow is modeled via a linear grid, using either a Cartesian Regular Grid or an Irregular Corner-Point Grid, in these type of studies. On the other hand, for converging flow near wells the growth or decay of reservoir volumes activated by unsteady-state flow is large and radial flow should modeled. Thus, radial flow is important in only very localized areas around the wells and linear flow is modeled in most reservoir studies, for example in full field or sector models. Consequently for investigating near well bore effects, radial models are used to investigate the behavior around the wellbore, for example in gas cusping and water conning studies, as one can see from Figure 6.6.

In both Cartesian Regular and Irregular Corner-Point grids the dimension nomenclature is (x, y, z) for the x, y, and z planes. The corresponding nomenclature for Radial Grids is (r, theta and z) for r or radius plane, theta for the angular plane measured in degrees, and z for the z plane.

In Figure 6.6 the radial grid has been labeled as a 2-D Cylindrical grid because there is no flow in the theta direction only in the r and z planes, whereas the 3-D Reservoir grid in the figure has flow in both the x and y planes as well as the z plane. Figure 6.7 shows a typical 3-D radial grid with dimensions (10, 10, 3) in the (r, theta, z) dimensions taken from Odeh[114].

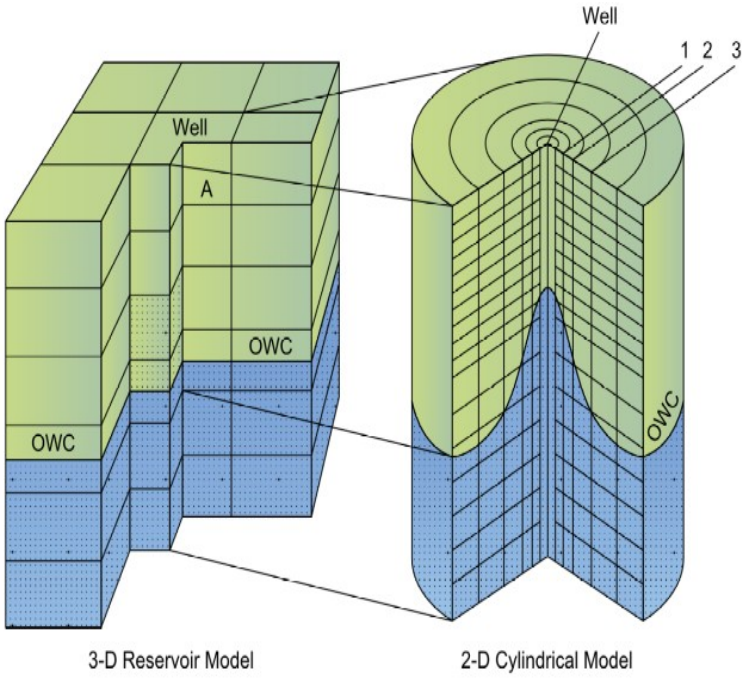

Figure 6.6: Cartesian and Radial Grids Comparison

Radial grids normally have a fine grid near the wellbore which then expands logarithmically away from the wellbore. This is illustrated in Figure 6.7 where one can clearly see the four most outer rings, but not the inner six. This type of grid makes solving the flow equations more challenging than conventional Cartesian and Irregular Corner-Point grids, were the cell pore volume distribution is relatively similar for neighboring cells, compared with Radial grids. For comparison, a typical conventional grid will have grid blocks size of 300, 300, 3 feet (or approximately 100m x 100m x 1m) spacing in the (x, y, z) plane; whereas a radial grid will utilize an inner most radius of between 0.25 to 1.0 foot in the R direction, and then logarithmically expand from the inner radius. The Odeh114 example employs 0.25 ft. for the inner radius, and 1.75, 2.32, 5.01, 10.84, 23.39, 50.55, 109.21, 235.92, 509.68, and 1101.08 ft. for the outer radii.

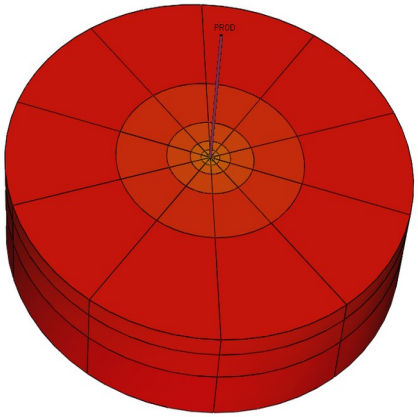

Figure 6.7: 3D Radial Grid (Odeh Example)

[114] *Comparison of Solutions to a Three-Dimensional Black-Oil Reservoir Simulation Problem by Aziz S. Odeh,-- Journal of Petroleum Technology, January 1981.*

Figure 6.7 is based on a 10 x 10 x 3 grid, where NX is the R dimensions, NY the THETA dimensions and NZ the z dimensions on the DIMENS keyword in the RUNSPEC section. Thus, in order to fully define this radial grid the following RUNSPEC and GRID section keywords are required:

```
-- ================================================================================
--
-- RUNSPEC SECTION
--

--
PERMTHT
         100*500.0    100*50.0    100*200.0                                    /
--
--         DEFINE GRID BLOCK Z DIRECTION CELL SIZE (BASED ON NX x NY x NZ = 300)
--
DZ
         100*500.0    100*50.0    100*200.0                                    /
```

The above keywords define all the properties required for the RUNSPEC and GRID sections for this type of grid geometry.

Note

Radial grids are currently not fully implemented in OPM Flow as the completion of the circle in the THETA direction is not supported. For reference only, this feature is activated via the COMPLETE parameter on the COORDSYS keyword in the GRID section.

OPM ResInsight is the 3D visualization software that is used to view the grid block property data and OPM Flow results (grid block pressures, fluid saturations etc.); unfortunately, the software does not render radial grids correctly, and currently there is no plan to implement this feature. Figure 6.8 shows how the Odeh[115] radial model is rendered in OPM ResInsight and this should be compared to Figure 6.7 which displays the correct rendering of the grid.

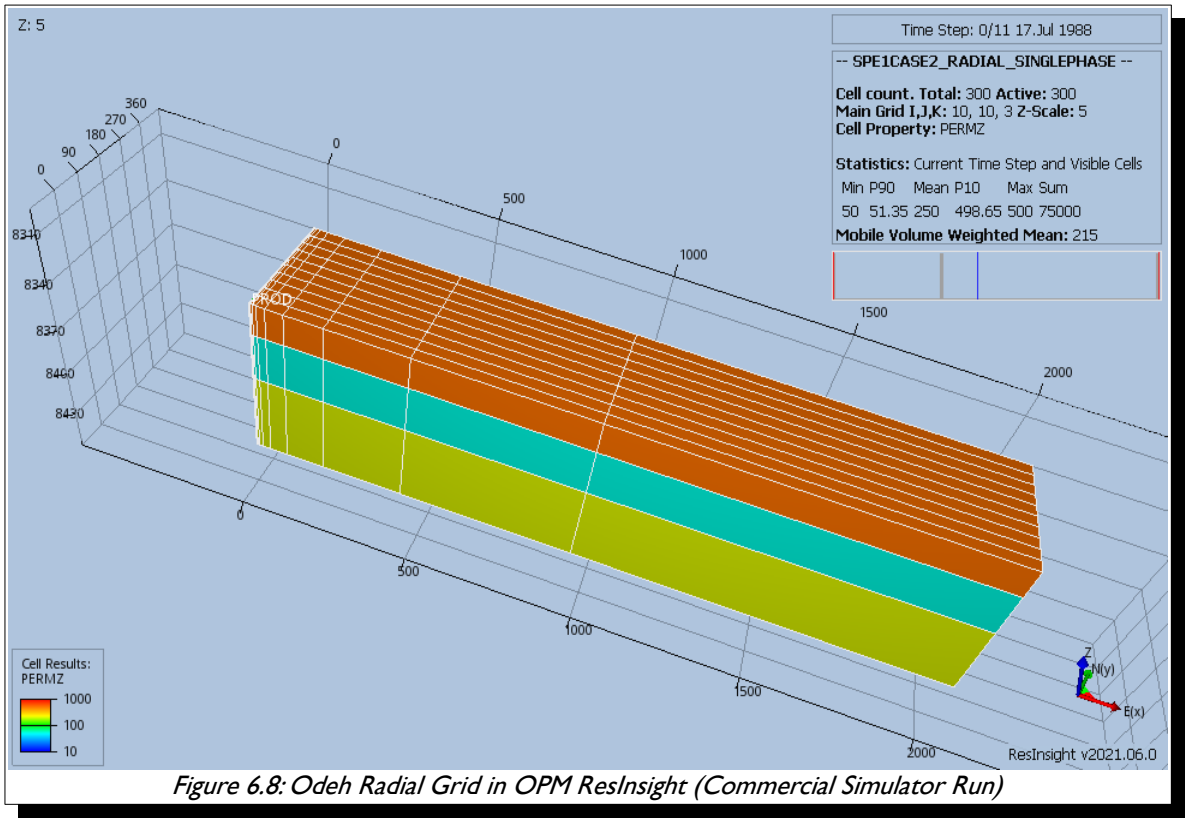

Figure 6.8: Odeh Radial Grid in OPM ResInsight (Commercial Simulator Run)

[115] *Comparison of Solutions to a Three-Dimensional Black-Oil Reservoir Simulation Problem by Aziz S. Odeh,-- Journal of Petroleum Technology, January 1981.*

The previous figure (Figure 6.8) shows how the model would be displayed if the commercial simulator run was loaded into OPM ResInsight. Previously, an OPM Flow run would also be displayed in the same manner.

To overcome this OPM ResInsight display limitation, OPM Flow now converts radial grids to Irregular Corner-Point Grids (Cartesian coordinates) and adjusts the model to reflect radial coordinates Thus, the OPM Flow radial model has the same pore volumes as the commercial simulator radial model.

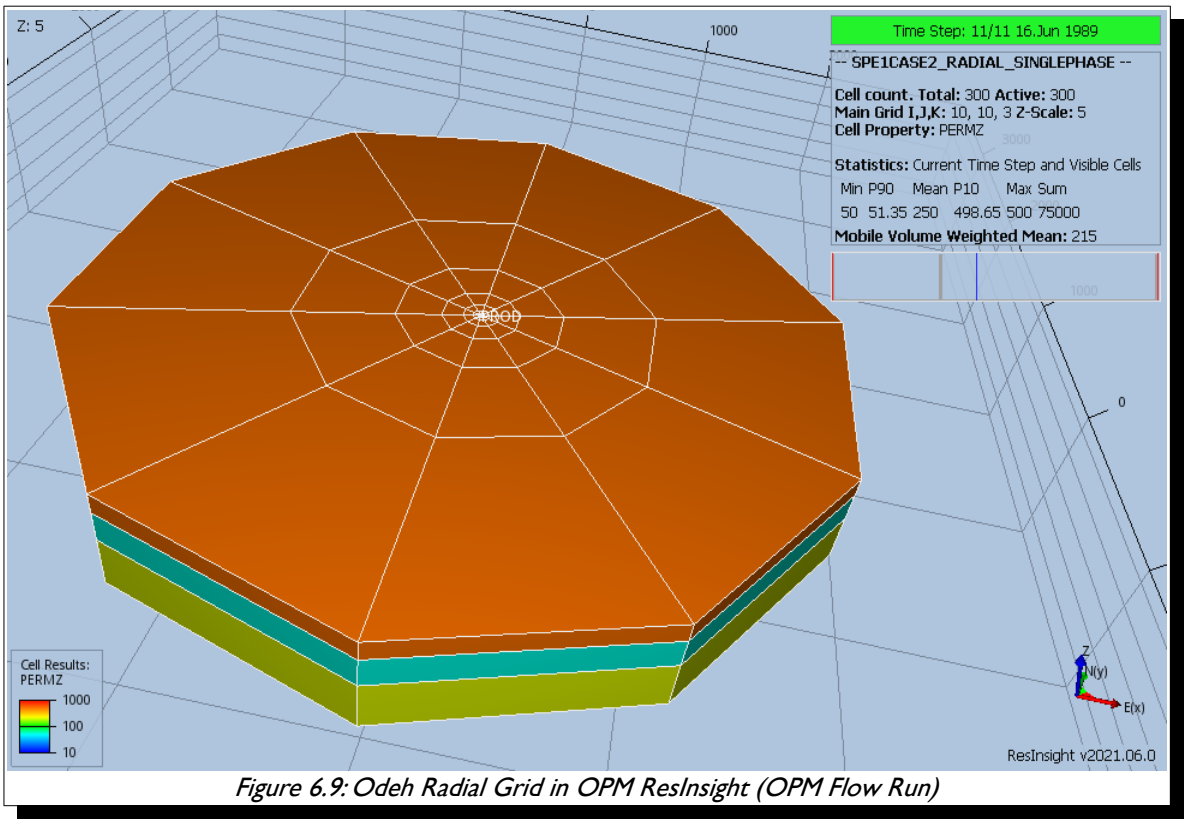

Figure 6.9: Odeh Radial Grid in OPM ResInsight (OPM Flow Run)

Figure 6.9 shows how the OPM Flow run is now displayed in OPM ResInsight. As will be shown in section 6.2.4 Spider Grids, both Spider and Radial grids will be displayed the same, as they both use Irregular Corner-Point Grid geometry. The difference is that the radial model's pore volumes are adjusted to match the radial geometry pore volumes, whereas, the Spider grid volumes are not adjusted.

6.2.4 SPIDER GRIDS

As mentioned in the previous section, OPM ResInsight does not render radial grids correctly and currently there is no plan to implement this feature. In order to overcome this limitation Spider Grids have been implemented that basically take the standard radial geometry keywords in the grid section and transform the grid specification to an Irregular Corner-Point Grid, which can then be viewed in OPM ResInsight in a more intuitive form. The only difference is that in the RUNSPEC section the SPIDER keyword is used instead of the RADIAL keyword.

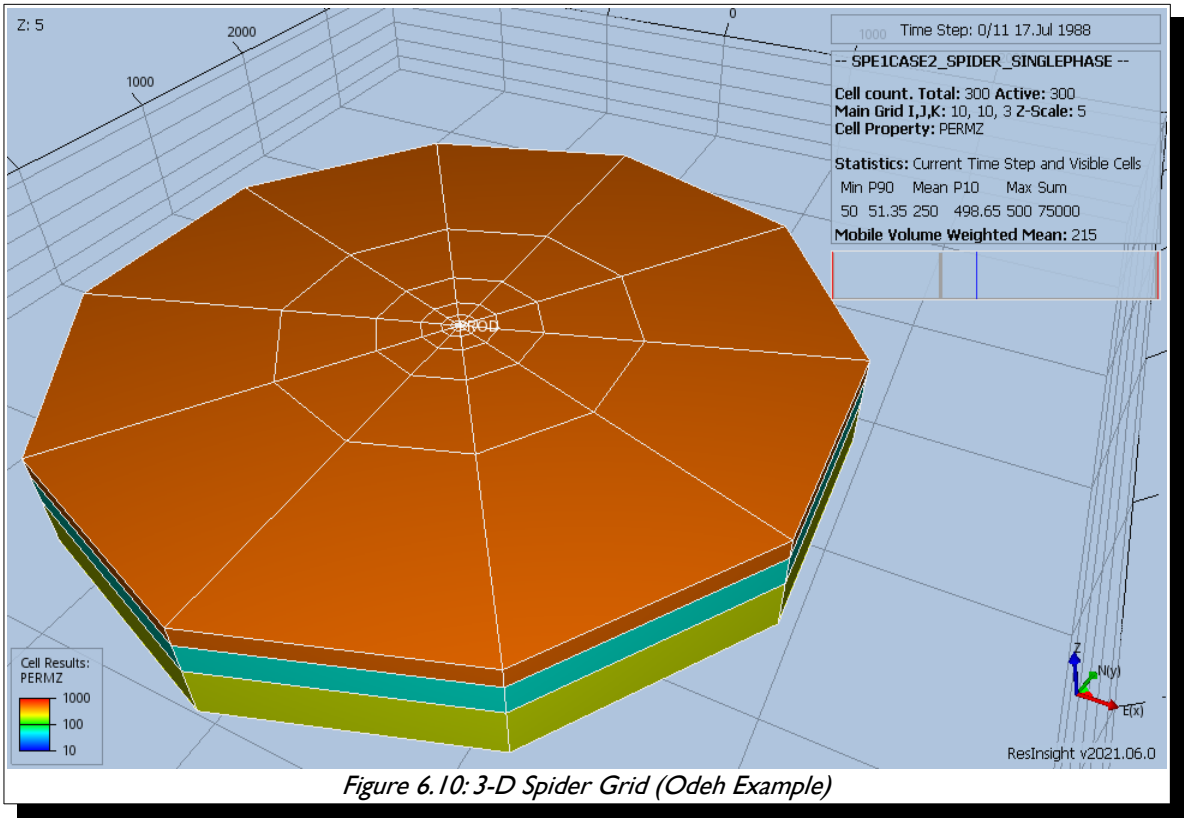

Figure 6.10: 3-D Spider Grid (Odeh Example)

Figure 6.10 illustrates the spider grid for the Odeh[115] example, which is not dissimilar to the conventional radial model shown in Figure 6.7 and is identical to OPM Flow's radial model implementation shown in Figure 6.9. Note that Figure 6.7 was not generated by OPM ResInsight,

Naturally, there will be differences in the results between radial and spider grid formulations, but the user should use their own judgement if the differences are relevant.

Again, Figure 6.10 is based on a 10 x 10 x 3 grid, where NX is the R dimensions, NY the THETA dimensions and NZ the z dimensions on the DIMENS keyword in the RUNSPEC section. The only difference between this example and the previous example for radial grids is that the RADIAL keyword has been replaced by the SPIDER keyword in the RUNSPEC section, all the other keywords are exactly the same.

```

The above keywords define all the properties required for the GRID section for this type of grid geometry.

6.2.5 ROCK PROPERTIES

Irrespective of the grid type used to define the structural component of the model various static properties need to be defined in order for the model to have a complete grid definition, these properties include the identification of active and inactive grid blocks, porosity, permeability, and the reservoir quality via the net-to-gross fraction ("NTG"). These parameters must be set for each cell in the model

Property	Description	Cartesian And Irregular Corner-Point Grids Keywords	Radial Grid Keywords
Active and Inactive cells	Defines if a cell in the model is active by setting the ACTNUM property for a cell to either one or inactive by setting the value to zero. Cells that are inactive in the model are ignored computationally and can act as barriers to flow. Thus, a shale in a conventional reservoir is normally treated as non-reservoir and is made inactive either by setting the ACTNUM, PORO, or NTG to zero for the cells representing the shale.	ACTNUM	
Porosity	Porosity is a measure of the space in a reservoir rock. It is defined as the fraction of the total bulk volume of the rock not occupied by solids, that is it is the fraction of the cell that is porous and contains the reservoir fluids.	PORO	
Reservoir Quality	Reservoir quality of the cell in terms of the gross volume derived from the structural grid and the net volume available for fluid flow in the model expressed as a fraction from zero to one. A zero values means the cell does contribute to flow and therefore is made inactive. A value of one means the gross and net volumes are identical for the cell	NTG	
Permeability	Permeability is a measure of the ease with which a fluid will flow through a porous medium. In numerical models permeability is dependent on the direction of flow, that is x, y and z directions in Cartesian and Irregular Corner-Point Grids, and the radial, theta and z directions in radial grids. There are various formulations for permeability, absolute permeability, effective permeability, gas permeability, liquid permeability etc., and the values are saturation dependent. Thus, values entered should be consistent with the relative permeability entered in the PROPS section. Normally Kair (Sg=1.0) should be entered for the cell permeability and the values may or not be corrected for overburden or humidity drying effects. Correcting for liquid flow and saturation end points etc., is accomplished by the relative permeability curves. For example, if Kair (Sg=1.0) has been entered for the cell permeability when Krg (Sg=1-Swc) should be less than one.	PERMX PERMY PERMZ	PERMR PERMTHT PERMZ

Table 6.1: Key Static Grid Properties

Note

Static grid properties are frequently generated from a static earth model using petrophysical evaluation of the well logs and propagated through the model based on a variety of geostatistical techniques.

Petrophysical evaluations are conducted in either in the "Total" or the "Effective" porosity domain, and is important that all the rock property data is entered into the model is of the same basis. It is not important which porosity domain is used, as long as all the data is in the same domain.

Pore volume and transmissibility are common terms in the reservoir simulation vernacular. Pore volume is self-explanatory, that is, given the grid property data the pore volume for each cell is calculated using:

$$PV = Cell\,Gross\,Volume \times PORO \times NTG \times ACTNUM \tag{6.1}$$

Where

PV	= the pore volume of a cell,
Cell Gross Volume	= the gross volume (or bulk volume) calculated from the structural parameters of the cell,
PORO	= cell porosity,
NTG	= cell net-to-gross ratio, and
ACTNUM	= active and inactive cell indicator.

Any cell with a pore volume equal to zero is made inactive automatically in the model. However, there may be some cells that have small pore volumes than may negatively impact computational performance of the model. If this is the case then the MINPV and MINPORV keywords in the GRID section can be used to make these cells inactive.

There has been a trend in the industry in recent years to not apply petrophysical cut-offs to determine net volumes in static models. This results in large models with numerous cells with very low porosity values (less than 0.01 for example) and corresponding very low permeabilities. The theory behind this approach is that the numerical model will determine the effective (or net) reservoir. However, the approach is questionable as by not applying net pay cut-offs, the in-place and recoverable volumes may not satisfy Reserve reporting requirements and guidelines to various agencies. Secondly, although this may be appropriate in unconventional reservoirs, as all the cells in the model will have similar values of porosity and permeability, but in conventional reservoirs this methodology will lead to severe computational issues when attempting to run the model, due to very tight cells being next to relative high permeability cells. Again, the MINPV and MINPORV keywords can be used to resolve this issue.

Transmissibility on the other hand is more complex as it relates the flow from one cell face to another cell face and is a function of the area open to flow, the direction of flow, the permeability, saturation and viscosity of the phases flowing between the cells. For a single phase flow in a Cartesian grid the x-direction transmissibility is of the form:

$$T_{x_{i+\frac{1}{2},\,j}} = \left[\frac{k_x\, h\,(\Delta y)}{\mu\,(\Delta x)}\right]_{i+\frac{1}{2},\,j} \tag{6.2}$$

As transmissibility is a property of the flow between two cell faces, not a block centered grid cell property like porosity or permeability, then the nomenclature for transmissibility is different. In OPM Flow, the transmissible of cell face $T_x(i, j, k)$ is the transmissibility between cells (i, j, k) and (i+1, j, k). In some simulators it would be between (i, j, k) and (i-1, j, k). This is important to note if manual modifications to cell connections are to be made in the model.

Modifications to basic grid property data, porosity and permeability etc., can only be done in the GRID section, thereafter only the calculated pore volumes and transmissibilities are available for adjustment in the EDIT section. Some engineers use the GRID section for the basic model formulation, and the EDIT section to document the changes to the "base" model using the PORV and TRANX, TRANY, TRANZ, etc. keywords.

6.3 KEYWORD DEFINITIONS

6.3.1 ACTNUM – SET THE STATUS OF A GRID BLOCK TO ACTIVE OR INACTIVE

Description

ACTNUM specifies which grid blocks are active or inactive. A value of 1 indicates the block is active and a value of 0 indicates the block is inactive. A grid block is inactive if its pore volume is less than the value entered using keyword MINPV. This keyword can be used to make blocks with a pore volume greater than MINPV inactive. Note that a value must be entered for each grid block in the model. Grid blocks are ordered with the I index cycling fastest, followed by the J and K indices. As for all array data repeat counts may be used, for example 100*1; however the full array must be specified.

Note that a cells activity can also be set using the EQUALS keyword by selection of only those cells that are required to be made inactive.

No.	Name	Description	Default
1	ACTNUM	An array of integers that define the activity of a cell by setting it to 1 for being active or 0 for inactive, for each grid block in the model.	1*

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX keyword..

2) The keyword is terminated by a "/".

Table 6.2:ACTNUM Keyword Description

Examples

The example below sets several cells to be inactive for a 4 x 5 x 2 model.

```
ACTNUM

0 0 1 1 # layer 1
0 0 1 1
1 1 1 1
1 1 1 1
1 1 1 1

1 1 1 1 # layer 2
1 1 1 1
1 1 1 1
1 1 1 1
0 0 0 0
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--        -- ARRAY    CONSTANT --  ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          'ACTNUM'    1.0000       1*  1*   1*  1*   1*  1* / SET ACTIVE CELLS
          'ACTNUM'    0.0000       1   2    1   2    1   1  / SET INACTIVE CELLS
          'ACTNUM'    0.0000       1   4    4   4    2   2  / SET INACTIVE CELLS
/
```

6.3.2 ADD – ADD A CONSTANT TO A SPECIFIED ARRAY

Description

The ADD keyword adds a constant to a specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the ADD keyword is being applied.

No.	Name	Description	Default
1	ARRAY	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	CONSTANT	An integer or real value to be added to the ARRAY in the same units as the ARRAY property.	0
3	I1	A positive integer that defines the lower bound of the array in the I-direction to be modified must be greater than or equal 1 and less than or equal to I2 and NX.	1
4	I2	A positive integer that defines the upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
5	J1	A positive integer that defines the lower bound of the array in the J-direction to be modified must be greater than or equal 1 and less than or equal to J2 and NY.	1
6	J2	A positive integer that defines the upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
7	K1	A positive integer that defines the lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
8	K2	A positive integer that defines the upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.3:ADD Keyword Description

The applicable arrays for each section are defined in Table 6.4 on the following page.

ADD Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Table 6.4:ADD Keyword Applicable Arrays by Section

Example

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                   I1  I2   J1  J2   K1  K2
ADD
          PERMX       20.000         1*  1*   1*  1*   1*  1* / ADD 20 mD TO PERMX
/
```

The above example ADDS 20 units to the PERMX array in the GRID section to all grid blocks in the model.

6.3.3 ADDREG – ADD A CONSTANT TO AN ARRAY BASED ON A REGION NUMBER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ADDREG keyword adds a constant to a specified array or part of an array based on cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the ADDREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the ADDREG keyword is being used.

No.	Name	Description	Default
1	ARRAY	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	CONSTANT	An integer or real value to be added to the ARRAY in the same units as the ARRAY property for a given REGION	0
3	REGION NUMBER	REGION NUMBER is a positive integer representing the region for which the CONSTANT in (2) should be applied	None
4	REGION ARRAY	The REGION ARRAY to use for applying the CONSTANT in (2) based on the REGION NUMBER in (3). REGION ARRAY can have the following values: 1) F for the FLUXNUM array 2) M for the MULTNUM array 3) O for the OPERNUM array	M

Notes:

1) Where the REGION NUMBER should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.5:ADDREG Keyword Description

The applicable arrays for each section are defined in Table 6.6.

ADDREG Keyword And Variable Options By Section

/
--
-       NOW RESET PORO AND PERMX BASED ON THE MULTNUM REGION NUMBER
--
--      ADD A CONSTANT TO AN ARRAY BASED ON A REGION NUMBER
--
--      ARRAY     CONSTANT  REGION   REGION ARRAY
--                VALUE     NUMBER    M / F / O
ADDREG
      PORO         0.050     1         M               /
      PORO         0.100     2         M               /
      PORO        -0.050     3         M               /
      PERMX        25.00     1         M               /
      PERMX        100.0     2         M               /
      PERMX       -50.00     3         M               /
/
```

The example first defines the PORO and PERMX property arrays for the model and then sets the MULTNUM array to 1 for all cells in the model, after which selected areas of model are assigned various MULTNUM integer values. The ADDREG can then be invoked to add or subtract constant values from the PORO and PERMX arrays for the various MULTNUM regions.

6.3.4 ADDZCORN – ADD A CONSTANT TO THE ZCORN DEPTH ARRAY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ADDZCORN keyword adds a constant to the ZCORN array or part of the array based on cells defined in the specified input box. The constant can be real or integer and can be negative or positive.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.5 AMALGAM – DEFINE LGR AMALGAMATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The AMALGAM keyword defines a Cartesian Local Grid Refinements ("LGR") amalgamations, that is merging several LGRs into one amalgamated LGR.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.6 AQUANCON – DEFINE ANALYTICAL CONNECTIONS TO THE GRID

Description

The AQUANCON keyword defines how analytical aquifers are connected to the simulation grid, this includes the Carter-Tracy, Fetkovich and Constant Flux analytical aquifers, all of which are implemented in OPM Flow. Carter-Tracy analytical aquifers are characterized by the AQUCT keyword in the GRID section and Fetkovich analytical aquifers are defined by the AQUFETP keyword in the SOLUTION section. Finally, the Constant Flux aquifer is defined by the AQUFLUX keyword in SOLUTION section.

Note that numerical aquifers are connected to the grid using the AQUCON keyword in the GRID section and that both aquifer types dimensions are declared by the AQUDIMS keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	AQUID	AQUID is a positive integer greater than or equal to one and less than the maximum number of analytical aquifers as defined by the NANAQU variable on the AQUDIMS keyword in the RUNSPEC section, that defines the aquifer to be connected to the grid.			None
2	I1	A positive integer that defines the lower bound of the cells in the I-direction to be connected to the aquifer and must be greater than or equal to one and less than or equal to I2 and NX.			1
3	I2	A positive integer that defines the upper bound of the of the cells in the I-direction to be connected to the aquifer and must be greater than or equal to I1 and less than or equal to NX			NX
4	J1	A positive integer that defines the lower bound of the cells in the J-direction to be connected to the aquifer and must be greater than or equal to one and less than or equal to J2 and NY.			1
5	J2	A positive integer that defines the upper bound of the cells in the J-direction to be connected to the aquifer and must be greater than or equal to J1 and less than or equal to NY.			NY
6	K1	A positive integer that defines the lower bound of the cells in the K-direction to be to be connected to the aquifer and must be greater than or equal to one and less than or equal to K2 and NZ.			1
7	K2	A positive integer that defines the upper bound of the cells in the K-direction to be connected to the aquifer and must be greater than or equal to K1 and less than or equal to NZ.			NZ
8	AQUFACE	AQUFACE is a character string that sets the connection "face" of the cells declared by this record and should be set to one of the following: 1) X+, Y+, or Z+ for the positive direction, or X-, Y- or Z- for the negative direction transmissibilities. 2) I+, J+, or K+ for the positive direction, or I-, J- or K- for the negative direction transmissibilities.			None
9	AQUFLUX	AQUFLUX is a positive real value that sets the fraction of the total influx between the aquifer and the defined cells declared on this keyword. If defaulted the cell face area for each cell is applied and if a value is declared then this value is applied to all cells declared by this record.			1*

No.	Name	Description			Default
		Field	Metric	Laboratory	
		ft^2	m^2	cm^2	
10	AQUCOEF	AQUCOEF is a real positive values that scales the calculated connection between the aquifer and the cells declared on this record.			
		dimensionless	dimensionless	dimensionless	1.0
11	AQUOPT	AQUOPT is a character string that sets the cell face connection and should be set to one of the following: 1) YES: Aquifer connections can adjoin to active cells allowing for connections inside the reservoir grid. It is not recommended to use this option without thoroughly checking the connections in the model. 2) NO: Aquifer connections cannot adjoin to active cells preventing connections inside the reservoir grid. This is the recommended and the default value.			NO

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.7: AQUANCON Keyword Description

Note

If the AQUANCON keyword has been utilized in the run deck then OPM Flow will write the AQUIFERA array to the *.INIT file in order to visualize the aquifer connections in OPM ResInsight.

This is accomplished by setting the AQUIFERA value to 2(AQUID-1) for cells connected to aquifer AQUID. If a cell is connected to multiple analytical aquifers then AQUIFERA is summed for all aquifers connected to a cell. Note that connecting cells to multiple aquifers is best avoided.

Example

The following example defines aquifer number one connected to the I+ face of various cells in the model.

```
--
--                      ANALYTIC AQUIFER CONNECTION
--
--       ID     ---------- BOX ---------    CONNECT  AQF    AQF      ADJOIN
--       NUMBER I1  I2   J1  J2   K1  K2    FACE     INFLX  MULTI    CELLS
AQUANCON
         1     57  57   28  36   46  58     'I+'    1*     1*       'NO'        /
         1    111 111   38  41   22  31     'I+'    1*     1*       'NO'        /
         1     96  96   44  49   22  31     'I+'    1*     1*       'NO'        /
         1     43  43   28  35   54  58     'I+'    1*     1*       'NO'        /
         1     98  98   38  42   32  40     'I+'    1*     1*       'NO'        /
         1     79  79   41  67    5  11     'I+'    1*     1*       'NO'        /
         1     61  61   48  72   12  17     'I+'    1*     1*       'NO'        /
/
```

See the AQUCT keyword in the GRID section for a complete example on defining and connecting a Carter-Tracy aquifer to a simulation grid.

6.3.7 AQUCON – DEFINE NUMERICAL AQUIFER CONNECTIONS TO THE GRID

Description

AQUCON keyword defines how numerical aquifers are connected to the simulation grid and these type of aquifers are characterized by the AQUNUM keyword in the GRID section. Analytical aquifers are connected to the simulation grid by the AQUANCON keyword in the GRID section, this includes the Carter-Tracy and Fetkovich analytical aquifers, both of which are implemented in OPM Flow. Both aquifer types dimensions are declared by the AQUDIMS keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	AQUID	AQUID is a positive integer greater than or equal to one and less than or equal to the maximum number of numerical aquifers as defined by the MXNAQN variable on the AQUDIMS keyword in the RUNSPEC section, that defines the aquifer to be connected to the grid.			None
2	I1	A positive integer that defines the lower bound of the cells in the I-direction to be connected to the aquifer and must be greater than or equal to one and less than or equal to I2 and NX.			1
3	I2	A positive integer that defines the upper bound of the of the cells in the I-direction to be connected to the aquifer and must be greater than or equal to I1 and less than or equal to NX			NX
4	J1	A positive integer that defines the lower bound of the cells in the J-direction to be connected to the aquifer and must be greater than or equal to one and less than or equal to J2 and NY.			1
5	J2	A positive integer that defines the upper bound of the cells in the J-direction to be connected to the aquifer and must be greater than or equal to J1 and less than or equal to NY.			NY
6	K1	A positive integer that defines the lower bound of the cells in the K-direction to be to be connected to the aquifer and must be greater than or equal to one and less than or equal to K2 and NZ.			1
7	K2	A positive integer that defines the upper bound of the cells in the K-direction to be connected to the aquifer and must be greater than or equal to K1 and less than or equal to NZ.			NZ
8	AQUFACE	AQUFACE is a character string that sets the connection "face" of the cells declared by this record and should be set to one of the following: 1) X+, Y+, or Z+ for the positive direction, or X-, Y- or Z- for the negative direction transmissibilities. 2) I+, J+, or K+ for the positive direction, or I-, J- or K- for the negative direction transmissibilities.			None

No.	Name	Description			Default
		Field	Metric	Laboratory	
9	AQUMULT	AQUMULT is a positive real number greater than or equal to zero that scales the OPM Flow calculated transmissibility between the AQUID aquifer and the grid cell connections defined by this record. The default value of one sets the transmissibility between the aquifer and grid cells to the OPM Flow calculated value.			
		dimensionless	dimensionless	dimensionless	1.0
10	AQUOPT1	AQUOPT1 is a defined integer value set to either zero or one, that defines the area to be used in calculating the connection transmissibility between the aquifer and the grid cells: 1) A value of zero means the cross-sectional defined on the AQUNUM keyword will be used, whereas, 2) A value of one means the cross-sectional defined by the grid cell connections defined by this record will be used.			
		dimensionless	dimensionless	dimensionless	0
11	AQUOPT2	AQUOPT2 is a character string that sets the cell face connection and should be set to one of the following: 1) YES: Aquifer connections can adjoin to active cells allowing for connections inside the reservoir grid. It is not recommended to use this option without thoroughly checking the connections in the model. 2) NO: Aquifer connections cannot adjoin to active cells preventing connections inside the reservoir grid. This is the recommended and the default value.			NO
12	VEOPT1	Vertical Equilibrium Option Number 1– Not Used			1
13	VEOPT2	Vertical Equilibrium Option Number 2– Not Used			1

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.8: AQUCON Keyword Description

Note

If the AQUCON keyword has been utilized in the run deck then OPM Flow will write the AQUIFERN array to the *.INIT file in order to visualize the aquifer connections in OPM ResInsight.

This is accomplished by setting the AQUIFERN value to 2(AQUID-1) for cells connected to aquifer AQUID. If a cell is connected to multiple numerical aquifers then AQUIFERN is summed for all aquifers connected to a cell. Note that connecting cells to multiple aquifers is best avoided.

Finally, for cells representing the numerical aquifers themselves, AQUIFERN is set to minus AQUID.

Example

The following example defines numerical aquifer number one connected to the I+ face of various cells in the model.

```
--
--        NUMERICAL AQUIFER CONNECTIONS
--
--       ID     ---------- BOX ---------    CONNECT  TRANS  TRANS  ADJOIN
--       NUMBER I1  I2   J1  J2   K1  K2    FACE     MULT   OPTN   CELLS
AQUCON
         1     57  57   28  36   46  58    'I+'     1*     1*     'NO'        /
         1    111 111   38  41   22  31    'I+'     1*     1*     'NO'        /
         1     96  96   44  49   22  31    'I+'     1*     1*     'NO'        /
         1     43  43   28  35   54  58    'I+'     1*     1*     'NO'        /
         1     98  98   38  42   32  40    'I+'     1*     1*     'NO'        /
         1     79  79   41  67    5  11    'I+'     1*     1*     'NO'        /
         1     61  61   48  72   12  17    'I+'     1*     1*     'NO'        /
/
```

See the AQUNUM keyword in the GRID section for a complete example on defining and connecting a numerical aquifer to a simulation grid.

6.3.8 AQUCT – DEFINE CARTER-TRACY ANALYTICAL AQUIFERS

Description

The AQUCT keyword defines Carter-Tracy[116] and [117] analytical aquifers, the properties of the aquifer, including the Carter-Tracy aquifer influence function associated with the aquifer, defined by the AQUTAB keyword in the PROPS section.

Each row entry in the AQUCT keyword defines one Carter-Tracy aquifer.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	AQUID	A positive integer greater than or equal to one and less than or equal to NANAQU on the AQUDIMS keyword in the RUNSPEC section, that defines the Carter-Tracy aquifer number.			1
2	DATUM	DATUM is a single positive value that defines the Carter-Tracy reference datum depth for PRESS.			
		feet	m	cm	None
3	PRESS	PRESS is a single positive value that defines the aquifer pressure at DATUM. If PRESS is defaulted then the simulator will set the aquifer's initial reservoir pressure to be in equilibrium with the cells the aquifer is contacted to.			
		psia	barsa	atma	1*
4	PERM	PERM is a real positive number that assigns the permeability to the aquifer.			
		mD	mD	mD	None
5	PORO	PORO is a real positive number greater than zero and less than or equal to one that assigns the porosity to the aquifer.			
		dimensionless	dimensionless	dimensionless	None
6	RCOMP	RCOMP is a real number defining the total (rock and water) compressibility (Ct) at the DATUM pressure.			
		1/psia	1/barsa	1/atma	None
7	RE	RE is a real positive number that defines the Carter-Tracy aquifer external radius.			
		feet	m	cm	None
8	DZ	DZ is a real positive number that defines the Carter-Tracy aquifer average net thickness.			
		feet	m	cm	None

[116] *Carter, R. D. and Tracy, G. W. "An Improved Method for Calculating Water Influx," Transactions of AIME (1960) 219, 215-417.*

[117] *Van Everdingen, A. & Hurst, W.,. The Application of the Laplace Transformation to Flow Problems in Reservoirs. Petroleum Transactions, AIME (December, 1949).*

No.	Name	Description			Default
		Field	Metric	Laboratory	
9	ANGLE	ANGLE is a real positive number that defines the angle of influence, that is the angular connection between the aquifer and the hydrocarbon reservoir. A value of 360° degrees, the default value, indicates that the aquifer completely surrounds the hydrocarbon reservoir.			
		degrees	degrees	degrees	360.0
10	PVTNUM	PVTNUM is positive integer greater than zero and less than the NTPVT variable on the TABDIMS keyword in the RUNSPEC section, that defines the PVTW table allocated to the Carter-Tracy aquifer.			1
11	AQUTAB	AQUTAB is positive integer greater than zero and less than the NIFTBL variable as declared on the AQUDIMS keyword in the RUNSPEC section, that defines the AQUTAB table allocated to this Carter-Tracy aquifer. The default value of one sets the internal infinite acting Carter-Tracy aquifer influence table not the first table in the AQUTAB keyword in the PROPS section The first table in the AQUTAB keyword is considered to be table number two. The internal table, AQUTAB equal to one, is based on the Radial Flow, Constant Pressure and Constant Terminal Rate Cases for Infinite Reservoirs (Table I) in Van Everdingen and Hurst's [118] paper.			1
12	SALTCON	SALTCON is a real positive number that defines the initial salt concentration in the aquifer, for when with simulator's Brine Model has been activated via the BRINE keyword in the RUNSPEC section. This variable is ignored by OPM Flow.			
		lb/stb	kg/sm^3	gm/scc	0.0
13	TEMP	TEMP is a real positive number that defines the initial temperature of the aquifer at DATUM for use with OPM Flow's thermal option. The THERMAL keyword in the RUNSPEC section must be activated to use this option.			
		°F	°C	°C	1*

Notes:

1) The keyword is followed by up to NANAQ records as defined on the AQUDIMS keyword in the RUNSPEC section
2) Each record is terminated by a "/" and the keyword should be terminated by a "/".

Table 6.9:AQUCT Keyword Description

Note

OPM Flow includes the infinite acting Carter-Tracy aquifer influence table as a default for table number one; thus data entered on AQUTAB keyword starts from table number two.

In order to full define a Carter-Tracy aquifer one has to define the aquifer properties via the AQUCT keyword, the Carter-Tracy influence function via the AQUTAB keyword in the PROPS section (*AQUTAB – Define Carter-Tracy Aquifer Influence Functions*), if the default infinite acting table is not being employed, and

[118] *Van Everdingen, A. & Hurst, W.,. The Application of the Laplace Transformation to Flow Problems in Reservoirs. Petroleum Transactions, AIME (December, 1949).*

finally, how the aquifer is connected to the reservoir using the AQUANCON keyword in the GRID or SOLUTION sections.

Example

Given the following grid and aquifer dimensions in the RUNSPEC section:

```
--
--       MAX     MAX     MAX
--       NDIVIX  NDIVIY  NDIVIZ
DIMENS
         20      1       5                                                    /

--       AQF     AQF     AQF     AQF     AQF     AQF     AQF     AQF
--       MXAQN   MXNAQC  NIFTBL  NRIFTB  NANAQU  NCAMAX  MXNALI  MXAAQL
AQUDIMS
         1*      1*      5       100     1       1*      1*      1*              /
```

And AQUTAB in the PROPS section

```
--
--       CARTER-TRACY AQUIFER INFLUENCE TABLES
--       (STARTS FROM TABLE NO. 2, AS DEFAULT IS TABLE NO. 1)
--
AQUTAB

          0.40         0.579
          0.42         0.593
          0.44         0.607
          0.46         0.621
          0.48         0.634
          0.50         0.648
          0.60         0.715
          0.70         0.782
          0.80         0.849
          0.90         0.915
          1.00         0.982
          2.00         1.649
          3.00         2.316
          5.00         3.649
         10.00         6.982
         20.00        13.649
         30.00        20.316
         50.00        33.649
        100.00        66.982
        200.00       133.649
```

```
        300.00      200.316
        500.00      333.649
       1000.00      666.982 /
```

The Carter-Tracy aquifer is defined in the GRID or SOLUTION sections as:

```
-- ================================================================================
--
-- SOLUTION SECTION
--
-- ================================================================================
SOLUTION
--
--                      CARTER-TRACY AQUIFER DESCRIPTION
--
--      ID   DATUM   AQF    AQF    AQF    AQF     AQF   AQF   INFL   PVT  AQU
--      NUM  DEPTH   PRESS  PERM   PORO   RCOMP   RE    DZ    ANGLE  NUM  TAB
--
AQUCT
         1   2000.0  269    100.0  0.30   3.0e-5  330   10.0  360.0   1    2   /
/
```

And the connection of the aquifer is set in the GRID or SOLUTION sections as:

```
--
--                      ANALYTIC AQUIFER CONNECTION
--
--       ID     ---------- BOX ---------   CONNECT  AQF    AQF      ADJOIN
--       NUMBER I1  I2   J1  J2   K1  K2   FACE     INFLX  MULTI    CELLS
AQUANCON
         1      1   1    1   1    1   1     J-      1.0    1.0      'NO'        /
/
```

Here one Carter-Tracy aquifer is connected to a single cell (1, 1, 1) at the J- face (or X- face) of the cell.

6.3.9 AQUNNC – DEFINE NUMERICAL AQUIFER NON-NEIGHBOR CONNECTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The AQUNNC keyword defines Numerical Aquifer Non-Neighbor Connections.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.10 AQUNUM – DEFINE NUMERICAL AQUIFER PROPERTIES

Description

The AQUNUM keyword defines the properties of numerical aquifers, including which grid blocks in the model should be utilized as part of the numerical aquifer. Each row entry in the AQUNUM keyword defines one numerical aquifer. Note that a numerical aquifer may consists of more than one grid cell, in order to better describe the water influx from the aquifer to the grid.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	AQUID	AQUID is a positive integer greater than or equal to one and less than or equal to the maximum number of numerical aquifers as defined by the MXNAQN variable on the AQUDIMS keyword in the RUNSPEC section, that defines the aquifer to be connected to the grid.			None
2	I	A positive integer that defines the cell in the I-direction that represents the AQUID aquifer, and which must be greater than or equal to one and less than or equal to NX.			None
3	J	A positive integer that defines the cell in the J-direction that represents the AQUID aquifer, and which must be greater than or equal to one and less than or equal to NY.			None
4	K	A positive integer that defines the cell in the K-direction that represents the AQUID aquifer, and which must be greater than or equal to one and less than or equal to NZ.			None
5	AREA	AREA is a real positive value that defines the cross-sectional area of the aquifer used in calculating the aquifer connection transmissibility. The actual transmissibility between the numerical aquifer and the connected grid cell is the harmonic average of the aquifer connection transmissibility and the calculated connected cell transmissibility. The value entered for AREA does not effect the visualization of the cell in OPM ResInsight, as it is only used in calculating the transmissibility. Note that the AQUOPT1 variable on the AQUCON keyword in the GRID section allows one to use the value entered for AREA or to use the grid cell cross-sectional area instead for the transmissibility calculation.			
		ft^2	m^2	cm^2	None
6	LENGTH	LENGTH is a real positive value that defines the length of the numerical aquifer. Similar to the AREA variable, LENGTH is not constrained by the original host cell size and the value entered does not effect the visualization of the cell in OPM ResInsight.			
		feet	m	cm	None
7	PORO	PORO is a real positive number greater than zero and less than or equal to one that assigns the porosity to the numerical aquifer.			
		dimensionless	dimensionless	dimensionless	None

No.	Name	Description			Default
		Field	Metric	Laboratory	
8	PERM	PERM is a real positive number that assigns the permeability to the numerical aquifer.			
		mD	mD	mD	None
9	DATUM	DATUM is a real positive number that sets the reference datum depth of the numerical aquifer. Similar to the AREA variable, DEPTH is not constrained by the original host cell depth and the value entered does not effect the visualization of the cell in OPM ResInsight. If defaulted then the depth of cell (I, J, K) will be used			
		feet	m	cm	Cell Depth
10	PRESS	PRESS is a single positive value that defines the numerical aquifer pressure at DATUM. If PRESS is defaulted then the simulator will set the aquifer's initial reservoir pressure to be in equilibrium with the cells the aquifer is contacted to. This is the preferred manner to initialize the numerical aquifer.			
		psia	barsa	atma	1*
11	PVTNUM	PVTNUM is positive integer greater than zero and less than the NTPVT variable on the TABDIMS keyword in the RUNSPEC section, that defines the PVTW table allocated to the numerical aquifer. If defaulted then the PVT tables allocated to cell (I, J, K) will be used.			Cell PVTNUM
12	SATNUM	SATNUM is positive integer greater than zero and less than the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section, that defines the saturation tables allocated to the numerical aquifer. If defaulted then the saturation tables allocated to cell (I, J, K) will be used.			Cell SATNUM

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) The keyword is followed by up to MXNAQN records as defined on the AQUDIMS keyword in the RUNSPEC section
3) Each record is terminated by a "/" and the keyword should be terminated by a "/".

Table 6.10:AQUNUM Keyword Description

Numerical aquifers ares modeled as one-dimensional, with aquifer flow assumed to be in the direction defined by LENGTH, and flux out of the aquifer is through the cross sectional area defined by AREA. Note that, all the aquifer cells must be isolated from the reservoir cells, with only the AQUCON connections connecting to the actual reservoir cells.

The values entered on the AQUNUM keyword are used to calculate the aquifer's pore volume and the transmissibility between the aquifer and the connected cell faces defined on the AQUCON keyword. Thus:

1) The aquifer's pore volume is always calculated from the data entered on the AQUNUM keyword using $Pore\ \ Volume = AREA \times LENGTH \times PORO$ and any modifications to the host cell values performed in either the GRID or EDIT sections are always ignored for cells declared as numerical aquifers cells.

2) For the transmissibility calculation either the cross-sectional area (AREA) defined on the AQUNUM keyword may be used or the connecting cell cross-sectional area by setting the AQUOPT1 variable on the AQUCON keyword.

In order to full define a numerical aquifer one has to define the aquifer properties via the AQUNUM keyword, and how the aquifer is connected to the reservoir using the AQUCON keyword in the GRID or SOLUTION sections.

Note

If the AQUCON keyword has been utilized in the run deck then OPM Flow will write the AQUIFERN array to the *.INIT file in order to visualize the aquifer connections in OPM ResInsight.

This is accomplished by setting the AQUIFERN value to 2(AQUID-1) for cells connected to aquifer AQUID. If a cell is connected to multiple numerical aquifers then AQUIFERN is summed for all aquifers connected to a cell. Note that connecting cells to multiple aquifers is best avoided.

Finally for cells representing the numerical aquifers themselves, AQUIFERN is set to minus AQUID.

Using one aquifer cell should generally be sufficient, provided the aquifer properties are constant. However, employing multiple cells may be appropriate if the aquifer properties vary with distance or depth, which is not uncommon. Secondly, having multiple cells may help to minimize throughput-related convergence problems by increasing the pore volumes exponentially away from the reservoir cells. Typically, three to five aquifer cells are employed under theses circumstances.

The aquifer pore volume can be used to define the amount of pressure support; whereas, the aquifer transmissibility will influence the responsiveness of the aquifer.

See also the AQUDIMS keyword in the RUNSPEC section that defines the numerical aquifer dimensions.

Example

Given the following grid and aquifer dimensions in the RUNSPEC section:

```
--
--        MAX      MAX      MAX
--        NDIVIX   NDIVIY   NDIVIZ
DIMENS
          96       58       28                                                  /

--        AQF      AQF      AQF      AQF      AQF      AQF      AQF      AQF
--        MXAQN    MXNAQC   NIFTBL   NRIFTB   NANAQU   NCAMAX   MXNALI   MXAAQL
AQUDIMS
          3        3        1*        1*       1*       1*       1*       1*              /
```

The following numerical aquifer definition:

```
--
--        NUMERICAL AQUIFER DESCRIPTION
--
--        ID      - LOCATION - AQF       AQF      AQF    AQF   AQF     AQF   PVT SATNUM
--        NUMBER   I1   J1   K1   AREA      LENGTH   PORO   PERM DEPTH   PRES  TAB TAB
--
AQUNUM
          1         1    3   28   5.20E03   2.0E3    0.05   0.3  1*      1*    1*  1*    /
          1         1    2   28   5.20E06   2.0E6    0.05   0.3  1*      1*    1*  1*    /
          1         1    1   28   5.20E09   2.0E9    0.05   0.3  1*      1*    1*  1*    /
/
```

defines one numerical aquifer consisting of three cells. The connection to the grid cells would take the form of:

```
--
--        NUMERICAL AQUIFER CONNECTIONS
--
--       ID     ---------- BOX ---------   CONNECT  TRANS  TRANS  ADJOIN
--       NUMBER I1  I2   J1  J2   K1  K2   FACE     MULT   OPTN   CELLS
AQUCON
         1       1   1    4  58   28   28  'K+'     1.3    1*     1*          /
         1       2  96    1  58   28   28  'K+'     1.3    1*     1*          /
/
```

that creates a basal aquifer[119].

[119] *Basal Aquifer: An aquifer located at the bottom of a geologic unit.*

6.3.11 AUTOCOAR - DEFINE AUTO REFINEMENT GRID COARSEN AREA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The AUTOCOAR keyword defines an area in the global grid that should be coarsen for when the AUTOREF keyword has been declared in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.12 BCCON – DEFINE BOUNDARY CONDITIONS CONNECTIONS

Description

The BCCON keyword defines the grid connections for the boundary conditions.

Together the BCCON and BCPROP keywords define the boundary conditions for the model, and can be used to set boundary conditions for when external influx or efflux volumes are influencing the reservoir pressure and production history. For example, when the average reservoir pressure remains constant throughout the production period due to water influx, or gas migration from an external source.

Note

This is an OPM Flow specific keyword and will therefore cause an error in the commercial simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	INDEX	A positive integer that identifies the boundary condition.			None
2	I1	A positive integer that defines the lower bound of the grid in the I-direction for which the boundary conditions are to be applied, must be greater than or equal 1 and less than or equal to I2 and NX.			1
2	I2	A positive integer that defines the upper bound of the grid in the I-direction for which the boundary conditions are to be applied, must be greater than or equal to I1 and less than or equal to NX			NX
3	J1	A positive integer that defines the lower bound of the grid in the J-direction for which the boundary conditions are to be applied, must be greater than or equal 1 and less than or equal to J2 and NY.			1
4	J2	A positive integer that defines the upper bound of the grid in the J-direction for which the boundary conditions are to be applied, must be greater than or equal to J1 and less than or equal to NY.			NY
5	K1	A positive integer that defines the lower bound of the grid in the K-direction for which the boundary conditions are to be applied, must be greater than or equal to one and less than or equal to K2 and NZ.			1
6	K2	A positive integer that defines the upper bound of the grid in the K-direction for which the boundary conditions are to be applied, must be greater than or equal to K1 and less than or equal to NZ.			NZ
7	DIRECT	A character string that defines the direction to apply the boundary conditions, and should be set to one of the following X, Y, or Z for the positive direction, or X-, Y- or Z- for the negative direction.			None

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.

2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.11: BCCON Keyword Description

See also the AQUFLUX keyword that is supported by OPM Flow in both the SOLUTION and SCHEDULE sections, to define a constant flux analytical aquifer.

If the BCCON and BCPROP keywords are not present in the input deck, then the boundary conditions for the model are set to be no flow, which is the normal behavior in both OPM Flow and the commercial simulator.

The BC keyword has been replaced by the BCCON and BCPROP keywords.

Examples

The first example shows how to set a constant pressure boundary using TYPE equal to FREE:

```
--
--       DEFINE BOUNDARY CONDITIONS CONNECTION (OPM FLOW SOLUTION GRID KEYWORD)
--
--INDEX  ---------- BOX ---------   BC
--       I1  I2   J1  J2   K1  K2   DIRC
BCCON
1        1   1    1   1*   1   1*   X-    /
2        1   1*   1   1    1   1*   Y     /
/

--
--       DEFINE BOUNDARY CONDITIONS PROPERTIES (OPM FLOW SOLUTION GRID KEYWORD)
--
--INDEX  BC         BC     BC     BC     BC
--       TYPE       PHASE  RATE   PRESS  TEMP
BCPROP
1        FREE       1*     1*     1*     1*    /
2        FREE                                 /
/
```

With this option it is only necessary to define the boundary cells and all the other parameters (PHASE, RATE, PRESS, and TEMP) can be defaulted, as they are ignored when TYPE equals FREE.

The next example is based on NX, NY and NZ equal to 20, 1, 10 respectively, on the DIMENS keyword in the RUNSPEC section, and shows how different boundary types can be assigned to different parts of the model.

```
--
--       DEFINE BOUNDARY CONDITIONS CONNECTION (OPM FLOW SOLUTION GRID KEYWORD)
--
--INDEX  ---------- BOX ---------   BC
--       I1  I2   J1  J2   K1  K2   DIRC
BCCON
1        1   1    1   1    1   10   X-    /
2        20  20   1   1    1   10   X     /
/

--
--       DEFINE BOUNDARY CONDITIONS PROPERTIES (OPM FLOW SOLUTION GRID KEYWORD)
--
--INDEX  BC         BC     BC     BC     BC
--       TYPE       PHASE  RATE   PRESS  TEMP
BCPROP
1        RATE       GAS    1*     256.0  100.0 /
2        FREE       4*                         /
/
```

The last example shows how the DIRICHLET boundary condition option may be used:

```
--
--       DEFINE BOUNDARY CONDITIONS CONNECTION (OPM FLOW SOLUTION GRID KEYWORD)
--
--INDEX  ---------- BOX ---------   BC
--       I1  I2   J1  J2   K1  K2   DIRC
BCCON
1        1   1    1   1*   1   1*   X-    /
2        1   1*   1   1    1   1*   Y     /
/

--
--       DEFINE BOUNDARY CONDITIONS PROPERTIES (OPM FLOW SOLUTION GRID KEYWORD)
--
--INDEX  BC         BC     BC    BC     BC
--       TYPE       PHASE  RATE  PRESS  TEMP
BCPROP
1        DIRICHLET  WAT    1*    256.0  100.0 /
2        DIRICHLET  WAT    1*    1*     100.0 /
/
```

Here, the first line sets both the pressure and temperature at the boundary, and the second line defaults the pressure entry, so that the simulator calculated initial boundary pressure will be used.

6.3.13 BOUNDARY – DEFINE A BOUNDARY BOX FOR PRINTING

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The BOUNDARY keyword defines a rectangular grid for printing various arrays to the output print file (*.PRT); thus, avoiding printing all the elements in the selected array.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.14 BOX - DEFINE A RANGE OF GRID BLOCKS TO ENTER PROPERTY DATA

Description

BOX defines a range of grid blocks for which subsequent data is assigned for all the cells in the defined BOX. Values are set for cells within the defined box grid using natural reading order, initially along the I-direction then J-direction and finally the K-direction. If fewer values are assigned than exist within the defined block space, then subsequent values are set starting from the next block that was not previously assigned for that property. This is the same behavior as applies to setting grid properties for an unboxed grid.

Note that the BOX grid is reset by the keyword ENDBOX by resetting the current defined BOX to be the whole grid. The keyword can be used for any array and for all grid types.

No.	Name	Description	Default
1	I1	A positive integer that defines the lower bound of the array in the I-direction to be modified must be greater than or equal 1 and less than or equal to I2 and NX.	1
2	I2	A positive integer that defines the upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
3	J1	A positive integer that defines the lower bound of the array in the J-direction to be modified must be greater than or equal 1 and less than or equal to J2 and NY.	1
4	J2	A positive integer that defines the upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
5	K1	A positive integer that defines the lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
6	K2	A positive integer that defines the upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) The keyword is terminated by a "/".

Table 6.12: BOX Keyword Description

See also the ADD, COPY, ENDBOX, EQUALS, and MULTIPLY keywords can also be used to enter data in a subset of the model.

Examples

```
--
--        DEFINE A BOX GRID FOR THE BOTTOM LAYER OF A 100 X 100 X 20 MODEL
--
--        ---------- BOX ---------
--        I1  I2   J1  J2   K1  K2
BOX
          1*  1*   1*  1*   20  20 / SELECT THE BOTTOM LAYER
--
--        DEFINE THE POROSITY AND OTHER PROPERTIES ON THE BOX GRID
--
PORO
          10000*0.300
/
PERMX
          5000*100.0   5000*75.0
/
NTG
          10000*0.500
/
--
--        RESET THE INPUT BOX TO BE THE FULL MODEL
--
ENDBOX
```

The above example set the BOX grid to be the last layer in the model which means that 100 x 100, that is 10,000 values need to entered for each property.

Alternatively, one could use the EQUALS keyword to accomplish the same thing.

```
-- -- ARRAY    CONSTANT --  ---------- BOX ---------
--                         I1  I2   J1  J2   K1  K2
EQUALS
   'PORO'      0.3000       1*  1*   1*  1*   20  20 / PORO  TO 0.30 IN LAYER 20
   'PERMX'     100.00       1*  1*   1   50   20  20 / PERMX TO 100. IN LAYER 20
   'PERMX'      75.00       1*  1*   51  100  20  20 / PERMX TO 75.0 IN LAYER 20
   'NTG'       0.5000       1*  1*   1*  1*   20  20 / NTG   TO 0.50 IN LAYER 20
/
```

Note

It is good practice to always use the ENDBOX keyword to reset the input back to the full grid when all the modifications for a sub-grid have been completed.

6.3.15 BTOBALFA – DUAL POROSITY MATRIX TO FRACTURE MULTIPLIER (ALL CELLS)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The BTOBALFA keyword defines a dual porosity matrix to fracture multiplier that is applied to all cells, for when the Dual Porosity model has been activated by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section.

See also the BTOBALFV keyword in the GRID section that applies a multipliers to individual cells.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.16 BTOBALFV – DUAL POROSITY MATRIX TO FRACTURE MULTIPLIER (INDIVIDUAL CELLS)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The BTOBALFV keyword defines a dual porosity matrix to fracture multiplier that is applied to individual cells, for when the Dual Porosity model has been invoked by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section.

See also the BTOBALFAV keyword in the GRID section that applies a constant multiplier to all cells.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.17 CARFIN – DEFINE A CARTESIAN LOCAL GRID REFINEMENT

Description

CARFIN defines a Cartesian Local Grid Refinement ("LGR") in a cell or a group of cells in the host grid, for when LGRs have been activated for the input deck using the LGR keyword in the RUNSPEC section. The keyword marks the start of an LGR description section and all subsequent keywords between the CARFIN and ENDFIN keywords are deemed to be associated with the current LGR and not the host grid.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	LGRNAME	A character string of up to eight characters in length that defines the LGR name for which the LGR is being being defined.	None
2	I1	A positive integer that defines the lower index of the global or host grid in the I-direction to be refined; must be greater than or equal 1 and less than or equal to I2 and NX on the DIMENS keyword in the RUNSPEC section.	None
3	I2	A positive integer that defines the upper index of the global or host grid in the I-direction to be refined; must be greater than or equal I and II, and less than or equal to NX on the DIMENS keyword in the RUNSPEC section.	None
4	J1	A positive integer that defines the lower index of the global or host grid in the J-direction to be refined; must be greater than or equal 1 and less than or equal to J2 and NY on the DIMENS keyword in the RUNSPEC section.	None
5	J2	A positive integer that defines the upper index of the global or host grid in the J-direction to be refined; must be greater than or equal 1 and JI, and less than or equal to NY on the DIMENS keyword in the RUNSPEC section.	None
6	K1	A positive integer that defines the lower index of the global or host grid in the K-direction to be refined; must be greater than or equal 1 and less than or equal to K2 and NZ on the DIMENS keyword in the RUNSPEC section.	None
7	K2	A positive integer that defines the upper index of the global or host grid in the K-direction to be refined; must be greater than or equal 1 and KI, and less than or equal to NZ on the DIMENS keyword in the RUNSPEC section.	None
8	NX	A positive integer value that defines the number of LGR grid blocks in the x direction for Cartesian grids or the number of grid blocks in the r direction for radial grids	None
9	NY	A positive integer value that defines the number of LGR grid blocks in the y direction for Cartesian grids or the number of grid blocks in the theta direction for radial grids.	None
10	NZ	A positive integer value that defines the number of LGR grid blocks in the z direction for both Cartesian and radial grids.	None
11	MXWELS	A positive integer defining the maximum number of wells contained in this LGR.	None

No.	Name	Description	Default
12	HOSTNAME	A character string of up to eight characters in length that defines the host grid name for nested refinements. The default value of "GLOBAL" sets the host name to the global grid, that is for a conventional LGR. A nested refinement is when the HOSTNAME is a previously declared LGR for which the current LGR is specifying a further LGR refinement.	GLOBAL
Notes: 1) The keyword is terminated by a "/".			

Table 6.13: CARFIN Keyword Description

Note that if the Dual Porosity option has be activated by either the DUALPORO or DUALPERM keywords in the RUNSPEC section, then the host grid definition (I1-I2, J1-J2, K1-K2) applies only to the matrix cells; however, the LGR NZ parameter in this case must include the fracture blocks, similar to the NZ parameter on the DIMENS keyword. This means that all property data should be entered for both the matrix and fracture cells in the LGR description.

Example

The example below defines an LGR in the global grid, named LGR-OP01 with a maximum of one well allowed in the LGR.

```
--
--        CARFIN LGR GRID COMMANDS
--
--        LGR         ----- HOST GRID ------    -- CARFIN GRID --   MAX      HOST
--        NAME        I1   I2   J1   J2   K1   K2      NX     NY     NZ    WELLS    NAME
CARFIN
          LGR-OP01    24   24   87   87    1   50       3      3     50      1      GLOBAL /

ENDFIN
```

Here the one global cell in the areal plane (24, 87) is divided into three LGR cells in the x-direction and three cells in the y-direction. Since no other property data is given, then the LGR cells take their properties from the host grid, that is the global grid.

6.3.18 COALNUM – DEFINE THE COAL REGION NUMBERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The COALNUM keyword defines the coal region numbers for each grid block used with the Coal Bed Methane option ("CBM"). OPM Flow does not have a CBM option; however, the keyword is documented here for completeness.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	COALNUM	COALNUM defines an array of positive integers assigning a grid cell to a particular coal region. The maximum number of COALNUM regions is set by the NTCREG variable on REGDIMS keywords in the RUNSPEC section.	1

Notes:

1) A total of NX x NY x NZ integer values, as defined by the DIMENS keyword in the RUNSPEC section, must be specified for the array.
2) If a cell is not assigned a COALNUM region then the default value of 1 will be used.
3) COALNUM value of 0 sets the cell be a non-coal region.
4) The keyword is terminated by a "/".

Table 6.14: COALNUM Keyword Description

Example

The example below sets three COALNUM regions for a 4 x 5 x 2 model.

```
--
--       DEFINE COALNUM REGIONS FOR ALL CELLS
--
COALNUM
         2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
         3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

The above will no effect in an OPM Flow input deck.

6.3.19 COARSEN – DEFINE GRID COARSENING CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The COARSEN keyword defines how a set of cells should be coarsened for when the Local Grid Refinement ("LGR") option has been activated by LGR keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.20 COLLAPSE – DEFINE COMPRESSED VERTICAL EQUILIBRIUM CELLS

Description

The COLLAPSE keyword defines the which cells can be collapsed in a collapsed Vertical Equilibrium ("VE") run when the VE option has been invoked via the VE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.21 COLUMNS – DEFINE INPUT FILE COLUMN MARGINS

The COLUMNS keyword defines the input file column margins; characters outside the margins are ignored by the input parser.

See *COLUMNS – Define Input File Column Margins* in the GLOBAL section for a full description.

6.3.22 COORD – DEFINE A SET OF COORDINATES LINES FOR A RESERVOIR GRID

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

COORD defines a set of coordinate lines or pillars for a reservoir grid via an array. A total of 6 x (NX+1) x (NY+1) values must be specified for each coordinate data set (or reservoir). For multiple reservoirs, where NUMRES is greater than one, there must be 6 x (NX+1) x (NY+1) x NUMRES values. In OPM Flow NUMRES can only be set to one.

For Cartesian geometry, each line is defined by the (x, y, z) coordinates of two distinct points on the line. The lines are entered with I cycling fastest then J. For radial geometry, each line is defined by the (r, theta, z) coordinates of two distinct points on the line. The lines are entered with R cycling fastest then THETA.

The keyword can only be used with Irregular Corner-Point Grids.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	X1-Column	Top X coordinate			
2	Y1-Column	Top Y coordinate			
3	Z1-Column	Top Z coordinate			
4	X2-Column	Base X coordinate			
5	Y2-Column	Base Y coordinate			
6	Z2-Column	Base Z coordinate			
		feet	metres	cm	None

Notes:

1) THETA values are in degrees for all units.
2) Regular Cartesian and Radial grid keywords cannot be used with this keyword, that is: DR, DRV, DTHETA, DTHETAV, DX, DXV, DY, DYV, DZ, INRAD, and TOPS.
3) The keyword is terminated by a "/".

Table 6.15: COORD Keyword Description

See also the SPECGRID, COORDSYS and ZCORN keywords to fully define an Irregular Corner-Point Grid.

Example

```
--
--       SPECIFY VERTICAL COORDINATE LINES FOR A REGULAR 3 x 2 GRID
--       (DX = 100 and DY = 200)
--
--       X1     Y1    Z1      X2     Y2    Z2
--       ---    ---   ----    ---    ---   ----
COORD
           0      0   1000      0      0   5000
         100      0   1000    100      0   5000
         200      0   1000    200      0   5000
         300      0   1000    300      0   5000
           0    200   1000      0    200   5000
         100    200   1000    100    200   5000
         200    200   1000    200    200   5000
         300    200   1000    300    200   5000
           0    400   1000      0    400   5000
         100    400   1000    100    400   5000
         200    400   1000    200    400   5000
         300    400   1000    300    400   5000
/
```

The above example defines vertical coordinate lines for a regular 3 by 2 grid with DX equal to 100 and DY equal to 200.

6.3.23 COORDSYS – DEFINE COORDINATE GRID OPTIONS

Description

This keyword sets various options for when multiple grid systems are being used, as declared by the NUMRES keyword in the RUNSPEC section. OPM Flow does not support multiple grid systems. The keyword is also used to stipulate for radial grids if the completion of the circle in the THETA direction should be implemented using non-neighbor connections.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description	Default
1	K1	A positive integer that defines the lower bound of the array in the K-direction for the given grid system.	None
2	K2	A positive integer that defines the upper bound of the array in the K-direction for the given grid system.	None
3	COMPLETE	COMPLETE is a defined character string that determines for radial grids if the circle should be completed in THETA direction, and should be set to COMP to complete the circle, or INCOMP for not completing the circle.	INCOMP
4	CONNECT	A defined character string that declares how the reservoir below should be connected to the given reservoir, and should be set to JOIN to connect the two reservoirs by calculating the inter-reservoir transmissibilities, or SEPARATE to isolate the reservoirs.	SEPARATE
5	R1	R1 is a positive integer defining the lower reservoir unit that is is connected to the given reservoir unit.	Current Reservoir Record
6	R2	R2 is a positive integer defining the upper reservoir unit that is is connected to the given reservoir unit.	

Notes:

1) The DIMENS keyword defines the dimensions of the model (NX, NY and NZ) and the NUMRES keyword the number of multiple grid systems (reservoirs), both keywords are in the RUNSPEC section.
2) Each record must be terminated by a "/" and there must be exactly NUMRES records entered for the keyword.
3) There is no "/" terminator for this keyword.

Table 6.16: COORDSYS Keyword Description

Example

```
--
--       DEFINE COORDINATE GRID OPTIONS
--
--       K1     K2     COMP    CONNECT  LOWER  UPPER
--       Layer  Layer  CIRCLE  RES      RES    RES
COORDSYS
         1      1      COMP                            /
/
```

The above example connects the circle in the THETA direction for the RADIAL model, for when the number of grids have been set to one via the NUMRES keyword in the SCHEDULE section.

6.3.24 COPY – COPY ARRAY DATA TO ANOTHER ARRAY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The COPY keyword copies an array (or part of an array) to another array or part of an array. The arrays can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the COPY keyword is being used.

No.	Name	Description	Default
1	ARRAY-1	The name of the array to be copied from. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	ARRAY-2	The name of the array to be copied to. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
3	I1	A positive integer that defines the lower bound of the array in the I-direction to be modified must be greater than or equal 1 and less than or equal to I2 and NX.	1
4	I2	A positive integer that defines the upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
5	J1	A positive integer that defines the lower bound of the array in the J-direction to be modified must be greater than or equal 1 and less than or equal to J2 and NY.	1
6	J2	A positive integer that defines the upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
7	K1	A positive integer that defines the lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
8	K2	A positive integer that defines the upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.17: COPY Keyword Description

The applicable arrays for each section are defined in Table 6.18 on the following page.

COPY Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL	ENDNUM	PRESSURE		
DY	PORV	SWCR	EQLNUM	SWAT		
DZ	TRANX	SWU	FIPNUM	SGAS		
PERMX	TRANY	SGL	IMBNUM	RV		
PERMY	TRANZ	SGCR	MISCNUM	RS		
PERMZ	DIFFX	SGU	PVTNUM	TBLK		
MULTX	DIFFY	KRW	ROCKNUM	GI		
MULTY	DIFFZ	KRO	SATNUM	OILAPI		
MULTZ	TRANR	KRG	WH2NUM	SALT		
DR	TRANTHT	PCG		GASCONC		
THETA	DIFFR	PCW		SOLVCONC		
PERMR	DIFFTHT			SOLVFRAC		
PERMTHT				SFOAM		
DZNET				SPOLY		
PORO						
NTG						
FLUXNUM

DIFFTHT						

Table 6.18: COPY Keyword Applicable Arrays by Section

Example

```
--
--        SOURCE       DESTIN.       ---------- BOX ---------
--                                    I1  I2   J1  J2   K1  K2
COPY
          PERMX        PERMY         1*  1*   1*  1*   1*  1* / CREATE PERMY
          PERMX        PERMZ         1*  1*   1*  1*   1*  1* / CREATE PERMZ
/

--
--        ARRAY        CONSTANT      ---------- BOX ---------
--                                    I1  I2   J1  J2   K1  K2
MULTIPLY
          PERMZ        0.50000       1*  1*   1*  1*   1*  1* / PERMZ * 0.5
/
```

The above example copies PERMX array to the PERMY and PERMZ arrays in the GRID section for all grid blocks in the model. The PERMZ array is then multiplied by 0.5 for all grid blocks in the model.

6.3.25 COPYBOX – COPY ARRAY DATA DEFINED BY A BOX

Description

The COPYBOX keyword copies an array (or part of an array) to another part of the same array. The array can be real or integer depending on the array type; however, the array that can be operated on is dependent on which section the COPYBOX keyword is being used.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	ARRAY-1	The name of the array to be copied This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	I1	A positive integer that defines the SOURCE lower bound of the array in the I-direction to be modified must be greater than or equal 1 and less than or equal to I2 and NX.	1
3	I2	A positive integer that defines the SOURCE upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
4	J1	A positive integer that defines the SOURCE lower bound of the array in the J-direction to be modified must be greater than or equal 1 and less than or equal to J2 and NY.	1
5	J2	A positive integer that defines the SOURCE upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
6	K1	A positive integer that defines the SOURCE lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
7	K2	A positive integer that defines the SOURCE upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ
8	I3	A positive integer that defines the DESTINATION lower bound of the array in the I-direction to be modified must be greater than or equal 1 and less than or equal to I2 and NX.	1
9	I4	A positive integer that defines the DESTINATION upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
10	J3	A positive integer that defines the DESTINATION lower bound of the array in the J-direction to be modified must be greater than or equal 1 and less than or equal to J2 and NY.	1
11	J4	A positive integer that defines the DESTINATION upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY

No.	Name	Description	Default
12	K3	A positive integer that defines the DESTINATION lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
13	K4	A positive integer that defines the DESTINATION upper bound of the array in the K-direction to be modified must be greater than or equal to KI and less than or equal to NZ.	NZ

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.

2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.19: COPYBOX Keyword Description

Note that the SOURCE and DESTINATION arrays must be of the same size in all dimensions and the applicable arrays for each section are defined in Table 6.20.

COPYBOX Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX		SWL	ENDNUM			
DY		SWCR	EQLNUM			
DZ		SWU	FIPNUM			
PERMX		SGL	IMBNUM			
PERMY		SGCR	MISCNUM			
PERMZ		SGU	PVTNUM

DIFFTHT						

Table 6.20: COPYBOX Keyword Applicable Arrays by Section

Example

```
--
--        SOURCE    ------ SOURCE BOX ------    ---- DESTINATION BOX ----
--        ARRAY     I1  I2   J1  J2   K1  K2    I1  I2   J1  J2   K1  K2
COPYBOX
           PORO     1*  1*   1*  1*   12  14    1*  1*   1*  1*   15  17 / PORO
           PERMX    1*  1*   1*  1*   12  14    1*  1*   1*  1*   15  17 / PERMX
/
```

The above example copies all the PORO and PERMX values in layers 12 to 14 to layers 15 and 17.

6.3.26 COPYREG – COPY AN ARRAY TO ANOTHER ARRAY BASED ON A REGION NUMBER

Description

The COPYREG keyword copies a specified array or part of an array based on cells with a specific region number to another array. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the COPYREG keyword is read by the simulator. The property arrays can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the COPYREG keyword is being used.

No.	Name	Description	Default
1	ARRAY-1	The name of the array to be copied from. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	ARRAY-2	The name of the array to be copied to. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
3	REGION NUMBER	Integer REGION NUMBER is the region for which the array data in (1) should be copied to array data in (2).	None
4	REGION ARRAY	The REGION ARRAY to use for selecting the REGION NUMBER in (3) for selecting the data to be copied. REGION ARRAY can have the following values: 1) F for the FLUXNUM array 2) M for the MULTNUM array 3) O for the OPERNUM array	M
Notes: 1) Where the REGION NUMBER should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section. 2) Each record must be terminated by a "/" and the keyword is terminated by a "/".			

Table 6.21: COPYREG Keyword Description

The applicable arrays for each section are defined in Table 6.22.

COPYREG Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL	ENDNUM	PRESSURE		
DY	PORV	SWCR	EQLNUM	SWAT		
DZ	TRANX	SWU	FIPNUM	SGAS		
PERMX	TRANY	SGL	IMBNUM	RV		
PERMY	TRANZ	SGCR	MISCNUM	RS		
PERMZ	DIFFX	SGU	PVTNUM	TBLK		

COPYREG Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
MULTX	DIFFY	KRW	ROCKNUM	GI		
MULTY	DIFFZ	KRO	SATNUM	OILAPI		
MULTZ	TRANR	KRG	WH2NUM	SALT		
DR	TRANTHT	PCG		GASCONC		
THETA	DIFFR	PCW		SOLVCONC		
PERMR	DIFFTHT			SOLVFRAC		
PERMTHT				SFOAM		
DZNET				SPOLY		
PORO						
NTG						
FLUXNUM						
MULTNUM						
MPANUM						
DIFFX						
DIFFY						
DIFFZ						
DIFFR						
DIFFTHT						

Table 6.22: COPYREG Keyword Applicable Arrays by Section

Example

```
--
--        COPY AN ARRAY TO ANOTHER ARRAY BASED ON A REGION NUMBER
--
--        ARRAY     ARRAY     REGION   REGION ARRAY
--        FROM      TO        NUMBER    M / F / O
COPYREG
          PERMX     PERMY     1         M                  / COPY PERMX TO PERMY
          PERMX     PERMZ     1         M                  / COPY PERMX TO PERMZ
/
--
--        NOW RESET PERMZ BASED ON THE MULTNUM REGION NUMBER
--
--
--        MULTIPLY AN ARRAY BY A CONSTANT BASED ON A REGION NUMBER
--
--        ARRAY     CONSTANT  REGION   REGION ARRAY
--                  VALUE     NUMBER    M / F / O
MULTIREG
          PERMX     0.95      1         M                  /
/
```

The above example first copies the PERMX property array for region number one to the PERMY and PERMZ property arrays for region one using the MULTNUM array to define the region numbers. After which PERMZ property array for region one is multiplied by 0.5 using the MULTIREG keyword.

6.3.27 CRITPERM – DEFINE MINIMUM PERMEABILITY FOR VERTICAL EQUILIBRIUM GRID CELL COMPRESSION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The CRITPERM keyword is used to define the minimum permeability for Vertical Equilibrium("VE") grid cell compression, for when the Vertical Equilibrium formulation has been activated by the VE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.28 DEBUG – DEFINE THE DEBUG DATA TO BE PRINTED TO FILE

This keyword defines the debug data to be written to the debug file (*.DBG). This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

See *DEBUG – Define the Debug Data to be Printed to File* in the GLOBAL section for a full description.

6.3.29 DIFFMR – DEFINE GRID BLOCK RADIAL DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMR keyword defines the radial direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.30 DIFFMR- – DEFINE GRID BLOCK NEGATIVE RADIAL DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMR- keyword defines the negative radial direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.31 DIFFMTH- – DEFINE GRID BLOCK NEGATIVE THETA DIRECTION DIFFUSIVITY MULTIPLIERS

Description

The DIFFMR- keyword defines the negative theta direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.32 DIFFMTHT – DEFINE GRID BLOCK THETA DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMTHT keyword defines the theta direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.33 DIFFMX – DEFINE GRID BLOCK X-DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMX keyword defines the x-direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.34 DIFFMX- – DEFINE GRID BLOCK NEGATIVE X-DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMX- keyword defines the negative x-direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.35 DIFFMY – DEFINE GRID BLOCK Y-DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMY keyword defines the y-direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.36 DIFFMY- – DEFINE GRID BLOCK NEGATIVE Y-DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMY- keyword defines the negative y-direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.37 DIFFMZ – DEFINE GRID BLOCK Z-DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMZ keyword defines the z-direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.38 DIFFMZ- – DEFINE GRID BLOCK NEGATIVE Z-DIRECTION DIFFUSIVITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFMZ- keyword defines the negative z-direction diffusivity multipliers for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.39 DOMAINS – DEFINE THE PARALLEL DOMAIN PROPERTIES

Description

The DOMAINS keyword defines the parallel domain properties for when parallel processing has been invoked by the PARALLEL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to run OPM Flow in parallel mode.

6.3.40 DPGRID – ACTIVATE THE MATRIX CELL TO FRACTURE CELL OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DPGRID keyword activates the matrix cell to fracture cell option for dual porosity runs for when a Dual Porosity model has been activated by either the DUALPORO or DUALPERM keywords in the RUNSPEC section. The keyword allows for only the matrix grid data to be entered and the missing fracture cells are set to the inputted matrix cells.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.41 DPNUM – DEFINE DUAL AND SINGLE POROSITY GRID BLOCK ARRAY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

In dual porosity runs only, that is not dual permeability runs, the DPNUM keyword defines which wells should be treated as single porosity cells and which cells should be treated as dual porosity cells, for when the Dual Porosity model has been activated by the DUALPORO keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.42 DR - DEFINE THE SIZE OF GRID BLOCKS IN THE R DIRECTION FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

DR defines the size of all grid blocks in the R direction via an array for each cell in the model. The RADIAL or SPIDER keyword in the RUNSPEC section should be activated to indicate that radial or spider geometry is being used.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DR	DR is an array of real numbers describing the cell size in the R direction for each cell in the model in a radial grid. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The first layer (K=1) must always be fully defined; however, subsequent layers may be default and if defaulted they will take the values from the layer above.
3) The keyword is terminated by a "/".

Table 6.23: DR Keyword Description

Note that the SPIDER keyword activates OPM Flow's radial grid geometry option for the model. This keyword will create a spiderweb-shaped grid based on a corner-point grid using the standard radial grid keywords: INRAD, DRV, DTHETAV, DZ/DZV etc. in the GRID the section. A spider grid can be viewed in 3D in OPM ResInsight unlike radial grids that cannot be viewed in the software. To overcome this, the simulator now converts radial grids to Irregular Corner-Point Grids and adjusts the model's pore volume to reflect radial coordinates; thus, overcoming the display limitation.

See also the DRV, DTHETAV, DZ and TOPS keywords in the GRID section to fully define a radial or spider grid model.

Example

Given the dimensions of the grid in the RUNSPEC section to be 10,1, 8 for NX, NY and NZ respectively, we first define the inner radius of the radial model,

```
--
--       INNER RADIUS OF FIRST GRID BLOCK IN THE RADIAL DIRECTION
--
INRAD
         0.25
/
```

and then DR should be defined as:

```
--
--       DEFINE GRID BLOCK R DIRECTION CELL SIZE
--
DR
          1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.0
         1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.0
          1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.0
          1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.0
          1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.0
          1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.0
          1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.0
    /
```

The above example defines the size of the cells in the R direction based on 80 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

Note that since the first layer (K=1) must be defined and subsequent layers default to the layer above then:

```
--
--       INNER RADIUS OF FIRST GRID BLOCK IN THE RADIAL DIRECTION
--
INRAD
         0.25
/
--
--       DEFINE GRID BLOCK R DIRECTION CELL SIZE
--
DR
          1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.0
    /
```

is equivalent to previous example.

6.3.43 DRV - DEFINE THE SIZE OF GRID BLOCKS IN THE R DIRECTION VIA A VECTOR

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

DRV defines the size of grid blocks in the R direction via a vector as opposed to defining the property for each cell for a Radial or Spider Grid. The RADIAL or SPIDER keyword in the RUNSPEC section should be activated to indicate that radial or spider geometry is being used.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DRV	DRV is a vector of real numbers describing the cell size for the grid blocks in the R direction in a radial grid. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	None
Notes: 1) The number of entries should correspond to the NX parameter on the DIMENS keyword in the RUNSPEC section 2) The keyword is terminated by a "/".					

Table 6.24: DRV Keyword Description

Note that the SPIDER keyword activates OPM Flow's radial grid geometry option for the model. This keyword will create a spiderweb-shaped grid based on a corner-point grid using the standard radial grid keywords: INRAD, DRV, DTHETAV, DZ/DZV etc. in the GRID the section. A spider grid can be viewed in 3D in OPM ResInsight unlike radial grids that cannot be viewed in the software. To overcome this, the simulator now converts radial grids to Irregular Corner-Point Grids and adjusts the model's pore volume to reflect radial coordinates; thus, overcoming the display limitation.

See also the DR, DTHETAV, DZ and TOPS keywords in the GRID section to fully define a radial or spider grid model.

Example

```
--
--        INNER RADIUS OF FIRST GRID BLOCK IN THE RADIAL DIRECTION
--
INRAD
          0.25
/
--
--        DEFINE GRID BLOCK SIZES IN THE R DIRECTION
--
DRV
          1.75  2.32  5.01  10.84  23.39  50.55  109.21  235.92  509.68  1101.08 /
```

The above example defines the size of the cells in the R direction based on NX equals 10 on the DIMENS keyword in the RUNSPEC section. Note the INRAD keyword to define the inner radius of the radial grid.

6.3.44 DTHETA - DEFINE THE SIZE OF GRID BLOCKS IN THE THETA DIRECTION FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

DTHETA defines the size of all grid blocks in the Theta direction via an array for each cell in model. The RADIAL or SPIDER keyword in the RUNSPEC section should be activated to indicate that radial or spider geometry is being used.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DTHETA	DTHETA is an array of real numbers describing the cell size in the THETA direction in radial grids for each cell in the model. Repeat counts may be used, for example 10*25.0			
		degrees	degrees	degrees	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.25: DTHETA Keyword Description

Note that the SPIDER keyword activates OPM Flow's radial grid geometry option for the model. This keyword will create a spiderweb-shaped grid based on a corner-point grid using the standard radial grid keywords: INRAD, DRV, DTHETAV, DZ/DZV etc. in the GRID the section. A spider grid can be viewed in 3D in OPM ResInsight unlike radial grids that cannot be viewed in the software. To overcome this, the simulator now converts radial grids to Irregular Corner-Point Grids and adjusts the model's pore volume to reflect radial coordinates; thus, overcoming the display limitation. See also the DRV, DTHETAV, DZ and TOPS keywords in the GRID section to fully define a radial or spider grid model.

Example

Given the dimensions of the grid in the RUNSPEC section to be 10, 6, 1 for NX, NY and NZ respectively, then DTHETA should be defined as:

```
--
--       DEFINE GRID BLOCK SIZES IN THE THETA DIRECTION
--
DTHETA
         10*60.0
         10*60.0
         10*60.0
         10*60.0
         10*60.0
         10*60.0
/
```

The above example defines the size of the cells in the R direction based on 60 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.45 DTHETAV - SETS THE SIZE OF GRID BLOCKS IN THETA DIRECTION VIA A VECTOR

Description

DTHETAV defines the size of grid blocks in the THETA direction via a vector as opposed to defining the property for each cell for a Radial Grid. The RADIAL or SPIDER keyword in the RUNSPEC should be activated to indicate that radial geometry is being used.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DTHETAV	DTHETAV is a vector of real numbers describing the cell size for the grid blocks in the THETA direction in a radial grid. Repeat counts may be used, for example 10*100.0.			
		degrees	degrees	degrees	None
Notes: 1) The number of entries should correspond to the NY parameter of the DIMENS keyword in the RUNSPEC section. 2) The keyword is terminated by a "/".					

Table 6.26: DTHETA Keyword Description

Note that the SPIDER keyword activates OPM Flow's radial grid geometry option for the model. This keyword will create a spiderweb-shaped grid based on a corner-point grid using the standard radial grid keywords: INRAD, DRV, DTHETAV, DZ/DZV etc. in the GRID the section. A spider grid can be viewed in 3D in OPM ResInsight unlike radial grids that cannot be viewed in the software. To overcome this, the simulator now converts radial grids to Irregular Corner-Point Grids and adjusts the model's pore volume to reflect radial coordinates; thus, overcoming the display limitation.

See also the DRV, DZV and TOPS keywords to fully define a radial or spider grid model.

Example

```
--
--       DEFINE GRID BLOCK SIZES IN THE THETA DIRECTION (BASED ON NY = 6)
--
DTHETAV
         60.0  60.0  60.0  60.0  60.0  60.0                                  /
```

The above example defines the size of the cells in the THETA direction based on NY equals six in the DIMENS keyword in the RUNSPEC section.

6.3.46 DUMPFLUX – ACTIVATE WRITING OUT OF A FLUX FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates the writing out of a full field (the full grid) FLUX file for later processing in a Flux Boundary run. The Flux Boundary feature allows for the segmentation of the full grid into flux boundary areas which allow for a sub-area of the grid to be run and at the same time model the flux across the boundary derived from the main grid. The object of this feature is to be able to investigate the performance of various areas of the model without having to run the full field, thus improving computational efficiency and run times, but still obtain "reasonable" results due to the incorporation of the fluxes across the boundary.

This feature is not available in OPM Flow; however it is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE WRITING OUT OF A FLUX FILE
--
DUMPFLUX                                                                    /
```

The above example switches on the writing of the FLUX output file; the keyword has no effect and is ignored by the simulator.

6.3.47 DX - DEFINE THE SIZE OF GRID BLOCKS IN THE X DIRECTION FOR ALL CELLS

Description

DX defines the size of all grid blocks in the X direction via an array for each cell in a Cartesian Regular Grid model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DX	DX is an array of real numbers describing the cell size in the X direction for each cell in the model. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.27: DX Keyword Description

See also the DY, DZ and TOPS keywords to fully define a Cartesian Regular Grid.

Example

```
--
--       DEFINE GRID BLOCK X DIRECTION CELL SIZE (BASED ON NX x NY x NZ = 300)
--
DX
         300*1000                                                              /
```

The above example defines the size of the cells in the X direction based on 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.48 DXV - DEFINE THE SIZE OF GRID BLOCKS IN THE X DIRECTION VIA A VECTOR

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

DXV defines the size of grid blocks in the X direction via a vector as opposed to defining the X direction cell size for each cell for a Cartesian Regular Grid.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DXV	DXV is a vector of real numbers describing the cell size for the grid blocks in the X direction. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	None
Notes: 1) The number of entries should correspond to the NX parameter on the DIMENS keyword in the RUNSPEC section. 2) The keyword is terminated by a "/".					

Table 6.28: DXV Keyword Description

See also the DYV, DZV and TOPS keywords to fully define a Cartesian Regular Grid.

Example

```
--
--       DEFINE GRID BLOCK X DIRECTION CELL SIZE (BASED ON NX = 5)
--
DXV
         5*100                                                    /
```

The above example defines the size of the cells in the X direction based on NX equals 5 on the DIMENS keyword in the RUNSPEC section.

6.3.49 DY - DEFINE THE SIZE OF GRID BLOCKS IN THE Y DIRECTION FOR ALL CELLS

Description

DY defines the size of all grid blocks in the Y direction via an array for each cell in a Cartesian Regular Grid model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DY	DY is an array of real numbers describing the cell size in the Y direction for each cell in the model. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.29: DY Keyword Description

See also the DX, DZ and TOPS keywords to fully define a Cartesian Regular Grid.

Example

```
--
--        DEFINE GRID BLOCK Y DIRECTION CELL SIZE (BASED ON NX x NY x NZ = 300)
--
DY
          300*1000                                                              /
```

The above example defines the size of the cells in the Y direction based on 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.50 DYV - DEFINE THE SIZE OF GRID BLOCKS IN THE Y DIRECTION VIA A VECTOR

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

DYV defines the size of grid blocks in the Y direction via a vector as opposed to defining the Y direction cell size for each cell for a Cartesian Regular Grid.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DYV	DYV is a vector of real numbers describing the cell size for the grid blocks in the Y direction. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	None
Notes: 1) The number of entries should correspond to the NY parameter on the DIMENS keyword in the RUNSPEC section. 2) The keyword is terminated by a "/".					

Table 6.30: DYV Keyword Description

See also the DXV, DZV and TOPS keywords to fully define a Cartesian Regular Grid.

Example

```
--
--        DEFINE GRID BLOCK Y DIRECTION CELL SIZE (BASED ON NY = 5)
--
DYV
          5*100                                                              /
```

The above example defines the size of the cells in the Y direction based on NY equals 5 on the DIMENS keyword in the RUNSPEC section.

6.3.51 DZ - DEFINE THE SIZE OF GRID BLOCKS IN THE Z DIRECTION FOR ALL CELLS

Description

DZ defines the size of all grid blocks in the Z direction via an array for each cell in a Cartesian Regular Grid model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DZ	DZ is an array of real numbers describing the cell size in the Z direction for each cell in the model. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	None
Notes: 1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement. 2) The keyword is terminated by a "/".					

Table 6.31: DZ Keyword Description

See also the DX, DY and TOPS keywords to fully define a Cartesian Regular Grid.

Example

```
--
--        DEFINE GRID BLOCK Z DIRECTION CELL SIZE (BASED ON NX x NY x NZ = 300)
--
DZ
          100*20.0   100*30.0   100*50.0                                        /
```

The above example defines the size of the cells in the Z direction based on 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.52 DZMATRIX - MATRIX BLOCK HEIGHT FOR GRAVITY DRAINAGE MODEL FOR ALL CELLS

Description

The DZMATRIX keyword defines the matrix block height for the gravity drainage model by grid block for when the Dual Permeability or Dual Porosity models are activated by the DUALPERM and DUALPORO keywords and the Gravity Drainage option is invoked via the GRAVDR and GRAVDRM keywords. All keywords are in the RUNSPEC section.

The keyword is identical to the DZMTRXV keyword in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.53 DZMTRX - MATRIX BLOCK HEIGHT FOR GRAVITY DRAINAGE MODEL FOR THE GRID

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DZMTRX keyword defines a constant matrix block height for the gravity drainage model for the entire grid for when the Dual Permeability or Dual Porosity models are activated by the DUALPERM and DUALPORO keywords and the Gravity Drainage option is invoked via the GRAVDR and GRAVDRM keywords. All keywords are in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.54 DZMTRXV - MATRIX BLOCK HEIGHT FOR GRAVITY DRAINAGE MODEL FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DZMATRIX keyword defines the matrix block height for the gravity drainage model by grid block for when the Dual Permeability or Dual Porosity models are activated by the DUALPERM and DUALPORO keywords and the Gravity Drainage option is invoked via the GRAVDR and GRAVDRM keywords. All keywords are in the RUNSPEC section.

The keyword is identical to the DZMATRIX keyword in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.55 DZNET – DEFINE GRID BLOCK NET THICKNESS FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

DZNET defines the net thickness of all grid blocks in the Z direction via an array for each cell in a Cartesian Regular Grid model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DZNET	DZNET is an array of real numbers describing the net thickness in the Z direction for each cell in the model. Repeat counts may be used, for example 10*100.0. If the value for a grid block is not defined then the grid block size (DZ) is assigned to the missing values.			
		feet	m	cm	DZ

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.32: DZNET Keyword Description

See also the DX, DY, DZ, NTG and TOPS keywords to fully define a Cartesian Regular Grid.

Example

```
--
--       DEFINE GRID BLOCK Z DIRECTION NET THICKNESS(BASED ON NX x NY x NZ = 300)
--
DZNET
         100*15.0   100*25.0   00*45.0                                          /
```

The above example defines the net thickness of the cells in the Z direction based on 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.56 DZV - DEFINE THE SIZE OF GRID BLOCKS IN THE Z DIRECTION VIA A VECTOR

Description

DZV defines the size of grid blocks in the Z direction via a vector as opposed to defining the thickness property for each cell. The keyword is used for both Cartesian Regular Grids and Radial Grids.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DZV	DZV is a vector of real numbers describing the cell size for the grid blocks in the Z direction. Repeat counts may be used, for example 10*20.0.			
		feet	m	cm	None
Notes: 1) The number of entries should correspond to the NZ parameter on the DIMENS keyword in the RUNSPEC section.. 2) The keyword is terminated by a "/".					

Table 6.33: DZV Keyword Description

See also the DXV, DXY and TOPS keywords for a Cartesian Regular Grid and DRV, DTHETAV and TOPS keywords to fully define a Radial Grid model.

Example

```
--
--        DEFINE GRID BLOCK SIZES IN THE Z DIRECTION (BASED ON NZ = 20)
--
DZV
          3.0   5.0   3.0   2.0   5.0  15*3.0                                  /
```

The above example defines the size of the cells in the Z direction based on NZ equals 20 on the DIMENS keyword in the RUNSPEC section.

6.3.57 ECHO – ACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns on echoing of all the input files to the print file; note that this keyword is activated by default and can subsequently be switched off by the NOECHO activation keyword.

See *ECHO – Activate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

6.3.58 END – DEFINE THE END OF THE INPUT FILE

This keyword marks the end of the input file and can occur in any section. Any keywords and data after the END keyword are ignored.

See *END – Define the End of the Input File* in the GLOBAL section for a full description.

6.3.59 ENDBOX – DEFINE THE END OF THE BOX DEFINED GRID

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword marks the end of a previously defined BOX sub-grid as defined by a previously entered BOX keyword. The keyword resets the input grid to be the full grid as defined by the NX, NY, and NZ variables on the DIMENS keyword in the RUNSPEC section.

There is no data required for this keyword.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--
--       DEFINE GRID BLOCK PERMZ DATA FOR THE INPUT BOX
--
PERMZ
         6*0.01                                          /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a subset of the grid and sets the cells PERMZ values to 0.01 for that area. After which the ENDBOX keyword resets the input to be the full grid.

Note

It is good practice to always use the ENDBOX keyword to reset the input back to the full grid when all the modifications for a sub-grid have been completed.

6.3.60 ENDFIN – END THE DEFINITION OF A LOCAL GRID REFINEMENT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ENDFIN keyword defines the end of a Cartesian or radial local grid refinement ("LGR") definition and a LGR property definition data set. In the GRID section the CARFIN, RADFIN, and RADFIN4 keywords defines the start of an LGR description section, whereas the REFINE keyword in the EDIT, PROPS, REGIONS, SOLUTION and SCHEDULE section defines the start. The REFINE keyword can also be used in the GRID section provided the LGR has been previously specified by the CARFIN, RADFIN, or RADFIN4 keywords.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

The example below is based on using the CARFIN keyword in the GRID section to define an LGR in the global grid, named LGR-OP01 with a maximum of one well allowed in the LGR.

```
--
--        CARFIN LGR GRID COMMANDS
--
--        LGR         ----- FINE GRID ------    -- CARFIN GRID --   MAX      HOST
--        NAME        I1   I2   J1   J2   K1   K2     NX     NY     NZ    WELLS    NAME
CARFIN
          LGR-OP01    24   24   87   87    1   50      3      3     50      1      GLOBAL /

ENDFIN
```

Here the one global cell in the areal plane (24, 87) is divided into three LGR cells in the x-direction and three cells in the y-direction. Since no other property data is given, then the LGR cells take their properties from the host grid, that is the global grid.

6.3.61 ENDINC – DEFINE THE END OF AN INCLUDE FILE

This keyword marks the end of an include file specified on the INCLUDE keyword. When the ENDINC keyword is encountered in the INCLUDE file, input data is read from the next keyword in the current file. Any keywords and data after the ENDINC keyword in the INCLUDE file are ignored.

See *ENDINC – Define the End of an Include File* in the GLOBAL section for a full description.

6.3.62 ENDSKIP – DEACTIVATE SKIPPING OF KEYWORDS AND INPUT DATA

Turns off skipping of keywords that was activated by the SKIP, SKIP100, or SKIP300 keywords. Note that for each SKIP keyword activated there must be a corresponding ENDSKIP keyword.

See *ENDSKIP – DeActivate Skipping of Keywords and Input Data* in the GLOBAL section for a full description.

6.3.63 EQLZCORN - MODIFY THE DEPTH OF THE CORNER-POINT DEPTH ARRAY

Description

The EQLZCORN keyword modifies the depth of a corner point of a grid block on the pillars defining the reservoir grid. The keyword can be only used be used with Irregular Corner-Point Grids.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.64 EQUALREG – SETS AN ARRAY TO A CONSTANT BY REGION NUMBER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The EQUALREG keyword sets a specified array to a constant for cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the EQUALREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the EQUALREG keyword is being used.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	ARRAY	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	CONSTANT	An integer or real value to be assigned to the ARRAY in the same units as the ARRAY property for a given REGION	0
3	REGION NUMBER	REGION NUMBER is a positive integer representing the region for which the CONSTANT in (2) should be applied	None
4	REGION ARRAY	The REGION ARRAY to use for applying the CONSTANT in (2) based on the REGION NUMBER in (3). REGION ARRAY can have the following values: 1) F for the FLUXNUM array 2) M for the MULTNUM array 3) O for the OPERNUM array	M

Notes:

1) Where the REGION NUMBER should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.34: EQUALREG Keyword Description

The applicable arrays for each section are defined in Table 6.35.

EQUALREG Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL	ENDNUM	PRESSURE		
DY	PORV	SWCR	EQLNUM	SWAT		
DZ	TRANX	SWU	FIPNUM	SGAS		
PERMX	TRANY	SGL	IMBNUM	RV		
PERMY	TRANZ	SGCR	MISCNUM	RS		
PERMZ	DIFFX	SGU	PVTNUM	TBLK		
MULTX	DIFFY	KRW	ROCKNUM	GI		

EQUALREG Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
MULTY	DIFFZ	KRO	SATNUM	OILAPI		
MULTZ	TRANR	KRG	WH2NUM	SALT		
DR	TRANTHT	PCG		GASCONC		
THETA	DIFFR	PCW		SOLVCONC		
PERMR	DIFFTHT			SOLVFRAC		
PERMTHT				SFOAM		
DZNET				SPOLY

MULTNUM						
MPANUM						
DIFFX						
DIFFY						
DIFFZ						
DIFFR						
DIFFTHT						

Table 6.35: EQUALREG Keyword Applicable Arrays by Section

Example

```
-- FIRST DEFINE MULTNUM ARRAYS FOR 10 X 10 X 20 MODEL
--
--       ARRAY     CONSTANT     ---------- BOX ---------
--                              I1  I2   J1  J2   K1  K2
EQUALS
        MULTNUM     1          1*  1*   1*  1*   1*  1*      / MULTNUM IN MODEL
        MULTNUM     2          1*  1*   1*  1*   6   6       / MULTNUM IN MODEL
        MULTNUM     3          1*  1*   1*  1*   10  10      / MULTNUM IN MODEL
/
--     NOW SET PORO AND PERMX BASED ON THE MULTNUM REGION NUMBER
--
--        SETS A CONSTANT TO AN ARRAY BASED ON A REGION NUMBER
--
--        ARRAY      CONSTANT  REGION   REGION ARRAY
--                   VALUE     NUMBER    M / F / O
EQUALREG
          PORO       0.200     1         M                  /
          PORO       0.150     2         M                  /
          PORO       0.120     3         M                  /
          PERMX    100.00      1         M                  /
          PERMX     75.00      2         M                  /
          PERMX     50.00      3         M                  /
/
```

The example first defines the MULTNUM array to 1 for all cells in the model, after which selected areas of model are assigned various MULTNUM integer values. The EQUALREG can then be invoked to set a constant values for the PORO and PERMX arrays for the various MULTNUM regions.

6.3.65 EQUALS – SETS A SPECIFIED ARRAY TO A CONSTANT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The EQUALS keyword sets a specified array or part of an array to a constant. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the EQUALS keyword is being used.

No.	Name	Description	Default
1	ARRAY	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	CONSTANT	An integer or real value that the ARRAY will be set to in the same units as the ARRAY property.	None
3	I1	A positive integer that defines the lower bound of the array in the I-direction to be modified must be greater than or equal to one and less than or equal to I2 and NX.	1
4	I2	A positive integer that defines the upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
5	J1	A positive integer that defines the lower bound of the array in the J-direction to be modified must be greater than or equal to one and less than or equal to J2 and NY.	1
6	J2	A positive integer that defines the upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
7	K1	A positive integer that defines the lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
8	K2	A positive integer that defines the upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.

2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.36: EQUALS Keyword Description

The applicable arrays for each section are defined in Table 6.37.

EQUALS Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL	ENDNUM	PRESSURE		
DY	PORV	SWCR	EQLNUM	SWAT		
DZ	TRANX	SWU	FIPNUM	SGAS		

EQUALS Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
PERMX	TRANY	SGL	IMBNUM	RV		
PERMY	TRANZ	SGCR	MISCNUM	RS		
PERMZ	DIFFX	SGU	PVTNUM	TBLK		
MULTX	DIFFY	KRW	ROCKNUM	GI		
MULTY	DIFFZ	KRO	SATNUM	OILAPI		
MULTZ	TRANR	KRG	WH2NUM	SALT		
DR	TRANTHT	PCG		GASCONC		
THETA	DIFFR	PCW		SOLVCONC		
PERMR	DIFFTHT			SOLVFRAC		
PERMTHT				SFOAM		
DZNET				SPOLY		
PORO						
NTG						
FLUXNUM						
MULTNUM						
MPANUM						
DIFFX						
DIFFY						
DIFFZ						
DIFFR						
DIFFTHT						

Table 6.37: EQUALS Keyword Applicable Arrays by Section

Note

Unlike the commercial simulator, using the EQUALS keyword to setup the structure of the grid using the DX, DY, DZ and TOPS keywords should be avoided as it may cause OPM Flow to prematurely fail during the initialization.

See the second example on the correct way to setup this type of grid.

Examples

The first example resets the PERMX, PERMY and PERMZ, arrays to 0.10, 0.10, and 0.01 for all cells in layer five, respectively.

```
--
--   ARRAY      CONSTANT       ---------- BOX ---------
-                              I1  I2   J1  J2   K1  K2
EQUALS
    PERMX      0.1000         1*  1*   1*  1*   5   5  / PERMX TO 0.10 IN LAYER 5
    PERMY      0.1000         1*  1*   1*  1*   5   5  / PERMY TO 0.10 IN LAYER 5
    PERMZ      0.0100         1*  1*   1*  1*   5   5  / PERMZ TO 0.01 IN LAYER 5
/
```

The second example illustrates how to correctly setup a Cartesian Regular Grid in OPM Flow, given the DIMENS keyword in the RUNSPEC section is set to:

```
--
--       MAX     MAX     MAX
--       NDIVIX  NDIVIY  NDIVIZ
DIMENS
         10       10      3                                                  /
```

and the following keywords in the GRID section:

```
--
--       ACTIVATE IRREGULAR CORNER-POINT GRID TRANSMISSIBILITIES
--
OLDTRAN
--
--       DEFINE GRID BLOCK X DIRECTION CELL SIZE (BASED ON NX = 5)
--
DX
         300*1000                                                           /
--
--       DEFINE GRID BLOCK Y DIRECTION CELL SIZE (BASED ON NY = 5)
--
DY
         300*1000                                                           /
--
--       DEFINE GRID BLOCK SIZES IN THE Z DIRECTION
--
DZ
         100*20  100*30  100*50                                             /
--
--       DEFINE GRID BLOCK TOPS FOR THE TOP LAYER
--
TOPS
         100*8325                                                           /
--
--       ARRAY    CONSTANT        ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         PERMX     500.000        1*  1*   1*  1*    1   1 / Layer #01 Properties
         PERMY     500.000                                  /
         PERMZ      20.000                                  /
         PORO        0.300                                  /
         NTG         1.000                                  /

         PERMX      50.000        1*  1*   1*  1*    2   2 / Layer #02 Properties
         PERMY      50.000                                  /
         PERMZ      50.000                                  /
         PORO        0.300                                  /
         NTG         1.000                                  /

         PERMX     200.000        1*  1*   1*  1*    3   3 / Layer #03 Properties
         PERMY     200.000                                  /
         PERMZ     200.000                                  /
         PORO        0.300                                  /
         NTG         1.000                                  /
/
```

Notice that the DX, DY, DZ and TOPS keywords are defined separately, that is they are not included in the EQUALS keyword.

6.3.66 EXTFIN - DEFINE AN EXTERNAL UNSTRUCTURED LOCAL GRID REFINEMENT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The EXTFIN keyword defines an external Unstructured Local Grid Refinement ("LGR") in a cell or a group of cells in the global grid, and for when LGRs have been activated for the model using the LGR keyword in the RUNSPEC section. Note the global grid can be either structured, see the EXTREPL keyword in the GRID section for global structure grids, or unstructured, see the EXTHOST keyword in the GRID section for unstructured global grids.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.67 EXTHOST - DEFINE HOST CELLS FOR EXTERNAL LGRS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The EXTHOST keyword defines the host global grid blocks for an external Local Grid Refinement ("LGR") for when LGRs have been activated for the model using the LGR keyword in the RUNSPEC section, and the global grid is an unstructured grid.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.68 EXTRAPMS – ACTIVATE EXTRAPOLATION WARNING MESSAGES

The EXTRAPMS keyword activates extrapolation warning messages for when OPM Flow extrapolates the PVT or VFP tables. Frequent extrapolation warning messages should be investigated and resolved as this would indicate possible incorrect data and may result in the simulator extrapolating to unrealistic values.

See *EXTRAPMS – Activate Extrapolation Warning Messages* in the GLOBAL section for a full description.

6.3.69 EXTREPGL - DEFINE HOST CELLS FOR EXTERNAL UNSTRUCTURED LGRS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The EXTREPGL keyword defines the host global grid blocks for an external Unstructured Local Grid Refinement ("LGR") for when LGRs have been activated for the model using the LGR keyword in the RUNSPEC section, and the global grid is a structured grid.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.70 FAULTS – DEFINE FAULTS IN THE GRID GEOMETRY

Description

The FAULTS keyword defines the faults in the grid geometry and the keyword is normally exported with the grid geometry COORD and ZCORN data sets from static earth modeling software. Note that the FAULTS keyword is not required to describe the structural geometry as this is already accounted for in the COORD and ZCORN data sets, but instead lists the fault traces with respect to the grid. Once the fault traces have been defined with the FAULTS keyword then the fault transmissibilities can be modified by the MULTFLT keyword. Note that without the FAULTS keyword one would still get proper cross-fault transmissibilities but they would not be modifiable using MULTFLT keyword.

No.	Name	Description	Default
1	FLTNAME	FLTNAME is a character string enclosed in quotes with a maximum length of eight characters, that defines the name of the fault.	None
2	I1	The lower bound of the fault's I-direction range must be greater than or equal to one and less than or equal to I2 and NX.	None
3	I2	The upper bound of the fault's I-direction range must be greater than or equal to I1 and less than or equal to NX	None
4	J1	The lower bound of the fault's J-direction range must be greater than or equal to one and less than or equal to J2 and NY.	None
5	J2	The upper bound of the fault's J-direction range must be greater than or equal to J1 and less than or equal to NY.	None
6	K1	The lower bound of the fault's K-direction range must be greater than or equal to one and less than or equal to K2 and NZ.	None
7	K2	The upper bound of the fault's K-direction range must be greater than or equal to K1 and less than or equal to NZ.	None
8	FLTFACE	FLTFACE is a character string enclosed in quotes with a maximum length of two characters, that classifies the fault face. 1) If TRANMULT on the GRIDOPTS keyword in the RUNSPEC section is set to NO then FLTFACE can have values of X, Y, or Z. 2) Alternatively, if TRANMULT on the GRIDOPTS keyword in the RUNSPEC section is set to YES then FLTFACE can have values of X, Y, or Z for the positive direction, or X-, Y- or Z- for the negative direction transmissibilities.	None

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) The FAULTDIM keyword in the RUNSPEC defines the maximum number of records (or segments) that can be entered with the FAULTS keyword.
3) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.38: FAULTS Keyword Description

Example

The example below defines two fault traces, the first being the 'M_WEST' fault and the second the 'BC' fault trace.

```
--
--        DEFINE FAULTS IN THE GRID GEOMETRY
--
--        FAULT        ------------ FAULT TRACE -------------
--        NAME          I1   I2    J1   J2    K1   K2    FACE
FAULTS
          'M_WEST'       5    5     3    3     1    22    'X' /
          'M_WEST'       5    5     4    4     1    22    'X' /
          'M_WEST'       5    5     5    5     1    22    'X' /
          'M_WEST'       5    5     6    6     1    22    'X' /
          'M_WEST'       5    5     7    7     1    22    'X' /
          'M_WEST'       5    5     8    8     1    22    'X' /
          'M_WEST'       5    5     9    9     1    22    'X' /
          'M_WEST'       5    5    10   10     1    22    'X' /
          'M_WEST'       5    5    11   11     1    22    'X' /
……….……..

          'BC'          43   43     8    8     1    22   'Y'  /
          'BC'          42   42     9    9     1    22   'X'  /
          'BC'          44   44     8    8     1    22   'Y'  /
          'BC'          45   45     8    8     1    22   'Y'  /
          'BC'          46   46     8    8     1    22   'Y'  /
          'BC'          31   31     9    9     1    22   'Y'  /
          'BC'          30   30    10   10     1    22   'X'  /
          'BC'          32   32     9    9     1    22   'Y'  /
          'BC'          33   33     9    9     1    22   'Y'  /
          'BC'          34   34     9    9     1    22   'Y'  /
          'BC'          35   35     9    9     1    22   'Y'  /
          'BC'          36   36     9    9     1    22   'Y'  /
          'BC'          37   37     9    9     1    22   'Y'  /
          'BC'          38   38     9    9     1    22   'Y'  /
          'BC'          39   39     9    9     1    22   'Y'  /
          'BC'          40   40     9    9     1    22   'Y'  /
……….……..
/
```

6.3.71 FILEUNIT – ACTIVATE UNIT CONSISTENCY CHECKING

Description

The FILEUNIT keyword defines the units of the data set, and is used to verify that the units in the input deck and any associated include files are consistent. The keyword does not provide for the conversion between different sets of units.

No.	Name	Description	Default
1	FILEUNIT	A character string that defines the units of the data set, and should be set to: 1) FIELD for field units, 2) METRIC for metric units, or 3) LAB for laboratory units	None
Notes: 1) No unit conversion is performed. 2) The keyword is terminated by a "/".			

Table 6.39: FILEUNIT Keyword Description

OPM Flow's behavior is controllable through the "UNIT_SYSTEM_MISMATCH" environment variable. The default behavior if the check fails (i.e., if one of the INCLUDE files has a unit system different from the main run specification) is to terminate the simulation with an error.

Example

```
--
--       ACTIVATE UNIT CONSISTENCY CHECKING
--
FILEUNIT
         FIELD                                                          /
```

The above example defines the data set units to be FIELD units.

6.3.72 FLUXNUM – DEFINE THE FLUX REGIONS

Description

The FLUXNUM keyword defines the flux region numbers for each grid block, as such there must be one entry for each cell in the model. The array is used with the Flux Boundary option to define the various flux regions; however, the Flux Boundary option has not been implemented in OPM Flow. In addition, the array can be used with the EQUALREG, ADDREG, COPYREG, MULTIREG, MULTREGP and MULTREGT keywords in calculating various grid properties in the GRID section. This facility has been implemented in OPM Flow.

No.	Name	Description	Default
1	FLUXNUM	FLUXNUM defines an array of positive integers assigning a grid cell to a particular flux region. The maximum number of flux regions is set by the MXNFLX variable on the REGDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.40: FLUXNUM Keyword Description

Examples

The example below sets three FLUXNUM regions for a 4 x 5 x 2 model.

```
--
--        DEFINE FLUXNUM REGIONS FOR ALL CELLS
--
FLUXNUM
          2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
          3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--        ARRAY     CONSTANT       ---------- BOX ---------
--                                 I1  I2   J1  J2   K1  K2
EQUALS
          FLUXNUM    1            1*  1*   1*  1*   1*  1* / SET REGION 1
          FLUXNUM    2            1   2    1   2    1   1  / SET REGION 2
          FLUXNUM    3            1   2    1   2    2   2  / SET REGION 3
/
```

6.3.73 FLUXREG – DEFINE ACTIVE FLUX REGIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FLUXREG is used in conjunction with the USEFLUX keyword in runs with have multiple flux regions, to reduce the number of flux regions, that is the keyword specifies which flux regions are active and which are not in the current run.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.74 FLUXTYPE – DEFINES THE FLUX BOUNDARY TYPE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FLUXTYPE keyword defines the type of flux boundary to be used in the run.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.75 FORMFEED – DEFINED THE PRINT FILE FORM-FEED CHARACTER

The FORMFEED keyword defines the form-feed character, or carriage control character, for the output print (*.PRT) run summary (*.RSM) files. The keyword should be place at the very top of the input file.

See *FORMFEED – Defined the Print File Form-Feed Character* in the GLOBAL section for a dull description.

6.3.76 GDFILE – LOAD A GRID FILE

Description

The GDFILE keyword loads a GRID file that contains the structural data for the grid as a set of topological cuboidal cells, and EGRID files that contain structural and property data. Note OPM Flow only supports reading in EGRID files at this time.

No.	Name	Description	Default
1	GRIDFILE	A character string enclosed in quotes that defines the GRID or EGRID file to be read in and be processed by OPM Flow. Again, OPM Flow only supports reading in EGRID files.	None
2	FMTOPT	A defined character string that defines the format of the GRID or EGRID file to be read and should be set to one of the following: 1) FORMATTED: If the file is formatted as ASCII i.e. a text file, as oppose to a binary file. The option can be abbreviated to just the letter F. 2) UNFORMATTED: If the file is in binary format, note this option can be abbreviated to just the letter U. If the variable FMTOPT is omitted then the default is for binary file input for the commercial simulator; whereas, OPM Flow derives FMTOPT from the file extension (*.EGRID or *.FEGRID), making FMTOPT superfluous.	U
Notes: 1) The keyword is terminated by a "/".			

Table 6.41: GDFILE Keyword Description

See also the GRIDFILE keyword in the GRID section for exporting the GRID and EGRID files from the current simulation run.

Examples

The first example shown below loads the NOR-OPM-A00-GRID.EGRID file in binary format from the same directory as the data file.

```
--
--        LOAD A GRID FILE
--
GDFILE
          'NOR-OPM-A00-GRID.EGRID'       /
```

The next example loads the same EGRID file one directory above from where the data file is located.

```
--
--        LOAD a GRID FILE
--
GDFILE
          '../NOR-OPM-A00-GRID.EGRID'   /
```

6.3.77 GDORIENT - DEFINE GRID ORIENTATION PARAMETERS

Description

This keyword defines the grid orientation parameters for post-processing applications.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

6.3.78 GETDATA – LOAD AND ASSIGN DATA ARRAY FROM INIT OR RESTART FILES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The GETDATA keyword loads a data array from a previously generated INIT or RESTART file and assigns the loaded array to either same array in the run or another property array.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.79 GRID - DEFINE THE START OF THE GRID SECTION OF KEYWORDS

Description

The GRID activation keyword marks the end of the RUNSPEC section and the start of the GRID section that defines the key grid property data for the simulator including the grid structure, porosity, permeability and other relevant grid property data.

There is no data required for this keyword.

Example

```
-- ==========================================================================
--
-- GRID SECTION
--
-- ==========================================================================
GRID
```

The above example marks the end of the RUNSPEC section and the start of the GRID section in the OPM Flow data input file.

6.3.80 GRIDFILE – SET THE GRID FILE OUTPUT OPTIONS

Description

This keyword controls the output of a standard GRID or extended GRID file, as well as the extensible EGRID file for post-processing applications. The extended and extensible GRID formats are comparable; however, the extensible GRID format is more compact and is the only format supported by OPM Flow.

No.	Name	Description	Default
1	NGRID	A positive integer that controls the output of the GRID geometry file: 0) - for no GRID file to be written out. 1) - for the standard GRID file to be written out. 2) - for the extended GRID file to be written out. Only the default value of zero is supported.	0
2	NEGRID	A positive integer that controls the output of the EGRID geometry file: 0) - for no extensible GRID file to be written out. 1) - for the extensible GRID file to be written out. Only the default value of one is supported.	1
Notes: 1) The keyword is terminated by a "/".			

Table 6.42: GRIDFILE Keyword Description

Example

```
--
--       GRID FILE OUTPUT OPTIONS
--       GRID    EGRID
--       OPTN    OPTN
GRIDFILE
         0       1                                                    /
```

The above example defines that no GRID file will be written out and that the extensible GRID (that is the EGRID geometry format) file will be produced. This is the only configuration that OPM Flow supports

6.3.81 GRIDUNIT – DEFINE THE GRID UNITS

Description

The GRIDUNIT keyword defines the units of the grid data. It is usually output by pre-processing software when exporting the grid geometry. The data is not used by OPM Flow intrinsically, but is merely written to the output EGRID file, as specified by the GRIDFILE keyword, for the use of post-processing software like OPM ResInsight.

No.	Name	Description	Default
1	GRIDUNIT	A character string that defines the units of the coordinates stated on the MAPAXES keyword, and should be set to: 1) FEET for field units, 2) METRES for metric units, or 3) CM for laboratory units.	METRES
2	MAPOPT	A character string that defines if the grid data are measured relative to the map, or relative to the origin as stated on the MAPAXES keyword. MAPOPT should either be left blank (the default) indicating the origin is relative to the origin on the MAPAXES keyword, or set equal to MAP measured relative to the map.	1*
Notes: 1) Note the alternative spelling METRES, that is METERS is not recognized. 2) The keyword is terminated by a "/".			

Table 6.43: GRIDUNIT Keyword Description

Example

```
--
--       SET THE GRID UNITS FOR THE GRID
--
GRIDUNIT
         METRES                                                    /
```

The above example defines that the GRID units to be metric.

6.3.82 HALFTRAN – ACTIVATE HALF BLOCK TRANSMISSIBILITY CALCULATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HALFTRAN keyword activates the half block transmissibility calculation option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.83 HEATCR – DEFINE RESERVOIR ROCK HEAT CAPACITY FOR ALL CELLS

Description

The HEATCR keyword defines the reservoir rock volumetric heat capacity for all cells for when OPM Flow's thermal calculation is activated by the THERMAL keywords in the RUNSPEC section.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	HEATCR	HEATCR is an array of real positive numbers that define reservoir rock volumetric heat capacity of a grid block. Repeat counts may be used, for example 3000*25.0			
		Btu/ft3/°R	kJ/m3/K	J/cm3/K	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.44: HEATCR Keyword Description

Note this keyword is incompatible with SPECROCK keyword in the PROPS section.

Example

```
--
--       DEFINE GRID BLOCK RESERVOIR ROCK HEAT CAPACITY
--       FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--       KEYWORD IS INCOMPATIBLE WITH THE SPECROCK KEYWORD
--       (OPM FLOW THERMAL OPTION ONLY)
--
HEATCR
         300*32.0                                                    /
```

The above example defines the reservoir rock volumetric heat capacity of 32.0 for each cell in the 300 grid block model.

6.3.84 HEATCRT – DEFINE RESERVOIR ROCK HEAT CAPACITY TEMPERATURE DEPENDENCE FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HEATCRT keyword defines the reservoir rock volumetric heat capacity temperature dependence for all cells for when OPM Flow's thermal calculation is activated by the THERMAL keywords in the RUNSPEC section.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	HEATCRT	HEATCRT is an array of real positive numbers that define reservoir rock volumetric heat capacity temperature dependence of a grid block. Repeat counts may be used, for example 3000*0.05			
		Btu/ft3/°R2	kJ/m3/K2	J/cm3/K2	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.45: HEATCRT Keyword Description

Note this keyword is incompatible with SPECROCK keyword in the PROPS section.

The data for this keyword and the HEATCR keyword are used to calculate the reservoir rock volumetric heat capacity temperature dependence using the following relationship:

$$\text{Heat Capacity of Rock} = \text{HEATCR}\left(Temp - Temp_{ref}\right) + \frac{\text{HEATCRT}\left(Temp - Temp_{ref}\right)^2}{2} \quad (6.3)$$

Example

```
--
--       DEFINE RESERVOIR ROCK HEAT CAPACITY TEMPERATURE DEPENDENCE
--       FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--       KEYWORD IS INCOMPATIBLE WITH THE SPECROCK KEYWORD
--       (OPM FLOW THERMAL OPTION ONLY)
--
HEATCRT
         300*0.05                                                    /
```

The above example defines the reservoir rock volumetric heat capacity temperature dependence of 0.05 for each cell in the 300 grid block model.

6.3.85 HMAQUNUM - HISTORY MATCH NUMERICAL AQUIFER GRADIENT PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HMAQUNUM keyword defines the history match numerical aquifer gradient parameters for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section, and numerical aquifers have been specified in the model via the AQUNUM keyword and connected to the grid using AQUCON keyword. All keywords are in the GRID section.

See also the HMDIMS keyword in the RUNSPEC section that specifies the dimensions for the gradient option, including the maximum number of aquifers that can be used with the History Match Gradient option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.86 HMFAULTS – HISTORY MATCH FAULT GRADIENT PARAMETERS

Description

The HMFAULTS keyword defines the history match faults gradient parameters for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section, and for when the FAULTS keyword in the GRID section has been used to define faults in the model.

See also the HMDIMS keyword in the RUNSPEC section that specifies the dimensions for the gradient option, including the maximum number of faults that can be used with the History Match Gradient option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.87 HMMLAQUN – HISTORY MATCH NUMERICAL AQUIFER GRADIENT MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HMMLAQUN keyword defines the history match numerical aquifer gradient multipliers for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section, and numerical aquifers have been specified in the model via the AQUNUM keyword and connected to the grid using the AQUCON keyword. All keywords are in the GRID section.

Multipliers can be declared for numerical aquifers' pore volume, permeability, and aquifer to grid connection factors.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.88 HMMLT – HISTORY MATCH GRID PERMEABILITY GRADIENT CUMULATIVE MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HMMLT series of keywords defines the history match gradient cumulative permeability multipliers, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. The keyword consists of the first five characters of "HMMLT" followed by a two or three character string shown in Table 6.46, that determines the permeability direction, for example, HMMLTPX.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Mnemonic	Cartesian Grid		Radial Grid	
	Grid Keyword	HMMULT Keyword	Grid Keyword	HMMULT Keyword
PX/PR	PERMX	HMMLTPX	PERMR	HMMLTPR
PXY	PERMXY	HMMLTPXY		
PY/THT	PERMY	HMMLTPY	PERMTHT	HMMLTTH
PZ	PERMZ	HMMLTPZ	PERMZ	HMMLTPZ

Table 6.46: HMMLT Keyword List

See also the HMMULT keyword in the EDIT section

6.3.89 HMMMREGT - HISTORY MATCH REGION TRANSMISSIBILITY GRADIENT CUMULATIVE MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HMMMREGT keyword multiplies the transmissibility between two regions by a constant, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. The constant should be a real number. Unlike the MULTREGT keyword in the GRID section, the HMMMREGT keyword modifications are cumulative.

Note that the HMMMREGT keyword only declares the two regions and the multiplier between those regions, the transmissibility direction (DIR on the MULTREGT keyword), type of transmissibility multiplier (TYPE on the MULTREGT keyword), and the region number array to use (ARRAY on the MULTREGT keyword), are all taken from the MULTREGY keyword. For example, the region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGT keyword is read by the simulator, and before the HMMMREGT keyword is used.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

6.3.90 HMMULRGT – HISTORY MATCH REGION TRANSMISSIBILITY PARAMETERS

Description

HMMULRGT defines the transmissibility between two regions gradient parameters, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section.

See also the HMDIMS keyword in the RUNSPEC section that specifies the dimensions for the gradient option, including the maximum number of gradient regions that can be used with the History Match Gradient option.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

6.3.91 HMMULTFT – HISTORY MATCH FAULT TRANSMISSIBILITY GRADIENT CUMULATIVE MULTIPLIERS

Description

HMMULTFT defines the history match fault transmissibility gradient cumulative multipliers to be applied to the fault transmissibilities for faults declared by the FAULT keyword in the GRID section, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. The keyword allows for the re-scaling of the existing fault transmissibilities calculated by OPM Flow, or if the MULTFLT keyword has been entered, then HMMULTFT is applied to the existing MULTFLT multipliers.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.92 HMMULTSG – HISTORY MATCH DUAL POROSITY SIGMA GRADIENT CUMULATIVE MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HMMULTSG defines the history match dual porosity sigma parameter gradient cumulative multipliers applied to the dual porosity sigma value declared by the SIGMAV and SIGMAGDV keywords in the PROPS section, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. In addition to the HMDIMS keyword, either the DUALPERM keyword that activates the Dual Permeability option, or the DUALPORO keyword that activates the Dual Porosity option for the run, must be declared in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.93 HRFIN - DEFINE THE RATIO OF LGR GRID BLOCKS IN THE R-DIRECTION

Description

HRFIN[120] defines the ratio of grid blocks for the DRV keyword in the r-direction via a vector within a Local Grid Refinement ("LGR") as opposed to defining the size for each cell for a Radial LGR Grid. The LGR keyword in the RUNSPEC section should be activated to indicate an LGR is being used, and the keyword HRFIN should be placed in between the RADIN (or RAFDIN4) and ENDFIN keywords in the GRID section. The DRV keyword in the GRID section defines the radial grid size in terms of the length, that is feet for field units, this keyword defines the length as the ratio of the previous cell size, staring with the inner radius (INRAD).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	HRFIN	HRFIN is a vector of real numbers describing the ratio of cell size for the grid blocks in the r-direction in a radial LGR for the DRV keyword. Repeat counts may be used, for example 2*1.5.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NR parameter minus one on the RADFIN or RADFIN4 keywords in the GRID section

2) The keyword is terminated by a "/".

Table 6.47: HRFIN Keyword Description

See also the DR, DRV, DTHETAV, and DZ keywords in the GRID section to fully define a radial LGR model.

Example

```
--
--       INNER RADIUS OF FIRST GRID BLOCK IN THE RADIAL DIRECTION
--
INRAD    0.25                                                          /
--
--       DEFINE GRID BLOCK DRV RATIOS IN THE R DIRECTION
--
HRFIN
         1.50  2.00  3.00  5.00  7.00  10.00                           /
```

The above example defines the size of the cells in the R direction based on NR equals 7, resulting in NR-1 values on the RADFIN keyword in the GRID section. Note the INRAD keyword to define the inner radius of the radial grid.

[120] *Radial grids are not currently implemented in this version of OPM Flow, but is expected to be incorporated in a future release.*

6.3.94 HXFIN - DEFINE THE RATIO OF LGR GRID BLOCKS IN THE X-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HXFIN defines the split ratio of grid blocks for the DXV keyword in the x-direction via a vector within a Local Grid Refinement ("LGR") as opposed to defining the size for each cell for a Cartesian LGR Grid. The LGR keyword in the RUNSPEC section should be activated to indicate an LGR is being used, and the keyword HXFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section. The DXV keyword in the GRID section defines the grid size in terms of the length, that is feet for field units, this keyword defines the length as the ratio of the coarse cells.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	HXFIN	HXFIN is a vector of real numbers describing the ratio of cell size for the grid blocks in the x-direction in a Cartesian LGR grid. Repeat counts may be used, for example 2*2.0.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NX parameter on the CARFIN keyword in the GRID section.
2) The keyword is terminated by a "/".

Table 6.48: HXFIN Keyword Description

See also the CARFIN, ENDFIN, HYFIN, and HZFIN keywords in the GRID section to fully define a Cartesian LGR grid model.

Example

```
--
--       CARFIN LGR GRID COMMANDS
--
--       LGR        ----- HOST GRID ------    -- CARFIN GRID --   MAX     HOST
--       NAME       I1  I2  J1  J2  K1  K2     NX    NY    NZ   WELLS   NAME
CARFIN
         LGR-OP01   24  25  86  87   1  50      5     3    50     1     GLOBAL /
--
--       DEFINE LGR GRID BLOCK IN THE X-DIRECTION
NXFIN
         3  2                                                              /
--
--       DEFINE GRID BLOCK LGR RATIOS IN THE X-DIRECTION
--
HXFIN
         1.00  2.00  3.00  2.00  1.00                                      /
ENDFIN
```

The above example defines the size of the cells in the x-direction based on NX equals five on the CARFIN keyword in the GRID section.

6.3.95 HYFIN - DEFINE THE RATIO OF LGR GRID BLOCKS IN THE Y-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HYFIN defines the split ratio of grid blocks for the DYV keyword in the y-direction via a vector within a Local Grid Refinement ("LGR") as opposed to defining the size for each cell for a Cartesian LGR Grid. The LGR keyword in the RUNSPEC section should be activated to indicate an LGR is being used, and the keyword HYFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section. The DYV keyword in the GRID section defines the grid size in terms of the length, that is feet for field units, this keyword defines the length as the ratio of the coarse cells.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	HYFIN	HYFIN is a vector of real numbers describing the ratio of cell size for the grid blocks in the y-direction in a Cartesian LGR grid. Repeat counts may be used, for example 2*2.0.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NY parameter on the CARFIN keyword in the GRID section.
2) The keyword is terminated by a "/".

Table 6.49: HYFIN Keyword Description

See also the CARFIN, ENDFIN, HXFIN, and HZFIN keywords in the GRID section to fully define a Cartesian LGR grid model.

Example

```
--
--       CARFIN LGR GRID COMMANDS
--
--       LGR        ----- HOST GRID ------    -- CARFIN GRID --   MAX     HOST
--       NAME       I1  I2  J1  J2  K1  K2     NX    NY    NZ   WELLS   NAME
CARFIN
         LGR-OP01   24  25  86  87   1  50      3     5    50     1     GLOBAL /
--
--       DEFINE LGR GRID BLOCK IN THE Y-DIRECTION
NYFIN
         3  2                                                              /
--
--       DEFINE GRID BLOCK LGR RATIOS IN THE Y-DIRECTION
--
HYFIN
         1.00  2.00  3.00  2.00  1.00                                      /
ENDFIN
```

The above example defines the size of the cells in the y-direction based on NY equals five on the CARFIN keyword in the GRID section.

6.3.96 HZFIN - DEFINE THE RATIO OF LGR GRID BLOCKS IN THE Z-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HZFIN defines the split ratio of grid blocks for the DZV keyword in the z-direction via a vector within a Local Grid Refinement ("LGR") as opposed to defining the size for each cell for a Cartesian LGR Grid. The LGR keyword in the RUNSPEC section should be activated to indicate an LGR is being used, and the keyword HYFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section. The DZV keyword in the GRID section defines the grid size in terms of the length, that is feet for field units, this keyword defines the length as the ratio of the coarse cells.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	HYZIN	HZFIN is a vector of real numbers describing the ratio of cell size for the grid blocks in the z-direction in a Cartesian LGR grid. Repeat counts may be used, for example 2*2.0.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NZ parameter on the CARFIN keyword in the GRID section.
2) The keyword is terminated by a "/".

Table 6.50: HZFIN Keyword Description

See also the CARFIN, ENDFIN, HXFIN, and HYFIN keywords in the GRID section to fully define a Cartesian LGR grid model.

Example

```
--
--       CARFIN LGR GRID COMMANDS
--
--       LGR        ----- HOST GRID ------    -- CARFIN GRID --   MAX     HOST
--       NAME       I1  I2  J1  J2  K1  K2     NX    NY    NZ   WELLS   NAME
CARFIN
         LGR-OP01   24  25  86  87   1  50      5     3    100    1     GLOBAL /
--
--       DEFINE LGR GRID BLOCK IN THE Z-DIRECTION
NZFIN
         50*2                                                              /
--
--       DEFINE GRID BLOCK LGR RATIOS IN THE Z-DIRECTION
--
HZFIN
         50*2.0                                                            /
ENDFIN
```

The above example defines the size of the cells in the z-direction based on NZ equals 100 on the CARFIN keyword in the GRID section.

6.3.97 IHOST – ASSIGN LGRS TO PARALLEL PROCESS NUMBER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The IHIST keyword assigns Local Grid Refinements ("LGR") to a parallel process number, for when the PARALLEL keyword has been invoked in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.98 IMPORT – IMPORT GRID FILE DATA AT THE CURRENT POSITION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The IMPORT keyword informs the simulator to import data from the specified IMPORT file. When the end of the IMPORT file is reached, input data is read from the next keyword in the current file. Normally IMPORT files are generated by grid pre-processing software and the keyword allows for both formatted and unformatted (binary) files to be loaded. The keyword can be used to import any valid grid arrays within a section, for example the EQLNUM array in the REGIONS section

No.	Name	Description	Default
1	FILENAME	A character string enclosed in quotes that defines a file to be imported and to be processed by OPM Flow.	None
2	FMTOPT	A defined character string that defines the format of the file to be imported and should be set to one of the following: 1) FORMATTED: If the file is formatted as ASCII i.e. a text file, as oppose to a binary file. The option can be abbreviated to just the letter F. 2) UNFORMATTED: If the file is in binary format, note this option can be abbreviated to just the letter U. If the variable FMTOPT is omitted then the default is for binary file input.	U
Notes: 1) The keyword is terminated by a "/".			

Table 6.51: IMPORT Keyword Description

Examples

The first example shown below loads the grid file from the same directory as the data file.

```
--
--       LOAD A IMPORT FILE
--
IMPORT
         'NOR-OPM-A00-GRID.EGRID'  /
```

The next example loads the same file one directory above from where the data file is located.

```
--
--       LOAD A IMPORT FILE
--
IMPORT
         '../NOR-OPM-A00-GRID.EGRID'  /
```

The final example loads the same file from a separate include subdirectory in the parent directory of the data file.

```
--
--       LOAD A IMPORT FILE
--
IMPORT
         '../INCLUDE/NOR-OPM-A00-GRID.EGRID'  /
```

6.3.99 INCLUDE – LOAD ANOTHER DATA FILE AT THE CURRENT POSITION

The INCLUDE keyword informs OPM Flow to continue reading input data from the specified INCLUDE file. When the end of the INCLUDE file is reached, or the ENDINC keyword is encountered in the included file, input data is read from the next keyword in the current file.

See *INCLUDE – Load Another Data File at the Current Position* in the GLOBAL section for a full description.

6.3.100 INIT – ACTIVATE THE INIT FILE OPTION

Description

This keyword switches on the writing of the INIT file that contains the static data specified in the GRID, PROPS and REGIONS sections. For example, the PORO, PERM and NTG arrays from the GRID section. The data is used in post-processing software, for example OPM ResInsight, to visualize the static grid properties.

The INIT file can either be written out in formatted form as ASCII i.e. text files, if the FMTOUT keyword has been activated, or binary format if the FMTOUT keyword has not been activated. Normally, this option is always activated by the user and when activated the binary form of the file is used.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE WRITING THE INIT FILE FOR POST-PROCESSING
INIT
```

The above example switches on the writing of the INIT file for post-processing in ResInsight.

6.3.101 INRAD – DEFINE THE INNER RADIUS OF A RADIAL GRID

Description

INRAD defines the inner radius of the reservoir model for a radial grid geometry. The RADIAL or SPIDER keyword in the RUNSPEC should be activated to indicate that radial geometry is being used.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	INRAD	A single real positive number defining the inner radius of a radial grid.			
		feet	m	cm	None
Notes: 1) The keyword is terminated by a "/".					

Table 6.52: INRAD Keyword Description

Note that the SPIDER keyword activates OPM Flow's radial grid geometry option for the model. This keyword will create a spiderweb-shaped grid based on a corner-point grid using the standard radial grid keywords: INRAD, DRV, DTHETAV, DZ/DZV etc. in the GRID the section. A spider grid can be viewed in 3D in OPM ResInsight unlike radial grids that cannot be viewed in the software. To overcome this, the simulator now converts radial grids to Irregular Corner-Point Grids and adjusts the model's pore volume to reflect radial coordinates; thus, overcoming the display limitation.

See also the DR, DRV, DTHETA, DTHETAV and TOPS keywords to fully define a radial or spider grid in the model.

Example

```
--
--       INNER RADIUS OF FIRST GRID BLOCK IN THE RADIAL DIRECTION
--
INRAD
         0.25                                                                  /
```

The above example defines the inner radius of a radial grid to be 0.25 feet.

6.3.102 IONROCK – DEFINE THE ION EXCHANGE CAPACITY FOR ALL THE CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The IONROCK keyword defines the ion exchange capacity for all the cells in the model, for when the brine phase has been activated by the BRINE keyword and the Multi-Component Brine model, that allows for the water phase to have multiple water salinities, has been activated by the ECLMC keyword. Both keywords are in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.103 ISOLNUM – DEFINE THE INDEPENDENT RESERVOIR REGIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ISOLNUM keyword defines areas of the grid that consists of isolated reservoirs where the only form of communication between the reservoirs is via wellbore connections This enables the reservoir flow equations to be solved independently for greater computational efficiency.

No.	Name	Description	Default
1	ISOLNUM	ISOLNUM defines an array of positive integers assigning a grid cell to a particular isolated reservoir region. The maximum number of ISOLNUM regions is set by the NRFREG variable on the REGDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) Setting ISOLNUM for a cell to zero makes the cell inactive.
3) The keyword is terminated by a "/".

Table 6.53: ISOLNUM Keyword Description

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

The example below defines three separate independent reservoirs; the first reservoir covers the whole grid and layers 1 to 50, reservoir two cover the whole grid and layers 52 to 150, and finally the third reservoir again covers the whole grid but with layers 152 to 300. The layers 51 and 151 are shale layers made inactive by setting ISOLNUM to zero.

```
--
--        ARRAY     CONSTANT       ---------- BOX ---------
--                                 I1  I2   J1  J2   K1  K2
EQUALS
          ISOLNUM    1             1*  1*   1*  1*   1   50 / DEFINED RESERVOIR 1
          ISOLNUM    0             1*  1*   1*  1*   51  51 / DEFINED A SHALE
          ISOLNUM    2             1*  1*   1*  1*   52 150 / DEFINED RESERVOIR 2
          ISOLNUM    0             1*  1*   1*  1*  151 151 / DEFINED A SHALE
          ISOLNUM    3             1*  1*   1*  1*  152 300 / DEFINED RESERVOIR 3
/
```

Note the above example has no effect as the keyword is ignored by the simulator.

6.3.104 JFUNC - ACTIVATE THE LEVERETT J-FUNCTION OPTION

Description

The JFUNC keyword activates the Leverett-J-Function[121] option which is a commonly used technique to normalize capillary pressure based on laboratory measured core plugs porosity and permeability values and the resulting capillary pressure data. The keyword performs the calculation based on the parameters on the this keyword combined with a cells porosity and permeability to perform the scaling globally.

The keyword should only be used if end-point scaling is switched on using the ENDSCALE keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	JFOPT	A character string that defines which capillary data sets the J-Function option should be applied to, based on the following options: 1) WATER: apply the J-Function option to the water-oil capillary pressure data only. 2) GAS: apply the J-Function option to the gas-oil capillary pressure data only. 3) BOTH: apply the J-Function option to the water-oil and the gas-oil capillary pressure data.			BOTH
2	OWSTEN	A positive real number that defines oil-water surface tension used to de-normalized J-Function data entered in the PROPS section.			
		dynes/cm	dynes/cm	dynes/cm	None
3	OGSTEN	A positive real number that defines oil-gas surface tension used to de-normalized J-Function data entered in the PROPS section.			
		dynes/cm	dynes/cm	dynes/cm	None
4	ALPHA	A positive real value that defines an alternative power value for the porosity term in the J-Function equation, that is instead of $\sqrt{\frac{k}{\varphi}}$ use $\frac{k^{0.5}}{\varphi^{\alpha}}$ instead in the transformation.			0.5
5	BETA	A positive real number that defines an alternative power value for the permeability term in the J-Function equation, that is instead of $\sqrt{\frac{k}{\varphi}}$ use $\frac{k^{\beta}}{\varphi^{0.5}}$ instead in the transformation.			0.5

[121] *Leverett, M. C.; "Capillary Behaviour in Porous Solids", Trans. AIME (1941) 142, 152-168.*

No.	Name	Description			Default
		Field	Metric	Laboratory	
6	PERM	PERM is a character string that sets the permeability array to be used in the transform, based on the following options: 1) X: use the PERMX array. 2) XY: use the average of the PERMX and PERMY arrays. 3) Y: use the PERMY array. 4) Z: use the PERMZ array. 5) U: use the PERMJFUN array			XY
Notes: 1) The keyword is terminated by a "/".					

Table 6.54: JFUNC Keyword Description

Just like the relative permeability data capillary pressure data are measured on core plugs with varying quality and perhaps from different reservoirs. It is therefore necessary to determine averaged data, before employing the data in engineering calculations. This is commonly done by using the Leverett J-function[122], which is defined as:

$$J\left(S_w\right) = \frac{P_{c,res}\left(S_w\right)\sqrt{\frac{k}{\varphi}}}{\sigma} \tag{6.4}$$

Where:

$J(S_w)$	=	dimensionless function of water saturation
$P_c(S_w)$	=	capillary pressure (kPa)
k	=	permeability, (m^2)
φ	=	porosity (fraction)
σ	=	interfacial tension (mN/m)
Θ	=	contact angle

Sometimes the equation is stated with the cos θ term included, that is:

$$J\left(S_w\right) = \frac{P_{c,res}\left(S_w\right)\sqrt{\frac{k}{\varphi}}}{\sigma\ \cos\ \Theta} \tag{6.5}$$

Since the above function is just a normalizing function, then units are not important, as long as when we de-normalize the *average* curve we use the same unit set. Secondly, if all the capillary pressure data has been converted to reservoir conditions, we actually ignore the denominator as it is a constant, and we can therefore just use:

$$J\left(S_w\right) = P_{c,res}\left(S_w\right)\sqrt{\frac{k}{\varphi}} \tag{6.6}$$

[122] *Leverett, M. C.; "Capillary Behaviour in Porous Solids", Trans. AIME (1941) 142, 152-168.*

However, in the simulator it is necessary to use the formal definition as outlined in equation (6.4). In addition to the standard the equation the keyword allows for de-normalizing the curve to use alternative power functions instead of the standard 0.5 used in equation (6.4), that is:

$$J\left(S_w\right) = \frac{P_{c,res}\left(S_w\right)\left(\frac{k^{\beta}}{\varphi^{\alpha}}\right)}{\sigma} \tag{6.7}$$

Where:

$J(S_w)$	=	dimensionless function of water saturation
$P_c(S_w)$	=	capillary pressure (kPa)
k	=	permeability, (m^2)
φ	=	porosity (fraction)
σ	=	interfacial tension (mN/m)
Θ	=	contact angle
α	=	porosity power value
β	=	permeability value

The JFUNC keyword allows the data entered as capillary pressure in the saturation tables, for example, by using the SGFN and SWFN keywords in the PROPS section to be treated as J-functions instead, and to de-normalize these curves for each active cell in the model using the options and values defined with the JFUNC keyword combined with a cells porosity and permeability values.

Note

If either the JFUNC or JFUNCR keywords are used to activate J-Function scaling then the ENDSCALE keyword in the RUNSPEC section must also be present in the input deck, in order for the dimensionless J-function values entered on the SWFN, SGFN or the SWOF, SGOF, SLGOF keywords to be re-scaled to capillary pressure data.

Note if the ENDSCALE keyword is absent, then like the commercial simulator, J-Function scaling is not performed, and the values entered on the SWFN, SGFN or the SWOF, SGOF, SLGOF keywords are used as entered.

See also the JFUNCR keyword in the GRID section that performs similar calculations based on the J-Function parameters being declared by saturation table number.

Example

```
--
--       DEFINE LEVERETT J-FUNCTION PARAMETERS
--       JFUN    OILWAT  GASOIL  PORO    PERM    PERM
--       OPTN    SDENS   SDEN    ALPHA   BETA    OPTN
JFUNC
         WATER   22.5    1*      0.5     0.5     XY                    /
```

The above example results in the oil-water capillary pressure data entered on the SWFN keyword in the PROPS section being treated as J-Functions, and that the J-Function should be de-normalized using an oil-water surface density of 22.5 dynes/cm, using the default power values and the average of the PERMX and PERMY values for each grid block.

6.3.105 JFUNCR - ACTIVATE THE LEVERETT J-FUNCTION SATURATION TABLE OPTION

Description

JFUNCR keyword activates Leverett-J-Function[123] Saturation Table option which is a commonly used technique to normalize capillary pressure base on laboratory measured core plugs porosity and permeability values and the resulting capillary pressure data. This keyword is an extension of the JFUNC keyword in the GRID section that uses the parameters on the JFUNC keyword combined with a cell's porosity and permeability to perform the scaling globally. In comparison, the JFUNCR allows for the J-Function parameters to be declared per saturation table number, resulting in greater flexibility.

The keyword should only be used if end-point scaling is switched on using the ENDSCALE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	JFOPT	A character string that defines which capillary data sets the J-Function option should be applied to, based on the following options: 1) WATER: apply the J-Function option to the water-oil capillary pressure data only. 2) GAS: apply the J-Function option to the gas-oil capillary pressure data only. 3) BOTH: apply the J-Function option to the water-oil and the gas-oil capillary pressure data.			BOTH
2	OWSTEN	A positive real number that defines oil-water surface tension used to de-normalized J-Function data entered in the PROPS section.			
		dynes/cm	dynes/cm	dynes/cm	None
3	OGSTEN	A positive real number that defines oil-gas surface tension used to de-normalized J-Function data entered in the PROPS section.			
		dynes/cm	dynes/cm	dynes/cm	None
4	ALPHA	A positive real value that defines an alternative power value for the porosity term in the J-Function equation, that is instead of $\sqrt{\frac{k}{\varphi}}$ use $\frac{k^{0.5}}{\varphi^{\alpha}}$ instead in the transformation.			0.5
5	BETA	A positive real number that defines an alternative power value for the permeability term in the J-Function equation, that is instead of $\sqrt{\frac{k}{\varphi}}$ use $\frac{k^{\beta}}{\varphi^{0.5}}$ instead in the transformation.			0.5

[123] *Leverett, M. C.; "Capillary Behaviour in Porous Solids", Trans. AIME (1941) 142, 152-168.*

No.	Name	Description			Default
		Field	Metric	Laboratory	
6	PERM	PERM is a character string that sets the permeability array to be used in the transform, based on the following options: 1) X: use the PERMX array. 2) XY: use the average of the PERMX and PERMY arrays. 3) Y: use the PERMY array. 4) Z: use the PERMZ array. 5) U: use the PERMJFUN array			XY
Notes: 1) The keyword is followed by exactly NTSFUN rows of data, as declared on the TABDIMS keyword in the RUNSPEC section. 2) Each row is terminated by a "/" and there is no "/" terminator for the keyword.					

Table 6.55: JFUNCR Keyword Description

Just like the relative permeability data capillary pressure data are measured on core plugs with varying quality and perhaps from different reservoirs. It is therefore necessary to determine averaged data, before employing the data in engineering calculations. This is commonly done by using the Leverett J-function[124], which is defined as:

$$J\left(S_w\right) = \frac{P_{c,res}\left(S_w\right)\sqrt{\frac{k}{\varphi}}}{\sigma} \tag{6.8}$$

Where:

$J(S_w)$	=	dimensionless function of water saturation
$P_c(S_w)$	=	capillary pressure (kPa)
k	=	permeability, (m^2)
φ	=	porosity (fraction)
σ	=	interfacial tension (mN/m)
Θ	=	contact angle

Sometimes the equation is stated with the cos θ term included, that is:

$$J\left(S_w\right) = \frac{P_{c,res}\left(S_w\right)\sqrt{\frac{k}{\varphi}}}{\sigma\ \cos\ \Theta} \tag{6.9}$$

Since the above function is just a normalizing function, then units are not important, as long as when we de-normalize the *average* curve we use the same unit set. Secondly, if all the capillary pressure data has been converted to reservoir conditions, we can actually ignore the denominator as it is a constant, and we can therefore just use:

$$J\left(S_w\right) = P_{c,res}\left(S_w\right)\sqrt{\frac{k}{\varphi}} \tag{6.10}$$

[124] *Leverett, M. C.; "Capillary Behaviour in Porous Solids", Trans. AIME (1941) 142, 152-168.*

However, in the simulator it is necessary to use the formal definition as outlined in equation (6.8). In addition to the standard the equation the keyword allows for de-normalizing the curve to use alternative power functions instead of the standard 0.5 used in equation (6.8), that is:

$$J\left(S_w\right) = \frac{P_{c,res}\left(S_w\right)\left(\frac{k^{\beta}}{\varphi^{\alpha}}\right)}{\sigma} \tag{6.11}$$

Where:

$J(S_w)$	=	dimensionless function of water saturation
$P_c(S_w)$	=	capillary pressure (kPa)
k	=	permeability, (m^2)
φ	=	porosity (fraction)
σ	=	interfacial tension (mN/m)
Θ	=	contact angle
α	=	porosity power value
β	=	permeability value

The JFUNC keyword allows the data entered as capillary pressure in the saturation tables, for example, by using the SGFN and SWFN keywords in the PROPS section to be treated as J-functions instead, and to de-normalize these curves for each active cell in the model using the options and values defined with the JFUNC keyword combined with a cells porosity and permeability values.

Note

If either the JFUNC or JFUNCR keywords are used to activate J-Function scaling then the ENDSCALE keyword in the RUNSPEC section must also be present in the input deck, in order for the dimensionless J-function values entered on the SWFN, SGFN or the SWOF, SGOF, SLGOF keywords to be re-scaled to capillary pressure data.

Note if the ENDSCALE keyword is absent, then like the commercial simulator, J-Function scaling is not performed, and the values entered on the SWFN, SGFN or the SWOF, SGOF, SLGOF keywords are used as entered.

See also the JFUNC keyword in the GRID section that uses the parameters on the JFUNC keyword combined with a cell's porosity and permeability to perform the scaling globally.

Example

The example below assumes NTSFUN is equal to five on the TABDIMS keyword in the RUNSPEC section.

```
--
--       DEFINE LEVERETT J-FUNCTION PARAMETERS BY SATURATION TABLES
--       JFUN    OILWAT  GASOIL  PORO    PERM    PERM
--       OPTN    SDENS   SDEN    ALPHA   BETA    OPTN
JFUNCR
         WATER   22.5    1*      0.5     0.5     XY                    /
         WATER   22.5    1*      0.5     0.5     XY                    /
         WATER   22.5    1*      0.5     0.5     XY                    /
         WATER   22.5    1*      0.5     0.5     XY                    /
         WATER   22.5    1*      0.5     0.5     XY                    /
```

Here the oil-water capillary pressure data entered on the SWFN keyword in the PROPS section are treated as J-Functions, and that the J-Function should be de-normalized using an oil-water surface density of 22.5 dynes/cm, using the default power values and the average of the PERMX and PERMY values for each grid block, for all five tables. Note that since all the JFUNCR parameters are the same for all saturation tables then the JFUNC keyword could be used instead in this instance.

6.3.106 LGRCOPY – ACTIVATE LOCAL GRID REFINEMENT INHERITANCE

The LGRCOPY keyword actives Local Grid Refinement ("LGR") Inheritance option that allows the LGR to inherit the properties of the global or host cell containing a LGR grid block at the start of the GRID section, as oppose to the normal process of applying this transform at the end of the GRID section. LGRCOPY can be used in the RUNSPEC, GRID and EDIT sections. If used in the RUNSPEC section then the option is applied to all LGRs defined in the input file, whereas if used in the GRID and EDIT sections the keyword must be placed inside a LGR definition section, that is between a CARFIN (Cartesian LGR grid) or RADIN/RADIN4 (radial LGR grid) and the ENDFIN keyword. In the latter case inheritance is applied on an individual LGR basis.

See *LGRCOPY – Activate Local Grid Refinement Inheritance* in the RUNSPEC section for a full description.

6.3.107 LINKPERM - ASSIGN CELL PERMEABILITIES TO CELL FACES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LINKPERM keyword assigns the grid cell permeabilities entered via the PERMX, PERMY and PERMZ keywords to a cell face (I±, J±, or K±) and results in the simulator using these values directly in the calculating the transmissibility between grid blocks. This is different to the conventional way of entering permeability data that consists of entering the cell centered permeability and the simulator calculating a weighted average transmissibility based on the cell centered permeability of the up-stream and down-stream grid blocks.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.108 LTOSIGMA - DUAL POROSITY VISCOUS DISPLACEMENT SIGMA PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LTOSIGMA keyword defines parameters to calculate the sigma factor in conjunction with the data entered via the LX, LY and LZ keywords in the GRID section, for when the VISCD keyword has been used in the RUNSPEC section to activate the Dual Porosity Viscous Displacement option. In addition, either the DUALPORO or DUALPERM keyword should be entered in the RUNSPEC section to activate the dual porosity or dual permeability models.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.109 LX - DUAL POROSITY VISCOUS DISPLACEMENT X DIRECTION MATRIX SIZE FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LX keyword defines the size of "representative" matrix grid blocks in the X direction via an array in dual porosity and dual permeability runs, for when the VISCD keyword has been used in the RUNSPEC section to activate the dual porosity viscous displacement option. In addition, either the DUALPORO or DUALPERM keyword should be entered in the RUNSPEC section to activate the dual porosity or dual permeability models. The VISCD option is used to model the viscous displacement of fluids from the matrix by the fracture pressure gradient, for when the fracture system has a more moderate permeability, and flow to and from the matrix caused by the fracture pressure gradient acts as an additional production mechanism.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	LX	LX is an array of real numbers describing the "representative" cell size in the X direction for each cell in the model. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	0

Notes:

1) The number of entries should correspond to the NX x NY x (NZ/2) parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.56: LX Keyword Description

If the VISCD keyword has been used to activate the Dual Porosity Viscous Displacement option and LX has not been specified then LX is set to zero in the calculation of the viscous displacement term. See also the LY, LZ and LTOSIGMA keywords in the GRID section.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--       DEFINE DUAL POROSITY VISCOUS DISPLACEMENT X DIRECTION MATRIX SIZE
--
LX
         6*10.0                                           /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a subset of the grid and the size of the "representative" matrix cells in the X direction to 10.0 ft.; after which the ENDBOX keyword resets the input to be the full grid.

6.3.110 LXFIN – DEFINE LOGARITHMIC LGR GRID BLOCK SPACING IN THE X-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LXFIN keyword defines the parameters for automatically generating a Local Grid Refinement ("LGR") grid in the X direction based on logarithmic block spacing, for when the LGR option has been activated by the LGR keyword in the RUNSPEC section. LXFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.111 LY - DUAL POROSITY VISCOUS DISPLACEMENT Y DIRECTION MATRIX SIZE FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LY keyword defines the size of "representative" matrix grid blocks in the Y direction via an array in dual porosity and dual permeability runs, for when the VISCD keyword has been used in the RUNSPEC section to activate the dual porosity viscous displacement option. In addition, either the DUALPORO or DUALPERM keyword should be entered in the RUNSPEC section to activate the dual porosity or dual permeability models. The VISCD option is used to model the viscous displacement of fluids from the matrix by the fracture pressure gradient, for when the fracture system has a more moderate permeability, and flow to and from the matrix caused by the fracture pressure gradient acts as an additional production mechanism.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	LY	LY is an array of real numbers describing the "representative" cell size in the Y direction for each cell in the model. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	0

Notes:

1) The number of entries should correspond to the NX x NY x (NZ/2) parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.57: LY Keyword Description

If the VISCD keyword has been used to activate the Dual Porosity Viscous Displacement option and LY has not been specified then LY is set to zero in the calculation of the viscous displacement term.

See also the LX, LZ and LTOSIGMA keywords in the GRID section.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--       DEFINE DUAL POROSITY VISCOUS DISPLACEMENT Y DIRECTION MATRIX SIZE
--
LY
         6*15.0                                           /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a subset of the grid and the size of the "representative" matrix cells in the Y direction to 15.0 ft.; after which the ENDBOX keyword resets the input to be the full grid.

6.3.112 LYFIN – DEFINE LOGARITHMIC LGR GRID BLOCK SPACING IN THE Y-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LYFIN keyword defines the parameters for automatically generating a Local Grid Refinement ("LGR") grid in the Y direction based on logarithmic block spacing, for when the LGR option has been activated by the LGR keyword in the RUNSPEC section. LYFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.113 LZ - DUAL POROSITY VISCOUS DISPLACEMENT Z DIRECTION MATRIX SIZE FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LZ keyword defines the size of "representative" matrix grid blocks in the Z direction via an array in dual porosity and dual permeability runs, for when the VISCD keyword has been used in the RUNSPEC section to activate the dual porosity viscous displacement option. In addition, either the DUALPORO or DUALPERM keyword should be entered in the RUNSPEC section to activate the dual porosity or dual permeability models. The VISCD option is used to model the viscous displacement of fluids from the matrix by the fracture pressure gradient, for when the fracture system has a more moderate permeability, and flow to and from the matrix caused by the fracture pressure gradient acts as an additional production mechanism.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	LZ	LZ is an array of real numbers describing the "representative" cell size in the Z direction for each cell in the model. Repeat counts may be used, for example 10*100.0.			
		feet	m	cm	0

Notes:

1) The number of entries should correspond to the NX x NY x (NZ/2) parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.58: LZ Keyword Description

If the VISCD keyword has been used to activate the Dual Porosity Viscous Displacement option and LZ has not been specified then LZ is set to zero in the calculation of the viscous displacement term.

See also the LX, LY and LTOSIGMA keywords in the GRID section.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--       DEFINE DUAL POROSITY VISCOUS DISPLACEMENT Z DIRECTION MATRIX SIZE
--
LZ
         6*3.0                                            /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The example defines a subset of the grid and the size of the "representative" matrix cells in the Y direction to 15.0 ft.; after which the ENDBOX keyword resets the input to be the full grid.

6.3.114 LZFIN – DEFINE LOGARITHMIC LGR GRID BLOCK SPACING IN THE Z-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LZFIN keyword defines the parameters for automatically generating a Local Grid Refinement ("LGR") grid in the Z direction based on logarithmic block spacing, for when the LGR option has been activated by the LGR keyword in the RUNSPEC section. LZFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.115 MAPAXES - DEFINE THE MAP ORIGIN INPUT DATA

Description

MAPAXES specifies the origin of the map used to create the grid. It is usually output by pre-processing software when exporting the grid geometry. The data is not used by OPM Flow intrinsically, but is merely written to the output EGRID file, as specified by the GRIDFILE keyword, for the use of post-processing software like OPM ResInsight.

No.	Name	Description			Default
		Field (feet)	Metric (metres)	Laboratory (metres)	
1	X1	X1 is a real number that defines the x co-ordinate of a point on the y-axis.			None
2	Y1	Y1 is a real number that defines the y co-ordinate of a point on the y-axis.			None
3	X2	X2 is a real number that defines the x co-ordinate of the origin.			None
4	Y2	Y2 is a real number that defines the y co-ordinate of the origin.			None
5	X3	X3 is a real number that defines the x co-ordinate of a point on the x-axis.			None
6	Y3	Y3 is a real number that defines the y co-ordinate of a point on the x-axis.			None
Notes: 1) The keyword is terminated by a "/".					

Table 6.59: MAPAXES Keyword Description

Example

```
--
--          ---------------- MAPAXES -----------------
--          X1       Y1       X2       Y2       X3       Y3
MAPAXES
            0.0      100.0    0.0      0.0      100.0    0.0    /
```

The above example defines the map axes to be exported to the grid file for use by post-processing software.

6.3.116 MAPUNITS – DEFINE THE MAP AXES UNITS

Description

The MAPUNITS keyword defines the units of the coordinates stated on the MAPAXES keyword. It is usually output by pre-processing software when exporting the grid geometry. The data is not used by OPM Flow intrinsically, but is merely written to the output EGRID file, as specified by the GRIDFILE keyword, for the use of post-processing software like OPM ResInsight.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description	Default
1	MAPUNITS	A character string that defines the units of the coordinates stated on the MAPAXES keyword, and should be set to: 1) FEET for field units 2) METRES for metric units, or 3) CM for laboratory units	METRES
Notes: 1) Note the alternative spelling of METRES, that is METERS is not recognized. 2) The keyword is terminated by a "/".			

Table 6.60: MAPUNITS Keyword Description

Example

```
--
--       SET THE MAP UNITS FOR THE MAPAXES KEYWORD
MAPUNITS
         METRES                                                    /
```

The above example specifies the units on the MAPAXES to be the default METRES.

6.3.117 MAXVALUE – SETS A MAXIMUM VALUE FOR AN ARRAY ELEMENT

Description

The MAXVALUE keyword sets a maximum value for the specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the MAXVALUE keyword is being used.

No.	Name	Description	Default
1	ARRAY	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	CONSTANT	CONSTANT is a positive integer or positive real value that an ARRAY element will be reset to if an element in the defined input BOX, as defined by items (3) to (8), is greater than CONSTANT. CONSTANT has in the same units as the ARRAY property.	None
3	I1	The lower bound of the array in the I-direction to be modified must be greater than or equal to one and less than or equal to I2 and NX.	1
4	I2	The upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
5	J1	The lower bound of the array in the J-direction to be modified must be greater than or equal to one and less than or equal to J2 and NY.	1
6	J2	The upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
7	K1	The lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
8	K2	The upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.61: MAXVALUE Keyword Description

The applicable arrays for each section are defined in Table 6.62 on the following page.

MAXVALUE Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL				
DY	PORV	SWCR				
DZ	TRANX	SWU				
PERMX	TRANY	SGL				
PERMY	TRANZ	SGCR				
PERMZ	DIFFX	SGU				
MULTX	DIFFY	KRW				
MULTY	DIFFZ	KRO				
MULTZ	TRANR	KRG				
DR	TRANTHT	PCG				
THETA	DIFFR	PCW				
PERMR	DIFFTHT					
PERMTHT						
DZNET						
PORO						
NTG						
FLUXNUM						
MULTNUM						
MPANUM						
DIFFX						
DIFFY						
DIFFZ						
DIFFR						
DIFFTHT						

Table 6.62: MAXVALUE Keyword Applicable Arrays by Section

Example

```
--
--        ARRAY      CONSTANT        ---------- BOX ---------
--                                   I1  I2    J1  J2    K1  K2
MAXVALUE
          PERMX      1.0E2           1*  1*    1*  1*    1*  1* / MAX VALUE FOR PERMX
          PERMY      1.0E2           1*  1*    1*  1*    1*  1* / MAX VALUE FOR PERMY
          PERMZ      1.0E1           1*  1*    1*  1*    1*  1* / MAX VALUE FOR PERMZ
/
```

The above example resets the maximum values for the PERMX, PERMY and PERMZ, arrays to 100.0, 100.0 and 10.0, respectively, for all cells.

6.3.118 MESSAGE – OUTPUT USER MESSAGE

The MESSAGE keyword outputs a user message to the terminal, as well as to the print (*.PRT) and debug (*.DBG) files. Note this is different to the MESSAGES keyword, that defines OPM Flows message print limits and stop limits generated by the simulator.

See *MESSAGE – Output User Message* in the GLOBAL section for a full description.

6.3.119 MESSAGES – DEFINE MESSAGE PRINT LIMITS AND STOP LIMITS

The MESSAGES keyword defines the print and stops levels for various messages. The "print limits" set the maximum number of messages that will be printed, after which no more messages will be printed and the "stop limits" terminate the run when these limits are exceeded. There are six levels of message that increase in severity from informative all the way to programming errors, as outlined in Error: Reference source not found.

See *MESSAGES – Define Message Print Limits and Stop Limits* in the GLOBAL section for a full description.

6.3.120 MINNNCT – SET A MINIMUM NON-NEIGHBOR CONNECTION TRANSMISSIBILITY

Description

The MINNNCT keyword defines a minimum non-neighbor connection transmissibility below which the non-neighbor connection is deleted. The keyword allows for three minimum values, one for the transmissibility, one for the diffusivity and one for the thermal transmissibility. If the keyword is absent from the input deck then no minimum cut-off is applied.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.121 MINPORV – SET A MINIMUM GRID BLOCK PORE VOLUME THRESHOLD FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MINPORV defines a minimum threshold pore volume that makes all grid blocks whose pore volume is below this value inactive in the model (inactive cells are not used in OPM Flow calculations). Note this keyword is different to the MINPVV keyword in the GRID section, that sets a minimum threshold pore volume for individual cells in the model.

This keyword is an alias for the MINPV keyword in the GRID section, and thus provides the same functionality.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	MINPORV	MINPORV is a real positive number that defines the minimum pore volume for a cell to be active in the model.			
		rb 1.0e-6	rm^3 1.0e-6	rcc 1.0e-6	Defined
Notes: 1) The keyword is terminated by a "/".					

Table 6.63: MINPORV Keyword Description

The MINPORV, MINPV, and MINPVV keywords only apply their minimum threshold pore volume values to active cells. Thus, cells that have been made inactive via setting their ACTNUM values to zero, remain inactive, even if their pore volume exceeds the values set by the MINPORV, MINPV, and MINPVV keywords.

Secondly, although the MINPORV keyword allows one to set a minimum threshold pore volume below the default value, this is not recommended, as cells with small pore volumes can cause significant numerical convergence errors. Thus, in practice, values greater than the default values are normally applied to eliminate cells that have relatively small pore volumes. In addition, the simulator reports the total pore volume and the number of cells made inactive, as well as the pore volume reduction, when the keyword is invoked; allowing one to run some sensitivities to the minimum pore volume value.

See also the PINCH keyword for the treatment of inactive grid cells and pinch-outs.

Example

```
--
--       MINIMUM PORE VOLUME FOR ACTIVE CELLS
--
MINPORV
         500.0                                                    /
```

The above example defines 500 rb (or m3) as the minimum pore volume for a cell to be active in the model.

6.3.122 MINPV – SET A MINIMUM GRID BLOCK PORE VOLUME THRESHOLD FOR ALL CELLS

Description

MINPV defines a minimum threshold pore volume that makes all grid blocks whose pore volume is below this value inactive in the model (inactive cells are not used in OPM Flow calculations). Note this keyword is different to the MINPVV keyword in the GRID section, that sets a minimum threshold pore volume for individual cells in the model.

Note that the MINPORV keyword is an alias for the MINPV keyword in the GRID section, and thus provides the same functionality.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	MINPV	MINPV is a real positive number that defines the minimum pore volume for a cell to be active in the model.			
		rb 1.0e-6	rm^3 1.0e-6	rcc 1.0e-6	Defined
Notes: 1) The keyword is terminated by a "/".					

Table 6.64: MINPV Keyword Description

The MINPV, MINPORV, and MINPVV keywords only apply their minimum threshold pore volume values to active cells. Thus, cells that have been made inactive via setting their ACTNUM values to zero, remain inactive, even if their pore volume exceeds the values set by the MINPV, MINPORV, and MINPVV keywords.

Secondly, although the MINPV keyword allows one to set a minimum threshold pore volume below the default value, this is not recommended, as cells with small pore volumes can cause significant numerical convergence errors. Thus, in practice, values greater than the default values are normally applied to eliminate cells that have relatively small pore volumes. In addition, the simulator reports the total pore volume and the number of cells made inactive, as well as the pore volume reduction, when the keyword is invoked; allowing one to run some sensitivities to the minimum pore volume value.

See also the PINCH keyword for the treatment of inactive grid cells and pinch-outs.

Example

```
--
--       MINIMUM PORE VOLUME FOR ACTIVE CELLS
--
MINPV
         500.0                                                    /
```

The above example defines 500 rb (or m3) as the minimum pore volume for a cell to be active in the model.

6.3.123 MINPVV – SET A MINIMUM GRID BLOCK PORE VOLUME THRESHOLD FOR INDIVIDUAL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MINPVV is an array that defines the minimum threshold pore volume for each cell, that makes grid blocks whose pore volume is below this value inactive in the model (inactive cells are not used in OPM Flow calculations).

Note this keyword is different to the MINPV and MINPORV keywords in the GRID section, that set a constant minimum threshold pore volume for all cells in the model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	MINPVV	MINPVV is an array of real positive numbers that defines the minimum pore volumes for each cell in the model in order for the cells to be active.			
		rb 1.0e-6	rm^3 1.0e-6	rcc 1.0e-6	Defined

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.65: MINPVV Keyword Description

The MINPVV, MINPV, and MINPORV keywords only apply their minimum threshold pore volume values to active cells. Thus, cells that have been made inactive via setting their ACTNUM values to zero, remain inactive, even if their pore volume exceeds the values set by the MINPVV, MINPV, and MINPORV keywords.

Secondly, although the MINPVV keyword allows one to set a minimum threshold pore volume below the default value, this is not recommended, as cells with small pore volumes can cause significant numerical convergence errors. Thus, in practice, values greater than the default values are normally applied to eliminate cells that have relatively small pore volumes. In addition, the simulator reports the total pore volume and the number of cells made inactive, as well as the pore volume reduction, when the keyword is invoked; allowing one to run some sensitivities to the minimum pore volume value.

See also the PINCH keyword for the treatment of inactive grid cells and pinch-outs.

Example

The example below shows how to define 500 rb (or m3) as the minimum pore volume for all cells in layer 19 to be active in the model, and 750 rb (or m3) as the minimum pore volume for all cells in layer 20, by using the BOX keyword to set the portion of the grid of interest.

```
--
--       DEFINE A BOX GRID FOR THE BOTTOM TWO LAYERS OF A 100 X 100 X 20 MODEL
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   19  20 / SELECT THE BOTTOM LAYERS
--
--       MINIMUM PORE VOLUME FOR INDIVIDUAL CELLS TO BE ACTIVE
--
MINPVV
         10000*500.0   10000*750.0
/
--
--       RESET THE INPUT BOX TO BE THE FULL MODEL
--
ENDBOX
```

Although this will work in the commercial simulators, it does not currently work in OPM Flow, that is one cannot use the MINPVV keyword in conjunction with the BOX keyword, as shown in the aforementioned example.

Instead one can use:

```
--
--       MINIMUM PORE VOLUME FOR INDIVIDUAL CELLS TO BE ACTIVE
--
MINPVV
         10000*        10000*     10000*   10000*   10000*
         10000*        10000*     10000*   10000*   10000*
         10000*        10000*     10000*   10000*   10000*
         10000*        10000*     10000*
         10000*500.0   10000*750.0                                    /
```

To accomplish the same thing, where the 10000* instructs the simulator to use the default value of 1.0 x 10^{-6} for 10,000 cells, which in this case is one layer.

6.3.124 MINVALUE – SET A MINIMUM VALUE FOR AN ARRAY ELEMENT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MINVALUE keyword sets a minimum value for the specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the MINVALUE keyword is being used.

No.	Name	Description	Default
1	ARRAY	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	CONSTANT	CONSTANT is a positive integer or positive real value that an ARRAY element will be reset to if an element in the defined input BOX, as defined by items (3) to (8), is less than CONSTANT. CONSTANT has in the same units as the ARRAY property.	None
3	I1	A positive integer that defines the lower bound of the array in the I-direction to be modified must be greater than or equal to one and less than or equal to I2 and NX.	1
4	I2	A positive integer that defines the upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
5	J1	A positive integer that defines the lower bound of the array in the J-direction to be modified must be greater than or equal to one and less than or equal to J2 and NY.	1
6	J2	A positive integer that defines the upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
7	K1	A positive integer that defines the lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
8	K2	A positive integer that defines the upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.66: MINVALUE Keyword Description

The applicable arrays for each section are defined in Table 6.67 on the following page.

EQUALS Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL				
DY	PORV	SWCR				
DZ	TRANX	SWU				
PERMX	TRANY	SGL				
PERMY	TRANZ	SGCR				
PERMZ	DIFFX	SGU

Table 6.67: MINVALUE Keyword Applicable Arrays by Section

Example

```
--
--        ARRAY     CONSTANT         ---------- BOX ---------
--                                   I1  I2    J1  J2    K1  K2
MINVALUE
          PERMX     1.0E0            1*  1*    1*  1*    1*  1* / MINIMUM PERMX
          PERMY     1.0E0            1*  1*    1*  1*    1*  1* / MINIMUM PERMY
          PERMZ     1.0E-1           1*  1*    1*  1*    1*  1* / MINIMUM PERMZ
/
```

The above example resets the minimum values for the PERMX, PERMY and PERMZ, arrays to 1.0, 1.0 and 0.1, respectively, for all cells.

6.3.125 MPFANUM – DEFINE MULTI-POINT FLUX DISCRETIZATION REGIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MPFANUM keyword defines regions in the model where the multi-point flux discretization should be applied.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.126 MPFNNC – DEFINE MULTI-POINT FLUX NON-NEIGHBOR CONNECTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MPFNNC keyword defines multi-point flux non-neighbor connections explicitly.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.127 MULTFLT – MULTIPLY THE TRANSMISSIBILITY OF A DEFINED FAULT BY A CONSTANT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTFLT enables the transmissibilities across defined faults, as declared by the FAULTS keyword, to be modified. They keyword allows for the re-scaling of the existing fault transmissibilities calculated by OPM Flow, for example setting a fault to be completely sealing by setting the multiplier to zero.

No.	Name	Description	Default
1	FLTNAME	FLTNAME is a character string enclosed in quotes with a maximum length of eight characters, that defines the name of the fault that FLTMULT will be applied to. FLTNAME must have previously been defined using the FAULTS keyword in GRID section	None
2	FLT-TRS	A positive real number that sets the transmissible multiplier to be applied to the FLTNAME transmissibilities positive real number that sets the transmissible multiplier to be applied to the FLTNAME transmissibilities.	1.0
3	FLT-DIF	A positive real number that sets the diffusivity multiplier to be applied to the FLTNAME diffusivities. This option should only be used if the Diffusion option has been made activate by the DIFFUSE keyword in the RUNSPEC section. OPM Flow does not support this Diffusion option.	1.0
Notes: 1) Repeated entries of the same FLTNAME will result in all but the last entry being overwritten. 2) Each record must be terminated by a "/" and the keyword is terminated by a "/".			

Table 6.68: MULTFLT Keyword Description

Example

```
--
--        MODIFY THE TRANSMISSIBILITES ACROSS DEFINED FAULTS
--
--        FAULT             TRANS           DIFUSS
--        NAME              MULTIPLIER      MULTIPLIER
MULTFLT
          'FAULT01'         0.0                                 / FAULT MULTIPLIERS
          'FAULT02'         0.0                                 / FAULT MULTIPLIERS
          'FAULT03'         0.0                                 / FAULT MULTIPLIERS
/
```

The above example sets the fault transmissibility multiplier for defined faults named FAULT01, FAULT02, and FAULT03 to zero making the faults sealing in the model.

6.3.128 MULTIPLY – MULTIPLY A SPECIFIED ARRAY BY A CONSTANT

Description

The MULTIPLY keyword multiplies a specified array or part of an array by a constant. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

No.	Name	Description	Default
1	ARRAY	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	CONSTANT	An integer or real value to multiply the ARRAY by in the same units as the ARRAY property.	None
3	I1	A positive integer that defines the lower bound of the array in the I-direction to be modified must be greater than or equal to one and less than or equal to I2 and NX.	1
4	I2	A positive integer that defines the upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
5	J1	A positive integer that defines the lower bound of the array in the J-direction to be modified must be greater than or equal to one and less than or equal to J2 and NY.	1
6	J2	A positive integer that defines the upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
7	K1	A positive integer that defines the lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
8	K2	A positive integer that defines the upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.

2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.69: MULTIPLY Keyword Description

The applicable arrays for each section are defined in Table 6.70 as shown on the next page.

MULTIPLY Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL	ENDNUM	PRESSURE		
DY	PORV	SWCR	EQLNUM	SWAT

Table 6.70: MULTIPLY Keyword Applicable Arrays by Section

Example

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
MULTIPLY
          PERMZ       0.50000       1*  1*   1*  1*   1*  1* / PERMZ * 0.5
/
```

The above example multiples the PERMZ property array by 0.5 throughout the model.

6.3.129 MULTIREG – MULTIPLY AN ARRAY BY A CONSTANT BASED ON A REGION NUMBER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MULTIREG keyword multiplies an array or part of an array by a constant for cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTIREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the MULTIREG keyword is being used.

No.	Name	Description	Default
1	ARRAY	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and enclosed in quotes.	None
2	CONSTANT	An integer or real value to multiply the ARRAY by in the same units as the ARRAY property for a given REGION.	0
3	REGION	REGION is a positive integer representing the region for which the CONSTANT in (2) should be applied	None
4	ARRAY	The ARRAY to use for applying the CONSTANT in (2) based on the REGION in (3). ARRAY can have the following values: 1) F for the FLUXNUM array 2) M for the MULTNUM array 3) O for the OPERNUM array	M
Notes: 1) Where the REGION should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section. 2) Each record must be terminated by a "/" and the keyword is terminated by a "/".			

Table 6.71: MULTIREG Keyword Description

The applicable arrays for each section are defined in Table 6.72.

MULTREG Keyword And Variable Options By Section

Table 6.72: MULTIREG Keyword Applicable Arrays by Section

Example

```
--
-- FIRST DEFINE THE PROPERTY ARRAYS AND MULTNUM ARRAYS FOR 10 X 10 X 20 MODEL
--
--  ARRAY     CONSTANT      ---------- BOX ---------
--                           I1  I2   J1  J2   K1  K2
EQUALS
    PORO       0.2000       1*  1*   1*  1*   1*  1*  / PORO  TO 0.20 IN MODEL
    PERMX      100.00       1*  1*   1*  1*   1*  1*  / PERMX TO 0.10 IN MODEL
    MULTNUM    1            1*  1*   1*  1*   1*  1*  / MULTNUM IN MODEL
    MULTNUM    2            1*  5    1   5    6   6   / MULTNUM IN MODEL
    MULTNUM    3            1*  1*   1*  1*   10  10  / MULTNUM IN MODEL
/
--
-- NOW RESET PORO AND PERMX BASED ON THE MULTNUM REGION NUMBER
--
-- MULTIPLY AN ARRAY BY A CONSTANT BASED ON A REGION NUMBER
--
--    ARRAY     CONSTANT  REGION   REGION ARRAY
--              VALUE     NUMBER    M / F / O
MULTIREG
      PORO      1.050     1         M               /
      PORO      1.100     2         M               /
      PORO      0.950     3         M               /
      PERMX      1.25     1         M               /
      PERMX      1.30     2         M               /
      PERMX      0.90     3         M               /
/
```

The example first defines the PORO and PERMX property arrays for the model and then sets the MULTNUM array to 1 for all cells in the model, after which selected areas of model are assigned various MULTNUM integer values. The MULTIREG can then be invoked to multiple the PORO and PERMX arrays by a constant for the various MULTNUM regions.

6.3.130 MULTNUM – DEFINE THE MULTIPLE TRANSMISSIBILITY REGIONS

Description

The MULTNUM keyword defines the inter-region transmissibility region numbers for each grid block, as such there must be one entry for each cell in the model. The array can be used with the EQUALREG, ADDREG, COPYREG, MULTIREG, MULTREGP and MULTREGT keywords in calculating various grid properties in the GRID section.

No.	Name	Description	Default
1	MULTNUM	MULTNUM defines an array of positive integers assigning a grid cell to a particular inter-region transmissibility region. The maximum number of MULTNUM regions is set by the NRMULT variable on the GRIDOPTS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.73: MULTNUM Keyword Description

Examples

The example below sets three MULTNUM regions for a 4 x 5 x 2 model.

```
--
--        DEFINE MULTNUM REGIONS FOR ALL CELLS
--
MULTNUM
          2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
          3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--        ARRAY        CONSTANT      ---------- BOX ---------
--                                    I1  I2    J1  J2    K1  K2
EQUALS
          MULTNUM      1             1*  1*    1*  1*    1*  1* / SET REGION 1
          MULTNUM      2             1   2     1   2     1   1  / SET REGION 2
          MULTNUM      3             1   2     1   2     2   2  / SET REGION 3
/
```

One can then increase PERMX by 25% in region three only.

```
--
--        MULTIPLY AN ARRAY BY A CONSTANT BASED ON A REGION NUMBER
--
--        ARRAY      CONSTANT  REGION   REGION ARRAY
--                   VALUE     NUMBER    M / F / O
MULTIREG
          PERMX      1.25      3         M                    /
/
```

6.3.131 MULTPV – MULTIPLY CELL PORE VOLUMES BY A CONSTANT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTPV multiples the pore volumes of a cell by a real positive constant for all the cells in the model via an array. An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTPV keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description	Default
1	MULTPV	MULTPV is an array of real positive numbers assigning the pore volume multipliers for each cell in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.74: MULTPV Keyword Description

See also the MULTREGP keyword for scaling the cell pore volumes by region numbers.

Example

```
--
--        DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--        ---------- BOX ---------
--        I1  I2   J1  J2   K1  K2
BOX
          10  10   1   6    1   3                          / DEFINE BOX AREA
--
--        SET MULTX+ TRANSMISSIBILITY MULTIPLIERS
--
MULTPV
          18*0.0500                                       /
--
--        DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.05 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.132 MULTR - MULTIPLY CELL TRANSMISSIBILITY IN THE +R DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTR multiples the transmissibility between two cell faces in the +R direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I+1, J, K). An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTR keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword should only be used with radial and spider grids, as declared by the RADIAL or SPIDER keywords in the RUNSPEC section.

No.	Name	Description	Default
1	MULTR+	MULTR+ is an array of real positive numbers assigning the transmissibility multipliers in the +R direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.75: MULTR Keyword Description

See also the MULTR-, MULTTHT, MULTTHT-, MULTZ and MULTZ- keywords for scaling transmissible between between grid cells in the R direction.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   3                          / DEFINE BOX AREA
--
--       SET MULTR+ TRANSMISSIBILITY MULTIPLIERS
--
MULTR
         18*0.300                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.3 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.133 MULTR- - MULTIPLY CELL TRANSMISSIBILITY IN THE -R DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTR- multiples the transmissibility between two cell faces in the -R direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I-1, J, K) and (I, J, K). An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTR- keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword should only be used with radial and spider grids, as declared by the RADIAL or SPIDER keywords in the RUNSPEC section.

No.	Name	Description	Default
1	MULTR-	MULTR- is an array of real positive numbers assigning the transmissibility multipliers in the -R direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.76: MULTR- Keyword Description

Note that OPM Flow does not require the GRIDOPTS(TRANMULT) parameter in the RUNSPEC section to be set to YES, in order to use this and other negative directional dependent multiplier keywords in the input deck. Whereas, the commercial simulator will terminate with an error if the keyword is present, and the GRIDOPTS(TRANMULT) parameter has not been set to YES.

See also the MULTR, MULTTHT, MULTTHT-, MULTZ and MULTZ- keywords for scaling transmissible between cells in the R direction.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--       SET MULTX TRANSMISSIBILITY MULTIPLIERS CELLS
--
MULTR-
         6*0.500                                         /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.5 scaling multiplier for the six cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.134 MULTREGD – MULTIPLY DIFFUSIVITIES BETWEEN REGIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MULTREGT keyword multiplies the diffusivity between two regions by a constant. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGT keyword is read by the simulator. The constant should be a real number.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	REGION1	A positive integer value that defines the from REGION number for which the CONSTANT in (2) should be applied.	None
2	REGION2	A positive integer value that defines the to REGION number for which the CONSTANT in (2) should be applied.	None
3	CONSTANT	A real value to multiply the diffusivity between REGION1 and REGION2.	1
4	DIR	A character string that defines the direction to apply the diffusivity multiplier between the two regions, should be set to one of the following X, Y, Z, XY, YX, XZ, or XYZ.	XYZ
5	TYPE	A character string that defines the type of connections the diffusivity multiplier should be applied to, should be one of the following: 1) NNC – Only apply the diffusivity multiplier between REGION1 and REGION2 to non-neighbor connections. 2) NONNC – Do not apply the diffusivity multiplier between REGION1 and REGION2 to non-neighbor connections. 3) ALL - Apply the diffusivity multiplier between REGION1 and REGION2 to all connections.	ALL
6	ARRAY	The ARRAY to use for applying the CONSTANT in (2) based on the ARRAY in (1). ARRAY can have the following values: 1) F for the FLUXNUM array 2) M for the MULTNUM array 3) O for the OPERNUM array	M

Notes:

1) Where REGION1 and REGION2 should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.77: MULTREGD Keyword Description

Example

```
--
--    MULTIPLY DIFFUSIVITIES BETWEEN RESERVOIRS
--
--    REGION   REGION   DIFFS   DIREC   NNC    REGION ARRAY
--    FROM     TO       MULT    OPT     OPTS   M / F / O
MULTREGD
      1*       1*       1.05    1*     'ALL'   M           / ALL REGIONS
/
```

The above example multiplies the thermal conductivities between all the MULTNUM regions by 1.05 in all directions and for all connections types.

6.3.135 MULTREGH – MULTIPLY THERMAL CONDUCTIVITIES BETWEEN REGIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MULTREGH keyword multiplies the thermal conductivity between two regions by a constant. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGT keyword is read by the simulator. The constant should be a real number.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	REGION1	A positive integer value that defines the from REGION number for which the CONSTANT in (2) should be applied.	None
2	REGION2	A positive integer value that defines the to REGION number for which the CONSTANT in (2) should be applied.	None
3	CONSTANT	A real value to multiply the thermal conductivity between REGION1 and REGION2.	1
4	DIR	A character string that defines the direction to apply the thermal conductivity multiplier between the two regions, should be set to one of the following X, Y, Z, XY, YX, XZ, or XYZ.	XYZ
5	TYPE	A character string that defines the type of connections the thermal conductivity multiplier should be applied to, should be one of the following: 1) NNC – Only apply the thermal conductivity multiplier between REGION1 and REGION2 to non-neighbor connections. 2) NONNC – Do not apply the thermal conductivity multiplier between REGION1 and REGION2 to non-neighbor connections. 3) ALL - Apply the thermal conductivity multiplier between REGION1 and REGION2 to all connections.	ALL
6	ARRAY	The ARRAY to use for applying the CONSTANT in (2) based on the ARRAY in (1). ARRAY can have the following values: 1) F for the FLUXNUM array. 2) M for the MULTNUM array. 3) O for the OPERNUM array.	M

Notes:

1) Where REGION1 and REGION2 should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.78: MULTREGH Keyword Description

Example

```
--
--    MULTIPLY THERMAL CONDUCTIVITIES BETWEEN RESERVOIRS
--
--    REGION   REGION   CONDS   DIREC   NNC    REGION ARRAY
--    FROM     TO       MULT    OPT     OPTS   M / F / O
MULTREGH
      1*       1*       1.05    1*     'ALL'   M           / ALL REGIONS
/
```

The above example multiplies the diffusivities between all the MULTNUM regions by 1.05 in all directions and for all connections types.

6.3.136 MULTREGP – MULTIPLY PORE VOLUMES BASED ON REGION NUMBER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MULTREGP keyword multiplies the pore volume of a cell by a constant for all cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGP keyword is read by the simulator. The constant should be a real number.

No.	Name	Description	Default
1	REGION	REGION is a positive integer representing the region for which the CONSTANT in (2) should be applied.	None
2	CONSTANT	A real value to multiply the pore volume by for a given REGION.	1
3	ARRAY	The ARRAY to use for applying the CONSTANT in (2) based on the REGION in (1). ARRAY can have the following values: 1) F for the FLUXNUM array. 2) M for the MULTNUM array. 3) O for the OPERNUM array.	M

Notes:

1) Where the REGION should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.79: MULTREGP Keyword Description

Example

```
--
-- RESET PORE VOLUME FOR DIFFERENT REGIONS
--
--    REGION    PORV          REGION ARRAY
--    NUMBER    MULT          M / F / O
MULTREGP
         1       1.0456573    M             /  Fault Block 1
         2       0            M             /  Fault Block 2
         3       0.9756715    M             /  Fault Block 3
         4       0            M             /  Inactive Blocks
/
```

The above example re-scales the pore volumes for MULTNUM regions one and three and makes regions two and four inactive by setting their pore volumes to zero.

6.3.137 MULTREGT – MULTIPLY TRANSMISSIBILITIES BETWEEN REGIONS

Description

The MULTREGT keyword multiplies the transmissibility between two regions by a constant. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGT keyword is read by the simulator. The constant should be a real number.

No.	Name	Description	Default
1	REGION1	A positive integer value that defines the from REGION number for which the CONSTANT in (2) should be applied.	None
2	REGION2	A positive integer value that defines the to REGION number for which the CONSTANT in (2) should be applied.	None
3	CONSTANT	A real positive value to multiply the transmissibility between REGION1 and REGION2.	1
4	DIR	A character string that defines the direction to apply the transmissibility multiplier between the two regions, should be set to one of the following X, Y, Z, XY, YX, XZ, or XYZ.	XYZ
5	TYPE	A character string that defines the type of connections the transmissibility multiplier should be applied to, should be one of the following: 1) NNC – Only apply the transmissibility multiplier between REGION1 and REGION2 to non-neighbor connections. 2) NONNC – Do not apply the transmissibility multiplier between REGION1 and REGION2 to non-neighbor connections. 3) ALL - Apply the transmissibility multiplier between REGION1 and REGION2 to all connections.	ALL
6	ARRAY	The ARRAY to use for applying the CONSTANT in (2) based on the ARRAY in (1). ARRAY can have the following values: 1) F for the FLUXNUM array 2) M for the MULTNUM array 3) O for the OPERNUM array	M

Notes:

1) Where REGION1 and REGION2 should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.80: MULTREGT Keyword Description

Note

Note if the MULTREGT keyword is used in the EDIT section, OPM Flow will always apply the changes irrespective, of if the TRANX, TRANY and TRANZ transmissibility arrays have been entered or not in the EDIT section.

This behavior is different to the commercial simulator that only applies the keyword if the transmissibility arrays have been entered in the EDIT section.

Example

```
--
--    SET TRANSMISSIBILITES ACROSS DIFFERENT RESERVOIRS TO ZERO
--
--    REGION   REGION   TRANS   DIREC   NNC    REGION ARRAY
--    FROM     TO       MULT    OPT     OPTS   M / F / O
MULTREGT
      1*       1*       0.0     1*     'ALL'   M           / ALL REGIONS SEALED
/
```

The above example isolates all regions from one another by setting the transmissibility for the MULTNUM regions to zero in all directions and for all connections types.

6.3.138 MULTTHT - MULTIPLY CELL TRANSMISSIBILITY IN THE +THETA DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTTHT multiples the transmissibility between two cell faces in the +Theta direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I, J+1, K). An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTTHT keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword should only be used with radial and spider grids, as declared by the RADIAL or SPIDER keywords in the RUNSPEC section.

No.	Name	Description	Default
1	MULTTHT+	MULTTHT+ is an array of real positive numbers assigning the transmissibility multipliers in the +Theta direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.81: MULTTHT Keyword Description

See also the MULTTHT-, MULTR, MULTR-, MULTZ and MULTZ- keywords for scaling transmissible between I grid cells in the Theta direction.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   3                          / DEFINE BOX AREA
--
--       SET MULTTHT+ TRANSMISSIBILITY MULTIPLIERS
--
MULTTHT
         18*0.300                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.3 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.139 MULTTHT- - MULTIPLY CELL TRANSMISSIBILITY IN THE -THETA DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTTHT- multiples the transmissibility between two cell faces in the -Theta direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J-1, K) and (I, J, K). An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTTHT- keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword should only be used with radial and spider grids, as declared by the RADIAL or SPIDER keywords in the RUNSPEC section.

No.	Name	Description	Default
1	MULTTHT-	MULTTHT- is an array of real positive numbers assigning the transmissibility multipliers in the -Theta direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.82: MULTTHT- Keyword Description

Note that OPM Flow does not require the GRIDOPTS(TRANMULT) parameter in the RUNSPEC section to be set to YES, in order to use this and other negative directional dependent multiplier keywords in the input deck. Whereas, the commercial simulator will terminate with an error if the keyword is present, and the GRIDOPTS(TRANMULT) parameter has not been set to YES.

See also the MULTTHT, MULTR, MULTR-, MULTZ and MULTZ- keywords for scaling transmissible between I grid cells in the Theta direction.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--       SET MULTX TRANSMISSIBILITY MULTIPLIERS CELLS
--
MULTTHT-
         6*0.500                                         /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.5 scaling multiplier for the six cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.140 MULTX - MULTIPLY CELL TRANSMISSIBILITY IN THE +X DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTX multiples the transmissibility between two cell faces in the +X direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I+I, J, K).

An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTX keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description	Default
1	MULTX+	MULTX+ is an array of real positive numbers assigning the transmissibility multipliers in the +X direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.83: MULTX Keyword Description

See also the MULTX-, MULTY, MULTY-, MULTZ and MULTZ- keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   3                          / DEFINE BOX AREA
--
--       SET MULTX+ TRANSMISSIBILITY MULTIPLIERS
--
MULTX
         18*0.300                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.3 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.141 MULTX- - MULTIPLY CELL TRANSMISSIBILITY IN THE -X DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTX- multiples the transmissibility between two cell faces in the -X direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I-1, J, K) and (I, J, K). An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTX- keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description	Default
1	MULTX-	MULTX- is an array of real positive numbers assigning the transmissibility multipliers in the -X direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.84: MULTX- Keyword Description

Note that OPM Flow does not require the GRIDOPTS(TRANMULT) parameter in the RUNSPEC section to be set to YES, in order to use this and other negative directional dependent multiplier keywords in the input deck. Whereas, the commercial simulator will terminate with an error if the keyword is present, and the GRIDOPTS(TRANMULT) parameter has not been set to YES.

See also the MULTX, MULTY, MULTY-, MULTZ and MULTZ- keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--       SET MULTX TRANSMISSIBILITY MULTIPLIERS CELLS
--
MULTX-
         6*0.500                                         /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.5 scaling multiplier for the six cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.142 MULTY - MULTIPLY CELL TRANSMISSIBILITY IN THE +Y DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTY multiples the transmissibility between two cell faces in the +Y direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I, J+1, K).

An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTY keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description	Default
1	MULTY+	MULTY+ is an array of real positive numbers assigning the transmissibility multipliers in the +Y direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.85: MULTY Keyword Description

See also the MULTY-, MULTX, MULTX-, MULTZ and MULTZ- keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   3                          / DEFINE BOX AREA
--
--       SET MULTX+ TRANSMISSIBILITY MULTIPLIERS
--
MULTY
         18*0.300                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.3 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.143 MULTY- - MULTIPLY CELL TRANSMISSIBILITY IN THE -Y DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTY- multiples the transmissibility between two cell faces in the -Y direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J-1, K) and (I, J, K). An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTY- keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description	Default
1	MULTY-	MULTY- is an array of real positive numbers assigning the transmissibility multipliers in the -Y direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.86: MULTY- Keyword Description

Note that OPM Flow does not require the GRIDOPTS(TRANMULT) parameter in the RUNSPEC section to be set to YES, in order to use this and other negative directional dependent multiplier keywords in the input deck. Whereas, the commercial simulator will terminate with an error if the keyword is present, and the GRIDOPTS(TRANMULT) parameter has not been set to YES.

See also the MULTY, MULTX, MULTX-, MULTZ and MULTZ- keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--       SET MULTX TRANSMISSIBILITY MULTIPLIERS CELLS
--
MULTY-
         6*0.500                                         /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.5 scaling multiplier for the six cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.144 MULTZ - MULTIPLY CELL TRANSMISSIBILITY IN THE +Z DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTZ multiples the transmissibility between two cell faces in the +Z direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I, J, K+1).

An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTZ keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description	Default
1	MULTZ+	MULTZ+ is an array of real positive numbers assigning the transmissibility multipliers in the +Z direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.87: MULTZ Keyword Description

See also the MULTZ-, MULTX, MULTX-, MULTY and MULTY- keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   18   1   1                          / DEFINE BOX AREA
--
--       SET MULTX+ TRANSMISSIBILITY MULTIPLIERS
--
MULTZ
         18*0.300                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.3 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.145 MULTZ- - MULTIPLY CELL TRANSMISSIBILITY IN THE -Z DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

MULTZ- multiples the transmissibility between two cell faces in the -Z direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K-1) and (I, J, K). An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTZ- keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description	Default
1	MULTZ-	MULTZ- is an array of real positive numbers assigning the transmissibility multipliers in the -X direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.88: MULTZ- Keyword Description

Note that OPM Flow does not require the GRIDOPTS(TRANMULT) parameter in the RUNSPEC section to be set to YES, in order to use this and other negative directional dependent multiplier keywords in the input deck. Whereas, the commercial simulator will terminate with an error if the keyword is present, and the GRIDOPTS(TRANMULT) parameter has not been set to YES.

See also the MULTZ, MULTX, MULTX-, MULTY and MULTY- keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   1                          / DEFINE BOX AREA
--
--       SET MULTX TRANSMISSIBILITY MULTIPLIERS CELLS
--
MULTZ-
         6*0.500                                         /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.5 scaling multiplier for the six cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.146 NEWTRAN – ACTIVATE IRREGULAR CORNER-POINT GRID TRANSMISSIBILITIES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword switches on Irregular Corner-Point Grid geometry transmissibility calculation, which is the default option for this type of grid. Grids defined with the COORD and ZCORN keywords will always invoke this option by default.

For Cartesian Regular Grids defined by the DX, DY, and DZ series of keywords the block center geometry transmissibility calculations should be activated via the OLDTRAN keyword. Again this is automatically invoked if this type of grid is being employed.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE IRREGULAR CORNER-POINT GRID TRANSMISSIBILITIES
--
NEWTRAN
```

The above example manually activates Irregular Corner-Point Grid transmissibility calculations.

6.3.147 NINENUM – DEFINE THE NINE-POINT DISCRETIZATION REGION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NINENUM keyword defines areas in the grid that should use the Nine-Point Discretization formulation by setting a grid block's NINENUM value to one, or zero for the conventional standard five-point discretization formulation, for when the Nine-Point Discretization formulation has been activated by the NINEPOIN keyword in the RUNSPEC section. There should be a NINENUM value for each grid block in the model. Note that if the if the NINEPOIN keyword in the RUNSPEC section has been invoked and the NINENUM keyword has not been used in the input deck, then all the grid will use the nine-point scheme.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	NINENUM	NINENUM defines an integer array of zeros and ones assigning a grid cell to a particular discretization region, a value of zero for five-point or a value of one for nine-point discretization. Note that the default value of one implies a cell is included in the Nine-Point Discretization region; thus, if a cell is to use the conventional standard five-point finite difference discretization formulation, then NINENUM must be explicitly set to zero.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.89: NINENUM Keyword Description

The NINENUM keyword cannot be used in models with Local Grid Refinements ("LGR") to set different discretization regions within the model, that is if LGRs are present in the model either all the grid uses nine-point discretization, if NINEPOIN is present in the RUNSPEC section, or five-point if NINEPOIN is absent.

Example

The example below sets a portion of the model to us the Nine-Point Discretization formulation.

```
--
--       DEFINE NINE-POINT DISCRETIZATION REGION FOR ALL CELLS
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         NINENUM'    0            1*  1*   1*  1*   1*  1* / FIVE-POINT
         NINENUM'    1            1*  1*   1*  1*   1   5  / NINE-POINT
/
```

Here the first line sets all the grid to us the five-point discretization formulation, all values set to zero, and then the second line sets all the cells in the layers one to five to use the nine-point discretization formulation.

6.3.148 NMATOPTS – DEFINE THE DISCRETIZED MATRIX DUAL POROSITY PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The NMATOPTS keyword defines the Discretized Matrix Dual Porosity parameters for when the Discretized Matrix Dual Porosity option has been activated by NMATRIX keyword in the RUNSPEC section. The option allows the matrix grid blocks to be subdivided into smaller cells for more accurate flow calculations, in particular the modeling of transient flow within the matrix grid blocks.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.149 NNC – DEFINE NON-NEIGHBOR CONNECTIONS BETWEEN CELLS MANUALLY

Description

NNC enables Non-Neighbor Connections ("NNC") to be manually defined. This keyword is normally generated by static modeling software as opposed to be manually entered in the OPM Flow input deck due to the verbosity and complexity of calculating the required parameters for this keyword.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	I1	A positive integer that defines the first grid block in the I-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NX on the DIMENS keyword in the RUNSPEC section.			None
2	J1	A positive integer that defines the first grid block in the J-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NY on the DIMENS keyword in the RUNSPEC section.			None
3	K1	A positive integer that defines the first grid block in the K-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NZ on the DIMENS keyword in the RUNSPEC section.			None
4	I2	A positive integer that defines the second grid block in the I-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NX on the DIMENS keyword in the RUNSPEC section.			None
5	J2	A positive integer that defines the second grid block in the J-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NY on the DIMENS keyword in the RUNSPEC section.			None
6	K2	A positive integer that defines the second grid block in the K-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NZ on the DIMENS keyword in the RUNSPEC section.			None
7	TRANSNNC	TRANSNNC is a positive real number greater than or equal to zero that defines the transmissibility between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2). The default value of zero sets the transmissibility between the two cells to zero.			
		cP.rb/day/psia	cP.rm^3/day/bars	cP.rcc/hr/atm	0.0
8	ISATNUM1	ISATNUM1 is a positive integer defining which saturation table number (relative permeability table) to be used for flow from the first grid block to the second grid block. The default value of zero means the existing saturation table allocated to the upstream cell (I1,J1,K1).			0

No.	Name	Description			Default
		Field	Metric	Laboratory	
9	ISATNUM2	ISATNUM2 is a positive integer defining which saturation table number (relative permeability table) to be used for flow from the second grid block to the first grid block. The default value of zero means the existing saturation table allocated to the downstream cell (I2,J2,K2).			0
10	IPRSNUM1	IPRSNUM1 is a positive integer defining which pressure table number (PVT table) to be used for flow from the first grid block to the second grid block. The default value of zero means the existing PVT table allocated to the upstream cell (I1,J1,K1).			0
11	IPRSNUM2	IPRSNUM2 is a positive integer defining which pressure table number (PVT table) to be used for flow from the second grid block to the first grid block. The default value of zero means the existing PVT table allocated to the downstream cell (I2,J2,K2).			0
12	FACE1	FACE1 is a character string that defines the face associated with flow from the first grid block to the second grid block, where FACE1 can have values of: X+, X-, Y+, Y-, Z+, or Z-.			None
13	FACE2	FACE2 is a character string that defines the face associated with flow from the second grid block to the first grid block, where FACE2 can have values of: X+, X-, Y+, Y-, Z+, or Z-.			None
14	DIFFNNC	DIFFNNC is a positive real number that defines the diffusivity between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2).			
		feet	meters	cm	0.0
15	DISPNNC	DISPNNC s a positive real number that defines the dispersion coefficient $\frac{1}{(Area\ x\ Porosity)}$ between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2), used with the DISPERSE option.			
		ft^{-2}	m^{-2}	cm^{-2}	0.0
16	AREANNC	AREANNC is a positive real number that defines the area associated with the connection between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2).			
		ft^2	m^2	cm^2	None
17	PERMNNC	AREANNC is a positive real number that defines the permeability associated with the connection between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2). This used by the non-Darcy option.			
		mD	mD	mD	None

Notes:

1) Only functionality defined by items (1) to (7) are activated in OPM Flow.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.90: NNC Keyword Description

Note that although items (8) to (17) for this keyword are not available in OPM Flow, even if they were, it is strongly recommended that these items are defaulted if the data is being entered manually, as opposed to being generated by a pre-processing software.

Care should be taken that cells in different PVTNUM regions (see the PVTNUM keyword in the REGIONS section) are not connected, since the fluid properties are associated with a cell. If for example, a rbbl or a rm3 of oil flows from PVTNUM region 1 to PVTNUM region 2, then the oil properties of that oil will change from the PVT 1 data set to the PVT data set 2. This will result in material balance errors, that may or may not cause numerical issues.

If the transmissibility across a fault needs to be modified see the FAULTS and MULTFLT keywords in the GRID section for an alternative and less complicated method to modifying fault transmissibilities. Transmissibility between reservoir regions can be modified by using MULTREGT keyword, provided MULTNUM has been used to define the inter-region transmissibility region numbers for each grid block. Finally, the MULTX, MULTY and MULTZ series of keywords can be used to modify transmissibility between various cells. All the aforementioned keywords are described in the GRID section.

Example

```
--
--        MANUALLY DEFINE NON-NEIGHBOR CONNECTIONS
--
--        ------------ BOX -----------    -- TRANSNNC --
--        I1   J1   K1    I2   J2   K2
NNC
          1    1    1     1    1    2         0.2500     / SET NNC FOR FAULT
          1    1    2     1    1    3         0.2500     / SET NNC FOR FAULT
          1    1    3     1    1    4         0.2500     / SET NNC FOR FAULT
/
```

The above example defines the transmissibility between cells (1, 1, 1) and (1, 1, 2), (1, 1, 2) and (1, 1, 3) and finally between (1, 1, 3) and (1, 1, 4) to be 0.2500.

6.3.150 NODPPM – DEACTIVATE FRACTURE POROSITY-PERMEABILITY CALCULATION

The NODPPM keyword deactivates the default behavior of multiplying the fracture porosity by the fracture permeability to calculate the effective fracture permeability in dual porosity and dual permeability runs. Either the DUALPORO or DUALPERM keywords in the RUNSPEC section must be declared in the input file in order to use this keyword. If the default calculation is switched off by this keyword, then the effective fracture permeability is taken to be those entered for the fracture using the PERMX, PERMY and PERMZ keywords in the GRID section. If the keyword is absent from the input deck, then the entered PERMX, PERMY and PERMZ arrays for the fractures are multiplied by fracture PORO array values in order to obtain the effective fracture permeability.

See *NODPPM – Deactivate Fracture Porosity-Permeability Calculation* in the RUNSPEC section for a full description.

6.3.151 NOECHO – DEACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns off echoing of all the input files to the print file. Note by default echoing of the inputs files is active. but can subsequently be switched off by the NOECHO activation keyword.

See *NOECHO – Deactivate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

6.3.152 NOGGF – DEACTIVATE OUTPUT OF GRID GEOMETRY FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword deactivates the output of a standard GRID or extended GRID file, as well as the extensible EGRID file for post-processing applications.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       DEACTIVATE GRID GEOMETRY OUTPUT
--
NOGGF
```

The above example switches off the default behavior of writing out the grid geometry files.

6.3.153 NOWARN – DEACTIVATE WARNING MESSAGES

Turns off warning messages to be printed to the print file; note that this keyword is deactivated by default and can subsequently be switched off by the WARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN.

See *NOWARN – Deactivate Warning Messages* in the GLOBAL section for a full description.

6.3.154 NTG – DEFINE THE NET-TO-GROSS RATIO FOR ALL THE CELLS

Description

NTG defines the Net-to-Gross Ratio ("NTG") for all the cells in the model via an array. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	NTG	NTG is an array of real numbers greater than or equal to zero and less than or equal to one, that are assigned the net-to-gross ratio values for each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 200*0.850.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) Setting a cells NTG value to zero will make the cell inactive, similar to setting the cells ACTNUM property to zero.
2) The keyword is terminated by a "/".

Table 6.91: NTG Keyword Description

See also the PORO, PERMX, PERMY and PERMZ keywords to fully define a grid's properties.

Example

```
--
--        DEFINE GRID BLOCK NTG DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
NTG
          100*1.000   100*0.850   100*0.500                                    /
```

The above example defines a constant NTG of 1.00 for the first 100 cells, then 0.85 for the second 100 hundred cells, and finally 0.500 for the last 100 cell, for the 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.155 NXFIN – DEFINE THE NUMBER OF LGR GRID BLOCKS IN THE X-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

NXFIN defines the number of Local Grid Refinement ("LGR") cells within a global or host cell in the x-direction via a vector, as opposed to defining the size for each cell for a Cartesian LGR Grid. The LGR keyword in the RUNSPEC section should be activated to indicate an LGR is being used, and the keyword NXFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	NXFIN	NXFIN is a vector of integer numbers describing the number of LGR cells within each defined global or host grid block in the x-direction in a Cartesian LGR grid. Repeat counts may be used, for example 2*2.0.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NX parameter on the CARFIN keyword in the GRID section.
2) The keyword is terminated by a "/".

Table 6.92: NXFIN Keyword Description

See also the CARFIN, ENDFIN, NYFIN, and NZFIN keywords in the GRID section to fully define a Cartesian LGR grid model.

Example

```
--
--       CARFIN LGR GRID COMMANDS
--
--       LGR        ----- HOST GRID ------    -- CARFIN GRID --  MAX     HOST
--       NAME       I1  I2  J1  J2  K1  K2     NX    NY    NZ   WELLS   NAME
CARFIN
         LGR-OP01   24  25  87  87   1  50      8     1    50     1     GLOBAL /
--
--       DEFINE LGR GRID BLOCKS IN THE X-DIRECTION
--
NXFIN
         4  4                                                             /

ENDFIN
```

The above example splits the global cells (24-25,87, 1-50) into four and four LGR grid blocks in the x-direction, and since the HXFIN keyword has not been supplied, then the host cells will split into equal proportions.

6.3.156 NYFIN – DEFINE THE NUMBER OF LGR GRID BLOCKS IN THE Y-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

NYFIN defines the number of Local Grid Refinement ("LGR") cells within a global or host cell in the x-direction via a vector, as opposed to defining the size for each cell for a Cartesian LGR Grid. The LGR keyword in the RUNSPEC section should be activated to indicate an LGR is being used, and the keyword NYFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	NYFIN	NYFIN is a vector of integer numbers describing the number of LGR cells within each defined global or host grid block in the y-direction in a Cartesian LGR grid. Repeat counts may be used, for example 2*2.0.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NY parameter on the CARFIN keyword in the GRID section.
2) The keyword is terminated by a "/".

Table 6.93: NYFIN Keyword Description

See also the CARFIN, ENDFIN, NXFIN, and NZFIN keywords in the GRID section to fully define a Cartesian LGR grid model.

Example

```
--
--       CARFIN LGR GRID COMMANDS
--
--       LGR        ----- HOST GRID ------    -- CARFIN GRID --   MAX     HOST
--       NAME       I1  I2  J1  J2  K1  K2     NX    NY    NZ   WELLS   NAME
CARFIN
         LGR-OP01   24  24  86  87   1  50      1     8    50     1     GLOBAL /
--
--       DEFINE LGR GRID BLOCKS IN THE Y-DIRECTION
--
NYFIN
         4  4                                                              /

ENDFIN
```

The above example splits the global cells (24, 86-87,1-50) into four and four LGR grid blocks in the y-direction and since the HYFIN keyword has not been supplied, then the host cells will split into equal proportions.

6.3.157 NZFIN – DEFINE THE NUMBER OF LGR GRID BLOCKS IN THE Z-DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

NZFIN defines the number of Local Grid Refinement ("LGR") cells within a global or host cell in the z-direction via a vector, as opposed to defining the size for each cell for a Cartesian LGR Grid. The LGR keyword in the RUNSPEC section should be activated to indicate an LGR is being used, and the keyword NXFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	NZFIN	NZFIN is a vector of integer numbers describing the number of LGR cells within each defined global or host grid block in the x-direction in a Cartesian LGR grid. Repeat counts may be used, for example 2*2.0.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NX parameter on the CARFIN keyword in the GRID section.
2) The keyword is terminated by a "/".

Table 6.94: NZFIN Keyword Description

See also the CARFIN, ENDFIN, NXFIN, and NYFIN keywords in the GRID section to fully define a Cartesian LGR grid model.

Example

```
--
--       CARFIN LGR GRID COMMANDS
--
--       LGR        ----- HOST GRID ------    -- CARFIN GRID --  MAX     HOST
--       NAME       I1  I2  J1  J2  K1  K2     NX    NY    NZ   WELLS   NAME
CARFIN
         LGR-OP01   24  24  86  86   1  50      8     1    100    1     GLOBAL /
--
--       DEFINE LGR GRID BLOCKS IN THE Z-DIRECTION
--
NZFIN
         50*2                                                            /

ENDFIN
```

The above example splits the global cells (24, 86, 1-50) into two LGR grid blocks per host cell in the z-direction, and since the HZFIN keyword has not been supplied, then the host cells will split into equal proportions.

6.3.158 OLDTRAN – ACTIVATE CARTESIAN REGULAR GRID TRANSMISSIBILITIES

Description

This keyword switches on Cartesian Regular Grids geometry transmissibility calculation (or block centered transmissibility calculations), which is the default option for this type of grid. Grids defined by the DX, DY, and DZ series of keywords will always invoke this option by default.

For Irregular Corner-Point Grids defined by the COORD and ZCORN keywords Irregular Corner-Point Grid geometry transmissibility calculations should be activated via the NEWTRAN keyword. Again this is automatically invoked if this type of grid is being employed.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE CARTESIAN REGULAR GRID TRANSMISSIBILITIES
--
OLDTRAN
```

The above example manually activates Cartesian Regular Grid transmissibility calculations.

6.3.159 OLDTRANR – ACTIVATE RADIAL REGULAR GRID TRANSMISSIBILITIES

Description

This keyword switches on Radial Regular Grids geometry transmissibility calculation (or block centered transmissibility calculations), which is the default option for this type of grid. Grids defined by the DR, DTHETA, and DZ series of keywords will always invoke this option by default.

For Irregular Corner-Point Grids defined by the COORD and ZCORN keywords Irregular Corner-Point Grid geometry transmissibility calculations should be activated via the NEWTRAN keyword. Again this is automatically invoked if this type of grid is being employed.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE RADIAL REGULAR GRID TRANSMISSIBILITIES
--
OLDTRANR
```

The above example manually activates Radial Regular Grid transmissibility calculations.

6.3.160 OPERATE – DEFINE MATHEMATICAL OPERATIONS ON ARRAYS

Description

This keyword, OPERATE, defines mathematical operations on property arrays (NTG, PORO etc.) and optionally using another property array as input to the function. The keyword allows for various mathematical functions and their associated variables to be defined and applied to the selected array data. Input constants can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

No.	Name	Description	Default
1	Y	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and optionally enclosed in quotes.	None
2	I1	A positive integer that defines the lower bound of the array in the I-direction to be modified must be greater than or equal to one and less than or equal to I2 and NX.	1
3	I2	A positive integer that defines the upper bound of the array in the I-direction to be modified must be greater than or equal to I1 and less than or equal to NX	NX
4	J1	A positive integer that defines the lower bound of the array in the J-direction to be modified must be greater than or equal to one and less than or equal to J2 and NY.	1
5	J2	A positive integer that defines the upper bound of the array in the J-direction to be modified must be greater than or equal to J1 and less than or equal to NY.	NY
6	K1	A positive integer that defines the lower bound of the array in the K-direction to be modified must be greater than or equal to one and less than or equal to K2 and NZ.	1
7	K2	A positive integer that defines the upper bound of the array in the K-direction to be modified must be greater than or equal to K1 and less than or equal to NZ.	NZ
8	EQUATION	A defined character string enclosed in quotes that selects the mathematical function to be applied, using the X array and the ALPHA and BETA constants declared on this keyword. EQUATION should be set to one of the following character strings: 'MULTA' - $Y = \alpha X + \beta$ 'POLY' - $Y = Y + \alpha X^{\beta}$ 'SLOG' - $Y = 10^{\alpha X + \beta}$ 'LOG10' - $Y = \log(X)$ 'LOGE' - $Y = \ln(X)$ 'INV' - $Y = \frac{1}{X}$ 'MULTX' - $Y = \alpha X$ 'ADDX' - $Y = \alpha + X$ 'COPY' - $Y = X$ 'MAXLIM' - $Y = max(\alpha, X)$ 'MINLIM' - $Y = min(\alpha, X)$ 'MULTP' - $Y = \alpha X^{\beta}$ 'ABS' - $Y = \lvert(X)\rvert$ 'MULTIPLY' - $Y = XY$	None

No.	Name	Description	Default
9	X	The name of the array to be used as an input parameter. This is the keyword name identifying the property and is up to eight characters in length and optionally enclosed in quotes.	None
10	ALPHA	An integer or real value that is the α variable in the EQUATION function.	None
11	BETA	An integer or real value that is the β variable in the EQUATION function.	None

Notes:

1) Where NX, NY and NZ are the dimensions of the model as defined on the DIMENS keyword in the RUNSPEC section.
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.95: OPERATE Keyword Description

The applicable arrays for each section are defined in Table 6.96 as shown below.

OPERATE Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL	ENDNUM	PRESSURE		
DY	PORV	SWCR	EQLNUM	SWAT		
DZ	TRANX	SWU	FIPNUM	SGAS

NTG						
FLUXNUM						
MULTNUM						
MPANUM						
DIFFX						
DIFFY						
DIFFZ						
DIFFR						
DIFFTHT						

Table 6.96: OPERATE Keyword Applicable Arrays by Section

Note that care should be exercised when performing operations on integer array data as all transforms are performed using floating point arithmetic operations. In addition, operations on any of the transmissibility arrays (TRANX, TRANX-, TRANY, TRANY-, TRANZ, and TRANZ-) may result in untended consequences as these arrays have zero values on the boundary of the grid. In this use OPM ResInsight to verify and visually inspect the results.

Example

The first example uses the MULTP function combined with the Net-to-Gross (NTG) array to re-scale the MULTX, MULTY and MULTZ arrays to reduce the transmissibility in three separation reservoirs based on the reservoir quality (NTG).

```
--
--        MATHEMATICAL OPERATIONS ON ARRAYS BY CELL
--
--        OUTPUT   ---------- BOX ---------   OPERATION   INPUT    ALPHA    BETA
--        ARRAY    I1   I2    J1   J2    K1   K2  ---------   ARRAY    -----    ----
OPERATE
          MULTX    1*   1*    1*   1*      1  32  'MULTP'     NTG      1.00     0.75 / RES1
          MULTY    1*   1*    1*   1*      1  32  'MULTP'     NTG      1.00     0.75 / RES1
          MULTZ    1*   1*    1*   1*      1  32  'MULTP'     NTG      1.00     0.75 / RES1

          MULTX    1*   1*    1*   1*     34  64  'MULTP'     NTG      1.00     0.85 / RES2
          MULTY    1*   1*    1*   1*     34  64  'MULTP'     NTG      1.00     0.85 / RES2
          MULTZ    1*   1*    1*   1*     34  64  'MULTP'     NTG      1.00     0.85 / RES2

          MULTX    1*   1*    1*   1*     67  96  'MULTP'     NTG      1.00     0.50 / RES3
          MULTY    1*   1*    1*   1*     67  96  'MULTP'     NTG      1.00     0.50 / RES3
          MULTZ    1*   1*    1*   1*     67  96  'MULTP'     NTG      1.00     0.50 / RES3
/
```

The next example shows how to set the maximum gas saturation (SGU) based on the minimum (lowest) water saturation (SWL) when using the End-Point Scaling option.

```
--
--        MATHEMATICAL OPERATIONS ON ARRAYS
--
--        OUTPUT   ---------- BOX ---------   OPERATION   INPUT    ALPHA    BETA
--        ARRAY    I1   I2    J1   J2    K1   K2  ---------   ARRAY    -----    ----
OPERATE
          SGU      1*   1*    1*   1*    1*   1*  'MULTA'      SWL     -1.0     1.0      /
/
```

The above example set the maximum gas saturation to be one minus the minimum water saturation.

6.3.161 OPERATER – DEFINE MATHEMATICAL OPERATIONS ON ARRAYS BY REGION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The OPERATER keyword is similar to the OPERATE keyword in the GRID section, except it applies the mathematical operation on specific regions, whereas, OPERATE applies the operations on a cell by cell basis. Here the OPERATER keyword defines mathematical operations on property arrays (NTG, PORO etc.) and optionally using another property array as input to the function. The keyword allows for various mathematical functions and their associated variables to be defined and applied to the selected region data. Input constants can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

No.	Name	Description	Default
1	Y	The name of the array to be modified. This is the keyword name identifying the property and is up to eight characters in length and optionally enclosed in quotes.	None
2	REGION	REGION is a positive integer representing the region for which the EQUATION should be applied. The default is to use the region number from the OPERNUM keyword; however this can be reset to another region array via the ARRAY item on this keyword, provided the array exists at the time the keyword is declared in the input deck. Note also the OPERNUM keyword must precede the use of the OPERATER keyword.	0
3	EQUATION	A defined character string enclosed in quotes that selects the mathematical function to be applied, using the X array and the ALPHA and BETA constants declared on this keyword. EQUATION should be set to one of the following character strings: 'MULTA' - $Y = \alpha X + \beta$ 'POLY' - $Y = Y + \alpha X^{\beta}$ 'SLOG' - $Y = 10^{\alpha X + \beta}$ 'LOG10' - $Y = \log(X)$ 'LOGE' - $Y = \ln(X)$ 'INV' - $Y = \frac{1}{X}$ 'MULTX' - $Y = \alpha X$ 'ADDX' - $Y = \alpha + X$ 'COPY' - $Y = X$ 'MAXLIM' - $Y = max(\alpha, X)$ 'MINLIM' - $Y = min(\alpha, X)$ 'MULTP' - $Y = \alpha X^{\beta}$ 'ABS' - $Y = \lvert(X)\rvert$ 'MULTIPLY' - $Y = XY$	None
4	X	The name of the array to be used as an input parameter. This is the keyword name identifying the property and is up to eight characters in length and optionally enclosed in quotes.	None
5	ALPHA	An integer or real value that is the α variable in the EQUATION function.	None
6	BETA	An integer or real value that is the β variable in the EQUATION function.	None

No.	Name	Description	Default
7	ARRAY	The name of the array for which the REGION variable references. This can be any standard region array as declared in the REGION section (FIPNUM, PVTNUM, etc.), provided the array exists at the time the OPERATER keyword is invoked. In addition, the MULTNUM, FLUXNUM and OPERNUM may be used. Only the default value of OPERNUM is supported by OPM Flow.	OPERNUM

Notes:

1) Where the REGION should be less than or equal to the maximum number of regions as defined on the REGDIMS keyword for the FIPNUM and OPERNUM arrays or the GRIDOPTS keyword for the MULTNUM array in the RUNSPEC section..
2) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.97: OPERATE Keyword Description

The applicable arrays for each section are defined in Table 6.98 as shown below.

OPERATE Keyword And Variable Options By Section						
GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE
DX	DEPTH	SWL	ENDNUM	PRESSURE		
DY	PORV	SWCR	EQLNUM	SWAT		
DZ	TRANX	SWU	FIPNUM	SGAS		
PERMX	TRANY	SGL	IMBNUM	RV		
PERMY	TRANZ	SGCR	MISCNUM	RS		
PERMZ	DIFFX	SGU	PVTNUM	TBLK		
MULTX	DIFFY	KRW	ROCKNUM	GI		
MULTY	DIFFZ	KRO	SATNUM	OILAPI		
MULTZ	TRANR	KRG	WH2NUM	SALT		
DR	TRANTHT	PCG		GASCONC		
THETA	DIFFR	PCW		SOLVCONC		
PERMR	DIFFTHT			SOLVFRAC		
PERMTHT				SFOAM		
DZNET				SPOLY		
PORO						
NTG						
FLUXNUM						
MULTNUM						
MPANUM						
DIFFX						
DIFFY						
DIFFZ						
DIFFR						
DIFFTHT						

Table 6.98: OPERATE Keyword Applicable Arrays by Section

Note that care should be exercised when performing operations on integer array data as all transforms are performed using floating point arithmetic operations. In addition, operations on any of the transmissibility arrays (TRANX, TRANX-, TRANY, TRANY-, TRANZ, and TRANZ-) may result in unintended consequences as these arrays have zero values on the boundary of the grid. In this use OPM ResInsight to verify and visually inspect the results.

Note

The OPERATER and OPERATE keywords allow for great flexibility in generating or modifying the simulator's input arrays. In addition, OPM Flow also has a Python facility to manipulate and calculate data that offers even greater flexibility, but note that this feature is not compatible with the commercial simulator.

Finally, OPM ResInsight, the post-processing plotting software, has both Octave and Python scripting facilities that enable both data generation and visual inspection of the results. The resulting calculated arrays can then be exported from OPM ResInsight and "included" back into OPM Flow, thus maintaining compatibility with the commercial simulator.

Example

The first example uses the MULTP function combined with the Net-to-Gross (NTG) array to re-scale the MULTX, MULTY and MULTZ arrays to reduce the transmissibility in three separate reservoirs based on the reservoir quality (NTG). This keyword sequence should be in the GRID section.

```
--
--        MATHEMATICAL OPERATIONS ON ARRAYS BY REGION
--
--        OUTPUT    REGN    OPERATION    SOURCE    ALPHA    BETA     REGN
--        ARRAY     NUM     TYPE         ARRAY     CONST    CONST    ARRAY
OPERATER
          MULTX     1      'MULTP'       NTG       1.00     0.75         / RES1
          MULTY     1      'MULTP'       NTG       1.00     0.75         / RES1
          MULTZ     1      'MULTP'       NTG       1.00     0.75         / RES1

          MULTX     2      'MULTP'       NTG       1.00     0.85         / RES2
          MULTY     2      'MULTP'       NTG       1.00     0.85         / RES2
          MULTZ     2      'MULTP'       NTG       1.00     0.85         / RES2

          MULTX     3      'MULTP'       NTG       1.00     0.50         / RES3
          MULTY     3      'MULTP'       NTG       1.00     0.50         / RES3
          MULTZ     3      'MULTP'       NTG       1.00     0.50         / RES3
/
```

Notice that the ARRAY variable has been defaulted, resulting in OPERNUM being the regional array for the REGION variable.

The next example shows how to set the maximum gas saturation (SGU) based on the minimum (lowest) water saturation (SWL) when using the End-Point Scaling option, in the PROPS section.

```
--
--        MATHEMATICAL OPERATIONS ON ARRAYS
--
--        OUTPUT    REGN    OPERATION    SOURCE    ALPHA    BETA     REGN
--        ARRAY     NUM     TYPE         ARRAY     CONST    CONST    ARRAY
OPERATER
          SGU       1      'MULTA'       SWL       -1.0     1.0          /
          SGU       2      'MULTA'       SWL       -1.0     1.0          /
          SGU       3      'MULTA'       SWL       -1.0     1.0          /
/
```

The above example set the maximum gas saturation to be one minus the minimum water saturation for regions one to three.

The final example shows how to reset the FIPNUM array when the exported array from the earth model does not correspond to the simulator's desired numbering scheme.

```
--
--        MATHEMATICAL OPERATIONS ON ARRAYS BY REGION
--
--        RESET FIPNUM BASED ON MULTNUM AND OPERNUM
--
--        DESTIN    REGN    OPERATION    SOURCE    ALPHA    BETA  INPUT  SEGNUM    EQUIL
--        ARRAY     NUM     TYPE         ARRAY     CONST    CONST ARRAY  NUMBER    NUMBER
OPERATER
          FIPNUM     26     'MULTA'    'MULTNUM'  0.00      1           /  26        1
          FIPNUM     44     'MULTA'    'MULTNUM'  0.00      2           /  44        2
          FIPNUM     62     'MULTA'    'MULTNUM'  0.00      3           /  62        3
          FIPNUM     98     'MULTA'    'MULTNUM'  0.00      4           /  98        4
          FIPNUM    116     'MULTA'    'MULTNUM'  0.00      5           / 116        5
          FIPNUM    134     'MULTA'    'MULTNUM'  0.00      6           / 134        6
          FIPNUM     46     'MULTA'    'MULTNUM'  0.00      7           /  46        7
          FIPNUM     64     'MULTA'    'MULTNUM'  0.00      8           /  64        8
          FIPNUM     82     'MULTA'    'MULTNUM'  0.00      9           /  82        9
          FIPNUM    226     'MULTA'    'MULTNUM'  0.00     10           / 226       10
          FIPNUM    262     'MULTA'    'MULTNUM'  0.00     11           / 262       11
          FIPNUM    280     'MULTA'    'MULTNUM'  0.00     12           / 280       12
          FIPNUM    298     'MULTA'    'MULTNUM'  0.00     13           / 298       13
          FIPNUM     33     'MULTA'    'MULTNUM'  0.00     14           /  33       14
          FIPNUM     51     'MULTA'    'MULTNUM'  0.00     15           /  51       15
          FIPNUM    105     'MULTA'    'MULTNUM'  0.00     16           / 105       16
          FIPNUM    159     'MULTA'    'MULTNUM'  0.00     17           / 159       17
          FIPNUM    195     'MULTA'    'MULTNUM'  0.00     18           / 195       18
          FIPNUM    267     'MULTA'    'MULTNUM'  0.00     19           / 267       19
          FIPNUM    303     'MULTA'    'MULTNUM'  0.00     20           / 303       20
          FIPNUM    321     'MULTA'    'MULTNUM'  0.00     21           / 321       21
          FIPNUM    339     'MULTA'    'MULTNUM'  0.00     22           / 339       22
          FIPNUM     54     'MULTA'    'MULTNUM'  0.00     23           /  54       23
          FIPNUM     72     'MULTA'    'MULTNUM'  0.00     24           /  72       24
          FIPNUM    108     'MULTA'    'MULTNUM'  0.00     25           / 108       25
          FIPNUM    144     'MULTA'    'MULTNUM'  0.00     26           / 144       26
          FIPNUM    270     'MULTA'    'MULTNUM'  0.00     27           / 270       27
/
```

Note that operation can only be done in the REGION section as FIPNUM is only available for use in this section and that the ARRAY variable has been defaulted, resulting in OPERNUM being the regional array for the REGION variable.

6.3.162 OPERNUM – DEFINE REGIONS FOR MATHEMATICAL OPERATIONS ON ARRAYS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the OPERATER region numbers for each grid block. The OPERNUM keyword defines the region numbers for each grid block, as such there must be one entry for each cell in the model. The array can also be used with the EQUALREG, ADDREG, COPYREG, MULTIREG, MULTREGP and MULTREGT keywords, as well as the OPERATER keyword in calculating various grid properties in the GRID and REGION section.

No.	Name	Description	Default
1	OPERNUM	OPERNUM defines an array of positive integers greater than or equal to one that assigns a grid cell to a particular OPERNUM region. The maximum number of OPERNUM regions is set by the NOPREG variable on the REGDIMS keyword in the RUNSPEC section. Note that the default value of zero implies that the calculations requested by the OPERATER keyword will not be performed.	0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.99: OPERNUM Keyword Description

Examples

The example below sets three OPERNUM regions for a 4 x 5 x 2 model.

```
--
--        DEFINE OPERNUM REGIONS FOR ALL CELLS
--
OPERNUM
          2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
          3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--        ARRAY       CONSTANT     ---------- BOX ---------
--                                 I1  I2   J1  J2   K1  K2
EQUALS
          OPERNUM     1            1*  1*   1*  1*   1*  1* / SET REGION 1
          OPERNUM     2            1   2    1   2    1   1  / SET REGION 2
          OPERNUM     3            1   2    1   2    2   2  / SET REGION 3
/
```

One can then increase PERMX by 25% in region three only.

```
--
--        MULTIPLY AN ARRAY BY A CONSTANT BASED ON A REGION NUMBER
--
--        ARRAY     CONSTANT  REGION   REGION ARRAY
--                  VALUE     NUMBER    M / F / O
MULTIREG
          PERMX     1.25      3         O                  /
/
```

6.3.163 OUTRAD - DEFINE THE OUTER RADIUS OF A RADIAL GRID

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

OUTRAD defines the OUTER radius of the reservoir model for a radial or spider grid geometry. The RADIAL or SPIDER keyword in the RUNSPEC should be activated to indicate that radial or spider geometry is being used.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	OUTRAD	A single real positive number greater than INRAD defining the outer radius of a radial grid.			
		feet	m	cm	None
Notes: 1) The keyword is terminated by a "/".					

Table 6.100: OUTRAD Keyword Description

Note that the SPIDER keyword activates OPM Flow's radial grid geometry option for the model. This keyword will create a spiderweb-shaped grid based on a corner-point grid using the standard radial grid keywords: INRAD, DRV, DTHETAV, DZ/DZV etc. in the GRID the section. A spider grid can be viewed in 3D in OPM ResInsight unlike radial grids that cannot be viewed in the software. To overcome this, the simulator now converts radial grids to Irregular Corner-Point Grids and adjusts the model's pore volume to reflect radial coordinates; thus, overcoming the display limitation.

The keyword allows for an alternative method of entering the size of the R direction grid cells instead of entering the data using the DR or DRV keywords in the GRID section. Given the internal radius set by the INRAD keyword, the external radius set by the OUTRAD keyword and the number of grid cells in the R direction set by the NX variable on the DIMENS keyword in the RUNSPEC section, the R direction cells sizes are computed automatically on a geometric spacing, as defined by:

$$\frac{R_i}{R_{i-1}} = \left(\frac{OUTRAD}{R_{i_j-1}}\right)^{\frac{1}{(NX - i_j + 1)}} \tag{6.12}$$

or

$$R_i = \left(R_{i_j-1}\right)\left(\frac{OUTRAD}{R_{i_j-1}}\right)^{\frac{(i - i_j + 1)}{(NX - i_j + 1)}} \tag{6.13}$$

and the DR value for the i^{th} cell, that is the value that can also be manually entered on the DR keyword in the GRID section, is given by:

$$DR_i = R_i - R_{i-1} \tag{6.14}$$

Where:

DR_i = DR value for the i^{th} cell
R_i = current total radius for the i radii.
Ri-1 = total radius for the i – 1 radii.

NX (NR) = number of radial grid cells excluding the inner radius
OUTRAD = the outer radius of the radial grid, the value includes the inner radius.

For example, given an inner radius set to 0.25, an outer radius of 2,050 and the number of cells in the R direction set to ten, then Table 6.101 shows the grid size calculations.

OUTRAD Radial Grid Example			
INRAD	0.25		
OUTRAD	2050.0		
NX	10		
NX	**Ri**	**DR**	**Ratio**
0	0.250	0.250	
1	0.616	0.366	1.463
2	1.516	0.900	2.463
3	3.733	2.217	2.463
4	9.193	5.460	2.463
5	22.638	13.445	2.463
6	55.748	33.109	2.463
7	137.281	81.533	2.463
8	338.058	200.777	2.463
9	832.477	494.420	2.463
10	2050.000	1217.523	2.463
Total		**2050.000**	

Table 6.101: OUTRAD Radial Grid Example

See also the DR, DRV, DTHETA, DTHETAV and TOPS keywords to fully define a Radial or Spider Grid.

Example

```
--
--       INNER RADIUS OF FIRST GRID BLOCK IN THE RADIAL DIRECTION
--
INRAD
         0.25                                                                  /
--
--       OUTER RADIUS OF FIRST GRID BLOCK IN THE RADIAL DIRECTION
--
OUTRAD
         2050.0                                                                /
```

The above example defines the inner radius to be 0.25 and the outer radius to be 2,050 feet. Note that the outer radius includes the inner radius.

6.3.164 PARAOPTS – DEFINE PARALLEL RUN OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PARAOPTS keyword defines various options for parallel runs, for when the Parallel option has been invoked by the PARALLEL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to run OPM Flow in parallel mode.

6.3.165 PEBI – ACTIVATE AND DEFINED PEBI GRID OPTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PEBI activates the unstructured Perpendicular Bisector ("PEBI")[125] and [126] loading of grid data generated by an external pre-processing program for generating simulation grids.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	OPTION1	A defined character string that activates or deactivates the checking of negative transmissibility values. OPTION1 should be set to YES to check for negative values, or NO switches off this option.	NO
2	OPTION2	A defined character string that activates or deactivates the calculation of pore volumes and transmissibilities. OPTION2 should be set to YES if the pore volumes and transmissibilities are provided, or NO for the values to calculated by the simulator.	NO

Table 6.102: PEBI Keyword Description

Example

```
--
--      OPTION1  OPTION2
--      CHECK    CALCULATE
PEBI
        NO       YES                                                    /
```

The above example switches off the negative transmissibility check and requests that the simulator calculates pore volumes and transmissibilities as they are not provided by the input data.

[125] *Heinemann, Z.E. and Brand, C.W. 1988. Gridding Techniques in Reservoir Simulation. Proc., First Intl. Forum on Reservoir Simulation, Alpbach, Austria, 339.*

[126] *Heinemann, Z.E., Brand, C.W., Munka, M. et al. 1991. Modeling Reservoir Geometry With Irregular Grids. SPE Res Eng 6 (2): 225–232. SPE-18412-PA. http://dx.doi.org/10.2118/18412-PA*

6.3.166 PERMAVE – DEFINE AVERAGE TRANSMISSIBILITY COEFFICIENTS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PERMAVE keyword defines the three directional exponent coefficients used to average the grid block permeabilities between two neighboring cells when calculating the transmissibility between the two blocks. The keyword can be used to change from the default weighted harmonic averaging (coefficient set equal to -1), to geometric (coefficient equal to zero), or to arithmetic averaging (coefficient equal to 1). The three coefficients represent the averaging in the x-, y- and z-directions.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.167 PERMJFUN – DEFINE LEVERETT J-FUNCTION PERMEABILITY FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PERMJFUN defines the permeability to be used in de-normalizing the Leverett J-Functions[127] for when the PERM variable on the JFUNC or the JFUNCR keyword in the GRID section has been set to "U", as oppose to using PERMX, PERMY, PERMZ arrays etc.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PERMJFUN	PERMJFUN is an array of real positive numbers assigning the permeability to be used in de-normalizing the Leverett J-Function to each cell in the model. Repeat counts may be used, for example 20*100.0.			
		mD	mD	mD	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.103: PERMJFUN Keyword Description

For grid blocks that have not been assigned a PERMJFUN value the default directional permeability will be used, that is the average of PERMX and PERMY.

See also the PERMX, PERMY and PERMZ keywords to fully define the permeability for the model.

Example

```
--
--       DEFINE GRID BLOCK PERMJFUN FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PERMJFUN
         100*500.0   100*50.0   100*200.0                                    /
```

The above example defines the PERMJFUN to be 500.0, 50.0, and 200.0 for the first, second and third layers in the model for all 300 cells, as defined by the DIMENS keyword in the RUNSPEC section.

[127] *Leverett, M. C.; "Capillary Behaviour in Porous Solids", Trans. AIME (1941) 142, 152-168.*

6.3.168 PERMR – DEFINE THE PERMEABILITY FOR EACH CELL IN THE R DIRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PERMR sets the permeability for each cell in the R direction in a radial geometry grid. The RADIAL or SPIDER keywords in the RUNSPEC should be activated to indicate that radial or spider geometry is being used.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PERMR	PERMR is an array of real positive numbers assigning the permeability in the R direction to each cell in the model. This equivalent to PERMX in a Cartesian grid. Repeat counts may be used, for example 20*100.0.			
		mD	mD	mD	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.104: PERMR Keyword Description

Note that the SPIDER keyword activates OPM Flow's radial grid geometry option for the model. This keyword will create a spiderweb-shaped grid based on a corner-point grid using the standard radial grid keywords: INRAD, DRV, DTHETAV, DZ/DZV etc. in the GRID the section. A spider grid can be viewed in 3D in OPM ResInsight unlike radial grids that cannot be viewed in the software. To overcome this, the simulator now converts radial grids to Irregular Corner-Point Grids and adjusts the model's pore volume to reflect radial coordinates; thus, overcoming the display limitation.

See also the PERMTHT and PERMZ keywords to fully define the permeability for a radial or spider grid model.

Example

```
--
--       DEFINE GRID BLOCK PERMR DATA FOR ALL CELLS (BASED ON NR x NY x NZ = 300)
--
PERMR
         100*500.0   100*50.0   100*200.0                                    /
```

The above example defines the PERMR to be 500.0, 50.0, and 200.0 for the first, second and third layers in the model for all 300 cells, as defined by the DIMENS keyword (10, 10, 3) in the RUNSPEC section.

6.3.169 PERMTHT – DEFINE THE PERMEABILITY FOR EACH CELL IN THE THETA DIRECTION

Description

PERMTHT sets the permeability for each cell in the THETA direction in a radial geometry grid. The RADIAL or SPIDER keyword in the RUNSPEC should be activated to indicate that radial or spider geometry is being used.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PERMTHT	PERMTHT is an array of real positive numbers assigning the permeability in the THETA direction to each cell in the model. This equivalent to PERMY in a Cartesian grid. Repeat counts may be used, for example 20*100.0.			
		mD	mD	mD	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.105: PERMTHT Keyword Description

Note that the SPIDER keyword activates OPM Flow's radial grid geometry option for the model. This keyword will create a spiderweb-shaped grid based on a corner-point grid using the standard radial grid keywords: INRAD, DRV, DTHETAV, DZ/DZV etc. in the GRID the section. A spider grid can be viewed in 3D in OPM ResInsight unlike radial grids that cannot be viewed in the software. To overcome this, the simulator now converts radial grids to Irregular Corner-Point Grids and adjusts the model's pore volume to reflect radial coordinates; thus, overcoming the display limitation.

See also the PERMR and PERMZ keywords to fully define the permeability for a radial or spider grid model.

Example

```
--
--       DEFINE GRID BLOCK PERMTHT DATA FOR ALL CELLS (NX x NY x NZ = 300)
--
PERMTHT
         100*500.0   100*50.0   100*200.0                                  /
```

The above example defines the PERMTHT to be 500.0, 50.0, and 200.0 for the first, second and third layers in the model for all 300 cells, as defined by the DIMENS keyword (10, 10, 3) in the RUNSPEC section.

6.3.170 PERMX - DEFINE THE PERMEABILITY IN THE X DIRECTION FOR ALL THE CELLS

Description

PERMX defines the permeability in the X direction for all the cells in the model via an array. The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PERMX	PERMX is an array of real positive numbers assigning the permeability in the X direction to each cell in the model. Repeat counts may be used, for example 20*100.0.			
		mD	mD	mD	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.106: PERMX Keyword Description

See also the PERMY and PERMZ keywords to fully define the permeability for the model.

Example

```
--
--       DEFINE GRID BLOCK PERMX DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PERMX
         100*500.0   100*50.0   100*200.0                                    /
```

The above example defines the PERMX to be 500.0, 50.0, and 200.0 for the first, second and third layers in the model for all 300 cells, as defined by the DIMENS keyword in the RUNSPEC section.

6.3.171 PERMY - DEFINE THE PERMEABILITY IN THE Y DIRECTION FOR ALL THE CELLS

Description

PERMY defines the permeability in the Y direction for all the cells in the model via an array. The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PERMY	PERMY is an array of real positive numbers assigning the permeability in the Y direction to each cell in the model. Repeat counts may be used, for example 20*100.0.			
		mD	mD	mD	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.107: PERMY Keyword Description

See also the PERMX and PERMZ keywords to fully define the permeability for the model.

Example

```
--
--       DEFINE GRID BLOCK PERMY DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PERMY
         100*500.0   100*50.0   100*200.0                                    /
```

The above example defines the PERMY to be 500.0, 50.0, and 200.0 for the first, second and third layers in the model for all 300 cells, as defined by the DIMENS keyword in the RUNSPEC section.

6.3.172 PERMZ - DEFINE THE PERMEABILITY IN THE Z DIRECTION FOR ALL THE CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PERMZ defines the permeability in the Z direction for all the cells in the model via an array. The keyword can be used for all grid types, except for the Radial Grid geometry.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PERMZ	PERMZ is an array of real positive numbers assigning the permeability in the Z direction to each cell in the model. Repeat counts may be used, for example 200*50.0.			
		mD	mD	mD	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.108: PERMZ Keyword Description

Note

Although PERMX and PERMY are commonly set to be equal, PERMZ is typically not equal to either PERMX or PERMY. Normally PERMZ is set as a fraction of PERMX with typical values ranging from 0.1 to 0.5 times PERMX.

See also the PERMX and PERMY keywords to fully define the permeability for the model.

Example

The example below defines the PERMZ to be 50.0, 5.0, and 20.0 for the first, second and third layers in the model for all 300 cells, as defined by the DIMENS keyword in the RUNSPEC section.

```
--
--       DEFINE GRID BLOCK PERMZ DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PERMZ
         100*50.0    100*5.0   100*20.0                                    /
```

The next example sets PERMX to be 500.0, 50.0, and 200.0 for the first, second and third layers in the model for all 300 cells, as defined by the DIMENS keyword in the RUNSPEC section. It then copies the PERMX values to the PERMY and PERMZ arrays, and finally multiplies PERMZ by 0.1 times to get the final values for PERMZ.

```
--
--       DEFINE GRID BLOCK PERMX DATA FOR ALL CELLS
--
PERMX
         100*500.0   100*50.0   100*200.0                                    /
--
--       SOURCE      DESTIN.      ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
COPY
         PERMX       PERMY        1*  1*   1*  1*   1*  1* / CREATE PERMY
         PERMX       PERMZ        1*  1*   1*  1*   1*  1* / CREATE PERMZ
/
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
MULTIPLY
         PERMZ       0.10000      1*  1*   1*  1*   1*  1* / PERMZ * 0.1
/
```

The above sequence of keywords is quite common in input decks, that is copying the PERMX data to the PERMY and PERMZ arrays and then adjusting the PERMY and PERMZ arrays as required using the MULTIPLY keyword.

6.3.173 PETGRID – LOAD A GENERIC SIMULATION GRID FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PETGRID keyword instructs the simulator to load a Generic Simulation Grid (*.GSG) file that contains grid geometry data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.174 PINCH – DEFINE PINCH-OUT LAYER OPTIONS

Description

The PINCH keyword defines the parameters used to control the generation of Non-Neighbor Connections ("NNCs") in the vertical (K) direction due to layers pinching out. This keyword is applied to all layers in the model as opposed to the PINCHREG keyword that offers more flexibility by applying the pinch-out controls to various regions in the model defined by the PINCHNUM keyword.

OPM Flow will automatically generate connections between non neighbor cells in the vertical direction based on the parameters on this keyword.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PINCHTHK	A real number defining the pinch-out threshold thickness for any cell. NNCs are generated across inactive cells having a vertical thickness less than PINCHTHK.			
		ft. 0.001	m 0.001	cm 0.001	Defined
2	PINCHOPT	A character string controlling the generation of pinch-outs when the MINPV keyword has been used to deactivate cells with small pore volumes. PINCHOPT can either be set to: 1) GAP to allow the generation of NNCs across cells that have been made inactive with the MINPV keyword when the thickness is greater than PINCHTHK threshold. 2) NOGAP to enforce the strict adherence to the PINCHTHK threshold whether or not cells have been made inactive due to the MINPV keyword.			GAP
3	PINCHGAP	A real number defining the maximum "empty" thickness allowed between grid blocks in adjacent grid layers for a non-zero transmissibility to exist between them.			
		ft. 1.0E20	m 1.0E20	cm 1.0E20	Defined
4	PINCHCAL	A character string controlling the calculation of the pinch-out transmissibilities. PINCHCAL can either be set to: 1) TOPBOT results in the pinch-out transmissibility being calculated from the half-cell Z-direction transmissibilities of the active cells on either side of the pinched-out layers. 2) ALL results in the pinch-out transmissibility being calculated from the Z-direction transmissibilities harmonic average of all the cells between the active cells on either side of the pinched-out layers.			TOPBOT

No.	Name	Description			Default
		Field	Metric	Laboratory	
5	PINCHMUL	A character string controlling the calculation of the pinch-out transmissibilities when adjustments have been made by the MULTZ keyword. PINCHMUL can either be set to: 1) TOP results in the pinch-out transmissibility being calculated from the active cell at the top of the pinch-out. 2) ALL results in the pinch-out transmissibility being calculated from the minimum value of the MULTZ of the active cell at the top of the pinch-out and all the inactive cells in the pinch-out vertical column. Note if PINCHCAL has been set equal to ALL then PINCHMUL is reset to TOP, irrespective of the entered value for PINCHMUL.			TOP
Notes: 1) The keyword is terminated by a "/".					

Table 6.109: PINCH Keyword Description

Examples

The first example below will create NNCs between the cells above and below any cell having vertical thickness less than 0.01 in either feet or metres.

```
--
--       SET PINCH-OUT PARAMETERS FOR CALCULATING PINCH-OUT PROPERTIES
--
PINCH
--       THRESHOLD   GAP      EMPTY   TRANS    MULTZ
--       THICKNESS   NO GAP   GAP     CALC     CALC
         0.01        1*       1*      1*       1*                    /
```

For the second example, the MINPV keyword is used to set the minimum pore volume to 500 m3 (metric units) and then the PINCH keyword is invoked with PINCHGAP set equal to GAP, as follows:

```
--
--       MINIMUM PORE VOLUME FOR ACTIVE CELLS
--
MINPV
         500.0                                                         /
--
--       SET PINCH-OUT CRITERIA FOR THE MODEL
--
PINCH
--       THRESHOLD   GAP      EMPTY   TRANS    MULTZ
--       THICKNESS   NO GAP   GAP     CALC     CALC
         0.1         GAP       1*    1*       1*                    /
```

In the above example the MINPV keyword will deactivate all cells with pore volumes less than 500 m3. These deactivated cells are inactive in the model and therefore are not included in the flow calculations; however, by default they will result in no-flow barriers but may not be thin enough for PINCH to create NNCs across them. By setting PINCHGAP equal to GAP on the PINCH keyword (the default setting), then OPM Flow generates NNCs across the cells that have been deactivated by the MINPV keyword. However, in this case there may be grid blocks in the model with a pore volume greater than MINPV but a thickness less than the pinch-out threshold. These cells will not be deactivated by the PINCH keyword.

6.3.175 PINCHNUM – DEFINE PINCH-OUT REGIONS FOR THE PINCHREG KEYWORD

Description

The PINCHNUM keyword defines the pinch-out region numbers for each grid block, as such there must be one entry for each cell in the model. The array is used with the PINCHREG keyword to set the pinch-out options and threshold thickness for each region.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	PINCHNUM	PINCHNUM defines an array of positive integers assigning a grid cell to a particular PINCHNUM region. The maximum number of PINCHNUM regions is set by the NRPINC variable on the GRIDOPTS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.110: PINCHNUM Keyword Description

Example

The example below sets defines three PINCHNUM regions for various layers in a model based on the model's layering.

```
--
--        ARRAY       CONSTANT     ---------- BOX ---------
--                                 I1  I2   J1  J2   K1  K2
EQUALS
          MULTNUM     1            1*  1*   1*  1*   1*  1* / SET REGION 1
          MULTNUM     2            1   2    1   2    10  50 / SET REGION 2
          MULTNUM     3            1   2    1   2    51 100 / SET REGION 3
/
```

One can then set the pinch-out criteria for each region.

```
--
--        SET PINCH-OUT CRITERA VIA THE PINCHNUM REGION
--
PINCHREG
--        THRESHOLD   GAP      EMPTY    TRANS
--        THICKNESS   NO GAP   GAP      CALC
          0.1         1*       1*       1*                  / PINCHNUM 01
          1.0         1*       10       1*                  / PINCHNUM 02
          1.0         NOGAP    20       1*                  / PINCHNUM 03
```

The above example sets the default pinch-out criteria for grid blocks defined as region one via the PINCHNUM array and different criteria for regions two and three.

6.3.176 PINCHOUT - DEFINE PINCH-OUT LAYERS OPTION (FIXED)

Description

The PINCHOUT keyword activates the generation of Non-Neighbor Connections ("NNCs") in the vertical (K) direction due to layers pinching out, using a constant threshold thickness of 0.001 for all unit systems. See also the PINCH keyword in the GRID section that allows for specifying the threshold thickness and other parameters on a layer basis, and the PINCHREG keyword that applies the pinch-out controls to various regions in the model defined by the PINCHNUM keyword.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

The example will create NNCs between the cells above and below any cell having vertical thickness less than 0.001 in either feet or metres.

```
--
--       SET PINCH-OUT CRITERA WITH CONSTANT THRESHOLD THICKNESS OF 0.001
--
PINCHOUT
```

6.3.177 PINCHREG - DEFINE PINCH-OUT REGION OPTIONS

Description

The PINCHREG keyword defines the parameters used to control the generation of Non-Neighbor Connections ("NNCs") in the vertical (K) direction due to layers pinching out in combination with the PINCHNUM keyword. This allows different regions in the model to use different criteria in controlling the how pinch-outs are generated. The keyword should contain NRPINC records defining the criteria for each pinch-out region defined with the PINCHNUM keyword. NRPINC is the maximum number of PINCHNUM regions defined via the GRIDOPTS keyword in the RUNSPEC section.

An alternative method to set the pinch-out criteria is to use the PINCH keyword, that applies the criteria to the whole model.

OPM Flow will automatically generate connections between non neighbor cells in the vertical direction based on the parameters on this keyword.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PINCHTHK	A real number defining the pinch-out threshold thickness for any cell. NNCs are generated across inactive cells having a vertical thickness less than PINCHTHK.			
		ft. 0.001	m 0.001	cm 0.001	Defined
2	PINCHOPT	A character string controlling the generation of pinch-outs when the MINPV keyword has been used to deactivate cells with small pore volumes. PINCHOPT can either be set to: 1) GAP to allow the generation of NNCs across cells that have been made inactive with the MINPV keyword when the thickness is greater than PINCHTHK threshold. 2) NOGAP to enforce the strict adherence to the PINCHTHK threshold whether or not cells have been made inactive due to the MINPV keyword.			GAP
3	PINCHGAP	A real number defining the maximum "empty" thickness allowed between grid blocks in adjacent grid layers for a non-zero transmissibility to exist between them.			
		ft. 1.0E20	m 1.0E20	cm 1.0E20	Defined
4	PINCHCAL	A character string controlling the calculation of the pinch-out transmissibilities. PINCHCAL can either be set to: 1) TOPBOT results in the pinch-out transmissibility being calculated from the half-cell Z-direction transmissibilities of the active cells on either side of the pinched-out layers. 2) ALL results in the pinch-out transmissibility being calculated from the Z-direction transmissibilities harmonic average of all the cells between the active cells on either side of the pinched-out layers.			TOPBOT

No.	Name	Description			Default
		Field	Metric	Laboratory	
5	PINCHMUL	A character string controlling the calculation of the pinch-out transmissibilities when adjustments have been made by the MULTZ keyword. PINCHMUL can either be set to: 1) TOP results in the pinch-out transmissibility being calculated from the active cell at the top of the pinch-out. 2) ALL results in the pinch-out transmissibility being calculated from the minimum value of the MULTZ of the active cell at the top of the pinch-out and all the inactive cells in the pinch-out vertical column. Note if PINCHCAL has been set equal to ALL then PINCHMUL is reset to TOP, irrespective of the entered value for PINCHMUL.			TOP
Notes: 1) The keyword should contain NRPINC records defining the criteria for each pinch-out region defined with the PINCHNUM keyword. NRPINC is the maximum number of PINCHNUM regions defined via the GRIDOPTS keyword in the RUNSPEC section. 2) Each record must be terminated by a "/" there is no keyword terminating "/".					

Table 6.111: PINCHREG Keyword Description

Example

```
--
--       SET PINCH-OUT CRITERA VIA THE PINCHNUM REGION
--
PINCHREG
--       THRESHOLD   GAP      EMPTY   TRANS
--       THICKNESS   NO GAP   GAP     CALC
         0.1         1*       1*      1*                  / PINCHNUM 01
         1.0         1*       10      1*                  / PINCHNUM 02
         1.0         NOGAP    20      1*                  / PINCHNUM 03
```

The above example sets the default pinch-out criteria for grid blocks defined as region one via the PINCHNUM array and different values for regions two and three.

6.3.178 PINCHXY – DEFINE PINCH-OUT AREAL OPTIONS

Description

The PINCHXY keyword defines the x-direction and y-direction threshold thickness used to control the generation of Non-Neighbor Connections ("NNCs") in the x- and y- directions for missing cells in the areal plane.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PINCHTHX	A real number defining the pinch-out threshold width for any cell in the x-direction. NNCs are generated across inactive cells having a width less than PINCHTHX in the x-direction.			
		ft. 0.001	m 0.001	cm 0.001	Defined
2	PINCHTHY	A real number defining the pinch-out threshold width for any cell in the y-direction. NNCs are generated across inactive cells having a width less than PINCHTHY in the y-direction.			
		ft. 0.001	m 0.001	cm 0.001	Defined
Notes: 1) The keyword is terminated by a "/".					

Table 6.112: PINCHXY Keyword Description

Example

The example below will create NNCs between the cells in the areal plane having cell widths less than 0.01 in either feet or metres in both the x- and y-directions.

```
--
--        SET PINCH-OUT PARAMETERS FOR AREAL PLANE
--
PINCHXY
--        X-DIRC      Y-DIRC
--        THRESHOLD   THRESHOLD
--
          0.01        0.01                                    /
```

6.3.179 PORO - DEFINE THE POROSITY VALUES FOR ALL THE CELLS

Description

PORO defines the porosity for all the cells in the model via an array. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PORO	PORO is an array of real positive numbers that are greater than or equal to zero and less than or equal to one that are the porosity values for each cell in the model. Repeat counts may be used, for example 3000*0.15			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.113: PORO Keyword Description

See also the NTG, PERMX, PERMY and PERMX keywords to fully define a grid's properties

Example

```
--
--    DEFINE GRID BLOCK POROSITY DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PORO
      300*0.300                                                              /
```

The above example defines a constant porosity of 0.300 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.180 PYEND – END THE DEFINITION OF A PYINPUT SECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PYINPUT and PYEND keywords are a part of OPM Flow's Python scripting facility that processes standard Python commands that can be used to manipulate and define the simulators input parameters during processing of the input deck. The main purpose of the facility is to script the construction of the various keywords.

PYINPUT declares the start of a PYINPUT Definition Section on a single separate line, which is then followed by various standard Python commands, with one command per line. A PYINPUT Definition Section is terminated by a PYEND keyword (this keyword) on a separate single line.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Although this keyword is read by OPM Flow and the script processing has been implemented, one should use caution when using this facility as it may result in OPM Flow aborting. This is because the PYINPUT facility allows the user to implement complex functionality and the implementation is new for the 2020-04 release. Users should therefore use caution when using this facility.

Note

This is an OPM Flow specific keyword for the simulator's scripting facility using the standard Python interpreter, as such it gives more flexibility than the commercial simulator's data editing keywords (ADD, EQUAL, MULTIPLY, etc.), although OPM Flow also supports these keywords as well.

The PYINPUT facility should be considered experimental as details of the OPM Flow - Python interface might change for future releases. In particular, the current implementation is quite minimal; however, future releases are expected to add more entry points in the simulator's deck class which can be used to manipulate the input deck as the data is loaded. As a user you are encouraged to come with wishes in this regard.

The PYINPUT facility is very powerful and allows for any piece of Python code to be included and run, including potentially malicious code. The important point is to scrutinize the Python code in between PYINPUT and PYEND in a deck you receive from other parties.

See also the PYACTION keyword in the SCHEDULE section which is also part of OPM Flow's Python scripting facility, that loads a standard Python script file that can be used to define a series of conditions and actions as the simulation proceeds through time.

Example

The example shows how to construct the DX variable in the GRID section and to add the resulting DX array as part of the input deck.

```
--
--       START OF PYINPUT SECTION
--
PYINPUT
#
# Import Numpy Model
#
import numpy as np
#
# Define DX and Get the Input Decks Unit Systems
#
dx = np.array([100.0, 100.0, 100.0, 100.0])
active_unit_system  = context.deck.active_unit_system()
default_unit_system = context.deck.default_unit_system()
#
# Set DX in the Input Deck
#
kw = context.DeckKeyword( context.parser['DX'], dx, active_unit_system,
default_unit_system )
context.deck.add(kw)

PYEND
```

The active Parser objects are accessible as context.parser and the active Deck object is available as context.deck.

6.3.181 PYINPUT – DEFINE THE START OF A PYINPUT SECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PYINPUT and PYEND keywords are a part of OPM Flow's Python scripting facility that processes standard Python commands that can be used to manipulate and define the simulators input parameters during processing of the input deck. The main purpose of the facility is to script the construction of the various keywords used by the simulator.

PYINPUT declares the start of a PYINPUT Definition Section on a single separate line, which is then followed by various standard Python commands, with one command per line. A PYINPUT Definition Section is terminated by a PYEND keyword on a separate single line.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Although this keyword is read by OPM Flow and the script processing has been implemented, one should use caution when using this facility as it may result in OPM Flow aborting. This is because the PYINPUT facility allows the user to implement complex functionality and the implementation is new for the 2020-04 release. Users should therefore use caution when using this facility.

Note

This is an OPM Flow specific keyword for the simulator's scripting facility using the standard Python interpreter, as such it gives more flexibility than the commercial simulator's data editing keywords (ADD, EQUAL, MULTIPLY, etc.), although OPM Flow also supports these keywords as well.

The PYINPUT facility should be considered experimental as details of the OPM Flow - Python interface might change for future releases. In particular, the current implementation is quite minimal; however, future releases are expected to add more entry points in the simulator's deck class which can be used to manipulate the input deck as the data is loaded. As a user you are encouraged to come with wishes in this regard.

The PYINPUT facility is very powerful and allows for any piece of Python code to be included and run, including potentially malicious code. The important point is to scrutinize the Python code in between PYINPUT and PYEND in a deck you receive from other parties.

No.	Name	Description	Default
PYINPUT		PYINPUT declares the start of a PYINPUT Definition Section. This is then followed by any number Python commands.	Not Applicable
1-1	PYTHON	A series of standard Python commands with one line per command. The active Parser objects are accessible as context.parser and the active Deck object is available as context.deck.	
PYEND		PYEND declares the end of a PYINPUT Definition Section. The Python code between PYINPUT and PYEND is read and executed, and the simulator thenreturns to reading the normal simulation input deck.	

Notes:

1) There is no terminating "/" for this keyword, instead the PYEND keyword terminates the keyword.

Table 6.114: PYINPUT Keyword Description

The PYINPUT/PYEND set of keywords is a result of combining two programming languages, the interactive Python interpreter and OPM Flow's source code language C++. When combining two languages one extends and embeds one into the other. When extending Python with C++ the functionality implemented in C++ is made available to Python applications, when embedding Python in C++ one can call Python functions from within C++. The PYINPUT/PYEND set of keywords is based on embedding a Python interpreter in the C++ OPM Flow simulator, but the Python code actually runs as part of the PYINPUT keyword is based on wrapping C++ objects in Python, that is extending Python.

The Python code in between the PYINPUT and PYEND keywords are imported during processing of the input deck and as such this implies that basic Python syntax checking is performed during reading the Python script.

See also the PYACTION keyword in the SCHEDULE section which is also part of OPM Flow's Python scripting facility, that loads a standard Python script file that can be used to define a series of conditions and actions as the simulation proceeds through time.

Example

The example shows how to construct the DX variable in the GRID section and to add the resulting DX array as part of the input deck.

```
--
--       START OF PYINPUT SECTION
--
PYINPUT
#
# Import Numpy Model
#
import numpy as np
#
# Define DX and Get the Input Decks Unit Systems
#
dx = np.array([100.0, 100.0, 100.0, 100.0])
active_unit_system  = context.deck.active_unit_system()
default_unit_system = context.deck.default_unit_system()
#
# Set DX in the Input Deck
#
kw = context.DeckKeyword( context.parser['DX'], dx, active_unit_system,
default_unit_system )
context.deck.add(kw)

PYEND
```

The active Parser objects is accessible as context.parser and the active Deck object is available as context.deck.

6.3.182 QMOBIL ACTIVATE OR DEACTIVATE LGR END-POINT MOBILITY CORRECTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The QMOBIL keyword activates or deactivates the end-point mobility correction for Local Grid Refinements ("LGR"), for when LGRs have been activated for the input deck using the LGR keyword in the RUNSPEC section. QMOBIL should be placed in between the LGR definition keywords CARFIN, or RADIN (or RAFDIN4) and the ENDFIN keyword in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.183 RADFIN – DEFINE A RADIAL LOCAL GRID REFINEMENT WITH ONE COLUMN

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines a radial local grid refinement using one columns Local grid refinement is currently not supported by OFM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.184 RADFIN4 – DEFINE A RADIAL LOCAL GRID REFINEMENT WITH FOUR COLUMNS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines a radial local grid refinement using four columns. Local grid refinement is currently not supported by OFM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.185 REFINE – START THE DEFINITION OF A LOCAL GRID REFINEMENT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The REFINE keyword defines the start of a Cartesian or radial Local Grid Refinement ("LGR") definition that sets the properties of the selected LGR. The keyword is then followed by the property keywords associated with the section where the keyword is being invoked. For example, if the REFINE keyword is used in the GRID section then most of the keywords in that section can be used to set the grid properties for the LGR.

The ENDFIN keyword is used to terminate the LGR definition.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.186 RESVNUM – DEFINE RESERVOIR COORDINATE DATA SET

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The RESVNUM keyword is used to define the start of a reservoir coordinate data set and stipulates the reservoir number for the data set. The keyword is used in conjunction with the COORD keyword in the GRID section, that specifies a set of coordinate lines or pillars for a reservoir grid via an array. Note that the COORD keyword should immediately follow the RESVNUM keyword.

Although the keyword is processed by OPM Flow, the keyword is effectively ignored as only the default value of one is supported.

No.	Name	Description	Default
1	RESVNUM	A positive integer values that defines the reservoir coordinate data set, or the independent reservoir, for which the subsequent COORD data is to be associated with. RESVNUM should be less than or equal to NUMRES on the NUMRES keyword in the RUNSPEC section. OPM Flow currently only accepts a single data set, that is the default value of one.	1
Notes: 1) The keyword is terminated by a "/".			

Table 6.115: RESVNUM Keyword Description

See the NUMRES keyword in the RUNSPEC section that defines the number of reservoir grids (COORD data sets) that the simulator should process.

The facility is useful to combine two separate reservoir grids into one model in the simulator.

Example

```
--
--       NUMRES
--       NUMBER
RESVNUM
         1                                                                  /
--
-- SPECIFY VERTICAL COORDINATE LINES FOR A REGULAR 3 x 2 GRID
--(DX = 100 and DY = 200)
--
-- X1     Y1    Z1      X2     Y2    Z2
-- ---    ---   ----    ---    ---   ----
COORD
     0      0   1000      0      0   5000
   100      0   1000    100      0   5000
   200      0   1000    200      0   5000
   300      0   1000    300      0   5000
     0    200   1000      0    200   5000
   100    200   1000    100    200   5000
   200    200   1000    200    200   5000
   300    200   1000    300    200   5000
     0    400   1000      0    400   5000
   100    400   1000    100    400   5000
   200    400   1000    200    400   5000
   300    400   1000    300    400   5000
/
--
--       NUMRES
--       NUMBER
RESVNUM
         2                                                                  /
--
-- SPECIFY VERTICAL COORDINATE LINES FOR A REGULAR 3 x 2 GRID
--(DX = 100 and DY = 200)
--
-- X1     Y1    Z1      X2     Y2    Z2
-- ---    ---   ----    ---    ---   ----
COORD
     0      0   1000      0      0   5000
   100      0   1000    100      0   5000
   200      0   1000    200      0   5000
   300      0   1000    300      0   5000
     0    200   1000      0    200   5000
   100    200   1000    100    200   5000
   200    200   1000    200    200   5000
   300    200   1000    300    200   5000
     0    400   1000      0    400   5000
   100    400   1000    100    400   5000
   200    400   1000    200    400   5000
   300    400   1000    300    400   5000
/
```

6.3.187 ROCKFRAC - DEFINE THE ROCK VOLUME TO BULK VOLUME FRACTION FOR ALL THE CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ROCKFRAC defines the rock volume to bulk volume fraction for all the cells, The keyword can be used with all grid types. Rock volume of a grid block is calculated by multiply a cell's bulk volume by it's ROCKFRAC volume. A cell's rock volume is used in the Coal option to calculate the adsorbed gas in the rock (coal), as well as the Thermal and Temp options to calculate the energy is stored in the rock.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ROCKFRAC	ROCKFRAC is an array of real numbers greater than or equal to zero and less than or equal to one, that are assigned the rock volume to bulk volume fraction values for each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 200*0.850.			
		dimensionless	dimensionless	dimensionless	None
Notes: 1) Setting a cells ROCKFRAC value to zero will make the cell inactive, similar to setting the cells ACTNUM property to zero. 2) The keyword is terminated by a "/".					

Table 6.116: NTG Keyword Description

See also the PORO, PERMX, PERMY, PERMZ and NTG keywords to fully define a grid's properties.

Example

```
--
--       DEFINE GRID ROCKFRAC DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
ROCKFRAC
         100*1.000   100*0.850   100*0.500                                    /
```

The above example defines a constant ROCKFRAC of 1.00 for the first 100 cells, then 0.85 for the second 100 hundred cells, and finally 0.500 for the last 100 cell, for the 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.188 RPTGRID – DEFINE GRID SECTION REPORTING

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the data in the GRID section that is to be printed to the output print file in human readable format. The keyword has two distinct forms, the first of which consists of the keyword followed by a series of integers on the next line indicating the data to be printed (see the first example). This is the original formal in the commercial simulator and was subsequently superseded by the second format. The second format consists of the keyword followed by a series of character strings that indicate the data to be printed. In most cases the character string is the keyword used to load the data in the OPM Flow input deck, for example PORO for the porosity array. Its is anticipated that OPM Flow will eventually support the functionality of the second format only, the first format although recognized will be completely ignored.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description	Default
1	ALLNCC	Print all the non-neighbor connections.	N/A
2	COORD	Print the coordinate lines.	N/A
3	COORDYS	Print the coordinate systems.	N/A
4	DEPTH	Print grid cells center depths.	N/A
….		….	N/A

Notes:

1) The keyword is terminated by a "/".

Table 6.117: RPTGRID Keyword Description

Note

This keyword has the potential to produce very large print files that some text editors may have difficulty loading, coupled with the fact that reviewing the data in this format is very cumbersome.

A more efficient solution is to load the *.INIT file into OPM ResInsight to view the data graphically, this also has the benefit of being able to filter the grid based on I, J, K ranges and grid properties.

Examples

The first example shows the original format of this keyword; although the keyword and format are recognized by OPM Flow, the format is ignored and is unlikely to be implemented in in the simulator.

```
--
--       DEFINE GRID SECTION REPORT OPTION (ORIGINAL FORMAT)
-
RPTGRID
         1        2*0      1        3*1                                        /
```

The next example shows the second format of the keyword which may be supported in a future release of OPM Flow.

```
--       DEFINE GRID SECTION REPORT OPTIONS
--
RPTGRID
         DX       DY       DZ       DEPTH    PORO     PERMX                   /
```

6.3.189 RPTGRIDL – DEFINE GRID SECTION REPORTING FOR LGRS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the data in the GRID section that is to be printed to the output print file in human readable format for Local Grid Refinements ("LGRs"), for when LGRs have been activated for the input deck using the LGR keyword in the RUNSPEC section.

The keyword has two distinct forms, the first of which consists of the keyword followed by a series of integers on the next line indicating the data to be printed (see the first example). This is the original formal in the commercial simulator and was subsequently superseded by the second format. The second format consists of the keyword followed by a series of character strings that indicate the data to be printed. In most cases the character string is the keyword used to load the data in the OPM Flow input deck, for example PORO for the porosity array. Its is anticipated that OPM Flow will eventually support the functionality of the second format only, the first format although recognized will be completely ignored.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description	Default
1	ALLNCC	Print all the non-neighbor connections.	N/A
2	COORD	Print the coordinate lines.	N/A
3	COORDYS	Print the coordinate systems.	N/A
4	DEPTH	Print grid cells center depths.	N/A
….		….	N/A
24	ALLNNC	ALLNNC is a defined positive integer that specifies the type of Non-Neighbor Connections ("NNC") to be printed, and should be set to one of the follow: 1) To print the NNCs within the LGRs, and the connections between the local and host cells to the print file (*.PRT). 2) To print the NNCs within the LGRs, and the connections between the local and host cells to the print (*.PRT) and debug files (*.DBG). 3) Same as (2) but the data in the debug file (*.DBG) is written out in an alternative format.	N/A
….		….	N/A
57	EXTHOST	EXTHOSTS outputs host cells for Perpendicular Bisector ("PEBI")[128] and [129] LGRs.	
….		….	N/A

No.	Name	Description	Default
1)	The keyword is terminated by a "/".		

Table 6.118: RPTGRIDL Keyword Description

Note

This keyword has the potential to produce very large print files that some text editors may have difficulty loading, coupled with the fact that reviewing the data in this format is very cumbersome.

A more efficient solution is to load the *.INIT file into OPM ResInsight to view the data graphically, this also has the benefit of being able to filter the grid based on I, J, K ranges and grid properties.

Examples

The first example shows the original format of this keyword; although the keyword and format are recognized by OPM Flow, the format is ignored and is unlikely to be implemented in in the simulator.

```
--
--       DEFINE LGR GRID SECTION REPORT OPTION (ORIGINAL FORMAT)
-
RPTGRIDL
         1        2*0      1        3*1                                    /
```

The next example shows the second format of the keyword which may be supported in a future release of OPM Flow.

```
--       DEFINE LGR GRID SECTION REPORT OPTIONS
--
RPTGRIDL
         DX       DY       DZ       DEPTH    PORO     PERMX                  /
```

6.3.190 RPTINIT – DEFINE OUTPUT TO THE INIT FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the data in the GRID and EDIT sections that is to be written out to the INIT file (*.INIT or *.FINIT). The format consists of the keyword followed by a series of character strings that indicate the data to be written. In most cases the character string is the keyword used to load the data into the OPM Flow input deck, for example PORO for the porosity array in the GRID section. In addition, values either read or calculated by the simulator in the EDIT section can also be written to the INIT file. Again the keyword or property name is used as the mnemonic for the character string, for example the PORV, TRANX keywords etc. If the RPTINIT keyword is not used in the input deck then a default set of data array are written to the file, in this case the actual data written is dependent on the model's configuration and the options being used.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

6.3.191 RPTISOL – ACTIVATE ISOLATED RESERVOIR NUMBER REPORTING

Description

The RPTISOL keyword activates the isolated reservoir report that generates an array of isolated region numbers that is printed in the debug file (*.DBG). The main purpose of this facility is to use the generated array as input to the ISOLNUM keyword in the GRID section in conjunction with the Independent Reservoir Regions option. If the model can be divided into isolated reservoirs then the individual reservoirs may be solved independently, resulting in increased computational efficient, compared with solving the model as a whole.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--       ACTIVATE ISOLATED RESERVOIR NUMBER REPORTING
--
RPTISOL
```

The above example activates the isolated reservoir report that generates an array of isolated region numbers to the debug file (*.DBG).

6.3.192 SIGMA – DUAL POROSITY MATRIX TO FRACTURE SIGMA (ALL CELLS)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SIGMA keyword defines the dual porosity matrix to fracture transmissibility multiplier, sigma, that is applied to all cells, for when the Dual Porosity model has been activated by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section. Sigma (σ) takes into account the matrix-fracture interface area per unit volume and was defined by Kazemi et al[130] to be:

$$\sigma = 4\left(\frac{1}{l_x^2} + \frac{1}{l_y^2} + \frac{1}{l_z^2}\right) \tag{6.15}$$

Where lx, ly and lz are not the grid block dimensions in the model in the respective directions, but the dimensions of the blocks of the matrix material. In practice, σ is used as a tuning parameter in dual porosity runs to match reservoir and well performance.

See also the SIGMAV keyword in the GRID section that supplies the sigma values on an individual cells basis.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.193 SIGMAGD – DUAL POROSITY MATRIX TO FRACTURE SIGMA FOR GRAVITY DRAINAGE (ALL CELLS)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SIGMAGD keyword defines the dual porosity matrix to fracture transmissibility multiplier, sigma, that is applied to all cells, for when the Dual Porosity model has been activated by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section. In addition, the GRAVDR keyword in the RUNSPEC section should be used to enable the Gravity Drainage model for the run. Sigma (σ) takes into account the matrix-fracture interface area per unit volume and was defined by Kazemi et al[131] to be:

$$\sigma = 4\left(\frac{1}{l_x^2} + \frac{1}{l_y^2} + \frac{1}{l_z^2}\right) \tag{6.16}$$

Where lx, ly and lz are not the grid block dimensions in the model in the respective directions, but the dimensions of the blocks of the matrix material. In practice, σ is used as a tuning parameter in dual porosity runs to match reservoir and well performance.

Note that SIGMAGD keyword data is used for areas being swept by gas and the SIGMA keyword data is used when the area is being invaded by water. See also the SIGMAGDV keyword in the GRID section that supplies the sigma values on an individual cells basis

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[131] *Kazemi, H., Merrill JR., L. S., Porterfield, K. L., and Zeman, P. R. "Numerical Simulation of Water-Oil Flow in Naturally Fractured Reservoirs," paper SPE 5719, Society of Petroleum Engineers Journal (1976) 16, No. 6, 317-326.*

6.3.194 SIGMAGDV – DUAL POROSITY MATRIX TO FRACTURE SIGMA GRAVITY DRAINAGE (INDIVIDUAL CELLS)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SIGMAGD keyword defines the dual porosity matrix to fracture transmissibility multiplier, sigma, that is applied to individual cells, for when the Dual Porosity model has been activated by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section. In addition, the GRAVDR keyword in the RUNSPEC section should be used to enable the Gravity Drainage model for the run. Sigma (σ) takes into account the matrix-fracture interface area per unit volume and was defined by Kazemi et al[132] to be:

$$\sigma = 4\left(\frac{1}{l_x^2} + \frac{1}{l_y^2} + \frac{1}{l_z^2}\right) \tag{6.17}$$

Where lx, ly and lz are not the grid block dimensions in the model in the respective directions, but the dimensions of the blocks of the matrix material. In practice, σ is used as a tuning parameter in dual porosity runs to match reservoir and well performance.

Note that SIGMAGDV keyword data is used for areas being swept by gas and the SIGMA keyword data is used when the area is being invaded by water. See also the SIGMAGD keyword in the GRID section that supplies a constant sigma value for all cells.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[132] *Kazemi, H., Merrill JR., L. S., Porterfield, K. L., and Zeman, P. R. "Numerical Simulation of Water-Oil Flow in Naturally Fractured Reservoirs," paper SPE 5719, Society of Petroleum Engineers Journal (1976) 16, No. 6, 317-326.*

6.3.195 SIGMAV – DUAL POROSITY MATRIX TO FRACTURE SIGMA (INDIVIDUAL CELLS)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SIGMAV keyword defines a dual porosity matrix to fracture multiplier, sigma, that is applied to individual cells, for when the Dual Porosity model has been invoked by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section. Sigma (σ) takes into account the matrix-fracture interface area per unit volume and was defined by Kazemi et al[133] to be:

$$\sigma = 4\left(\frac{1}{l_x^2} + \frac{1}{l_y^2} + \frac{1}{l_z^2}\right) \tag{6.18}$$

Where lx, ly and lz are not the grid block dimensions in the model in the respective directions, but the dimensions of the blocks of the matrix material. In practice, σ is used as a tuning parameter in dual porosity runs to match reservoir and well performance.

See also the SIGMA keyword in the GRID section that supplies a constant sigma to all cells.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[133] *Kazemi, H., Merrill JR., L. S., Porterfield, K. L., and Zeman, P. R. "Numerical Simulation of Water-Oil Flow in Naturally Fractured Reservoirs," paper SPE 5719, Society of Petroleum Engineers Journal (1976) 16, No. 6, 317-326.*

6.3.196 SKIP – ACTIVATE SKIPPING OF ALL KEYWORDS AND INPUT DATA

The SKIP keyword turns on skipping of keywords until the ENDSKIP activation keyword is encountered. All keywords and between the SKIP and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP – Activate Skipping of All Keywords and Input Data* in the GLOBAL section for a full description.

6.3.197 SKIP100 – ACTIVATE SKIPPING OF BLACK-OIL KEYWORDS AND INPUT DATA

This keyword turns on skipping of black-oil keywords until the ENDSKIP activation keyword is encountered. All black-oil keywords between the SKIP100 and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP100 – Activate Skipping of Black-Oil Keywords and Input Data* in the GLOBAL section for a full description.

6.3.198 SKIP300 – ACTIVATE SKIPPING OF "COMPOSITIONAL" KEYWORDS AND INPUT DATA

Turns on skipping of "compositional" keywords until the ENDSKIP activation keyword is encountered. All "compositional" keywords between the SKIP300 and ENDSKIP keywords are ignored by OPM Flow.

See *Error: Reference source not found* in the GLOBAL section for a full description.

6.3.199 SMULTX - MULTIPLY CELL TRANSMISSIBILITY IN THE +X DIRECTION (AUTO-REFINEMENT)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SMULTX multiples the transmissibility between two cell faces in the +X direction between cells in a host base grid and the connecting auto-refined grid cells, via an array, that is the keyword sets the transmissibility multiplier of block (Ihost, Jhost, Khost) in the host base grid, multiplies the transmissibility all the cells (Iauto, Jauto, Kauto) and (I+Iauto, Jauto, Kauto) in the auto-refinement grid. The Auto Refinement option must be enabled to use this keyword via the AUTOREF keyword in the RUNSPEC section.

An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the SMULTX keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	SMULTX+	SMULTX+ is an array of real positive numbers assigning the transmissibility multipliers in the +X direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.119: SMULTX Keyword Description

See also the MULTX, MULTY and MULTZ keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   3                          / DEFINE BOX AREA
--
--       SET SMULTX+ TRANSMISSIBILITY MULTIPLIERS
--
SMULTX
         18*0.300                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.3 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.200 SMULTY - MULTIPLY CELL TRANSMISSIBILITY IN THE +Y DIRECTION (AUTO-REFINEMENT)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SMULTY multiples the transmissibility between two cell faces in the +Y direction between cells in a host base grid and the connecting auto-refined grid cells, via an array, that is the keyword sets the transmissibility multiplier of block (Ihost, Jhost, Khost) in the host base grid, multiplies the transmissibility all the cells (Iauto, Jauto, Kauto) and (Iauto, J+1auto, Kauto) in the auto-refinement grid. The Auto Refinement option must be enabled to use this keyword via the AUTOREF keyword in the RUNSPEC section.

An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the SMULTY keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	SMULTY+	SMULTY+ is an array of real positive numbers assigning the transmissibility multipliers in the +X direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.120: SMULTY Keyword Description

See also the MULTX, MULTY and MULTZ keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   3                          / DEFINE BOX AREA
--
--       SET SMULTY+ TRANSMISSIBILITY MULTIPLIERS
--
SMULTY
         18*0.300                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.3 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.201 SMULTZ - MULTIPLY CELL TRANSMISSIBILITY IN THE +Z DIRECTION (AUTO-REFINEMENT)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SMULTZ multiples the transmissibility between two cell faces in the +Z direction between cells in a host base grid and the connecting auto-refined grid cells, via an array, that is the keyword sets the transmissibility multiplier of block (Ihost, Jhost, Khost) in the host base grid, multiplies the transmissibility all the cells (Iauto, Jauto, Kauto) and (Iauto, Jauto, K+1auto) in the auto-refinement grid. The Auto Refinement option must be enabled to use this keyword via the AUTOREF keyword in the RUNSPEC section.

An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the SMULTZ keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	SMULTZ+	SMULTZ+ is an array of real positive numbers assigning the transmissibility multipliers in the +X direction to each cell face in the model. Repeat counts may be used, for example 20*100.0.	1.0

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.121: SMULTX Keyword Description

See also the MULTX, MULTY and MULTZ keywords for scaling transmissible between grid cells.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   3                          / DEFINE BOX AREA
--
--       SET SMULTZ+ TRANSMISSIBILITY MULTIPLIERS
--
SMULTZ
         18*0.300                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The above example defines a 0.3 scaling multiplier for the 18 cells defined by the preceding BOX statement. The ENDBOX keyword resets the input box to the full grid.

6.3.202 SOLVDIRS – DEFINE LINEAR SOLVER PRINCIPAL DIRECTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SOLVDIRS keyword defines the linear solver principal directions, which should be set to XY, XZ, YX, YX, ZX, or ZY. The default direction is based on the direction of the highest transmissibility and SOLVDIRS allows for over writing the default direction for when linear convergence of the equations are problematic.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

See section *2.2 Running OPM Flow 2023-10 From The Command Line* on how to invoke various numerical schemes via the OPM Flow command line interface.

6.3.203 SOLVNUM – DEFINE PEBI GRID CORRESPONDENCE TO SOLVER ORDER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SOLVNUM defines the unstructured Perpendicular Bisector ("PEBI")[134] and [135] grid correspondence to the nested factorization solver order, for when the grid has been entered as a PEBI list. This keyword is generated by an external pre-processing program for generating simulation grids.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[134] *Heinemann, Z.E. and Brand, C.W. 1988. Gridding Techniques in Reservoir Simulation. Proc., First Intl. Forum on Reservoir Simulation, Alpbach, Austria, 339.*

[135] *Heinemann, Z.E., Brand, C.W., Munka, M. et al. 1991. Modeling Reservoir Geometry With Irregular Grids. SPE Res Eng 6 (2): 225–232. SPE-18412-PA. http://dx.doi.org/10.2118/18412-PA*

6.3.204 SPECGRID- DEFINE THE DIMENSIONS OF A CORNER-POINT GRID

Description

SPECGRID defines the dimensions of corner-point and radial grids in the x, y, and z directions as well as the number of reservoirs, where each reservoir has its own set of corner-point geometry data.

The keyword can only be used with Irregular Corner-Point Grids and Radial Grids.

No.	Name	Description	Default
1	NDIVIX	A positive integer value that defines the number of cells in the X or R direction	1
2	NDIVIY	A positive integer value that defines the number of cells in the Y or THETA direction	1
3	NDIVZ	A positive integer value that defines the number of cells in the Z direction	1
4	NUMRES	A positive integer values that defines number of coordinate data sets, or independent reservoirs in the model. OPM Flow currently only accepts a single data set, that is the default value of one.	1
5	TYPE	A character string set to either T of F that defines the type of grid to be defined by subsequent keywords: 1) T = Radial grid with radial coordinates 2) F = Cartesian grid Only the default option F is supported by OPM Flow.	F
Notes: 1) The dimensions are also entered on the DIMENS keyword in the RUNSPEC section and the two sets of numbers should be consistent. 2) The keyword is terminated by a "/".			

Table 6.122: SPECGRID Keyword Description

See also the COORD, COORDSYS and ZCORN keywords to fully define an Irregular Corner-Point Grid.

Example

```
--
--        MAX     MAX     MAX     MAX     GRID
--        NDIVIX  NDIVIY  NDIVIZ  NUMRES  TYPE
SPECGRID
          46      112     22      1       F                                  /
```

The above example defines a 46 x 112 x 22 grid with one set of irregular corner-point data.

6.3.205 THCGAS – DEFINE GAS PHASE THERMAL CONDUCTIVITY FOR ALL CELLS

Description

The THCGAS keyword defines the gas phase thermal conductivity for when the thermal calculation is activated by the THERMAL keyword in the RUNSPEC section, and should be used in conjunction with THCROCK keyword in the GRID section.

This keyword can only be used if the thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	THCGAS	THCGAS is an array of real positive numbers that define the thermal conductivity of the gas phase in each grid block. Repeat counts may be used, for example 3000*20.0			
		Btu/ft/day/°R	kJ/m/day/K	J/cm/hr/K	None
Notes: 1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement. 2) The keyword is terminated by a "/".					

Table 6.123: THCGAS Keyword Description

Note that there two ways to define the rock and in situ fluids thermal conductivity:

1) Either by using the THCONR keyword to define the combined rock and fluid conductivity, and optionally the THCONSF keyword in the GRID section, or
2) by specifying the rock and fluid conductivities individually using the THCROCK, THCOIL, THCGAS, and THCWATER keywords in the GRID section.

Hence, the THCROCK and THCONR keywords are mutually exclusive.

Here, the THCGAS keyword is used in conjunction with the other thermal conductivity arrays to calculate the porosity weighted thermal conductivity of a grid block using:

$$\text{Average Thermal Conductivity} = \frac{PORO \times (THCOIL + THCGAS + THCWATER + THCSOLID)}{\text{NUMBER OF PHASES IN THE MODEL}} \times (1 - PORO) \times THCROCK \quad (6.19)$$

See also the THCOIL, and THCWATER, and THCROCK keywords in the GRID section. The commercial compositional simulator's THCSOLID keyword is not supported or required by OPM Flow.

Example

```
--
--       DEFINE GRID BLOCK GAS PHASE THERMAL CONDUCTIVITY
-        FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
THCGAS
         300*20.0                                                    /
```

The above example defines the gas phase thermal conductivity of 20.0 for each cell in the 300 grid block model as defined by the DIMENS keyword in the RUNSPEC section.

6.3.206 THCOIL – DEFINE OIL PHASE THERMAL CONDUCTIVITY FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The THCOIL keyword defines the oil phase thermal conductivity for when the thermal calculation is activated by the THERMAL keyword in the RUNSPEC section, and should be used in conjunction with THCROCK keyword in the GRID section.

This keyword can only be used if the thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	THCOIL	THCOIL is an array of real positive numbers that define the thermal conductivity of the oil phase in each grid block. Repeat counts may be used, for example 3000*20.0			
		Btu/ft/day/°R	kJ/m/day/K	J/cm/hr/K	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 6.124: THCOIL Keyword Description

Note that there two ways to define the rock and in situ fluids thermal conductivity:

1) Either by using the THCONR keyword to define the combined rock and fluid conductivity, and optionally the THCONSF keyword in the GRID section, or
2) by specifying the rock and fluid conductivities individually using the THCROCK, THCOIL, THCGAS, and THCWATER keywords in the GRID section.

Hence, the THCROCK and THCONR keywords are mutually exclusive.

Here, the THCOIL keyword is used in conjunction with the other thermal conductivity arrays to calculate the porosity weighted thermal conductivity of a grid block using:

$$\text{Average Thermal Conductivity} = \frac{PORO \times (THCOIL + THCGAS + THCWATER + THCSOLID)}{\text{NUMBER OF PHASES IN THE MODEL}} \times (1 - \text{PORO}) \times \text{THCROCK} \quad (6.20)$$

See also the THCGAS, and THCWATER, and THCROCK keywords in the GRID section. The commercial compositional simulator's THCSOLID keyword is not supported or required by OPM Flow.

Example

```
--
--       DEFINE GRID BLOCK OIL PHASE THERMAL CONDUCTIVITY
-        FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
THCOIL
         300*20.0                                                    /
```

The above example defines the oil phase thermal conductivity of 20.0 for each cell in the 300 grid block model, as defined by the DIMENS keyword in the RUNSPEC section.

6.3.207 THCONR – DEFINE ROCK AND FLUID THERMAL CONDUCTIVITY FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The THCONR keyword defines the reservoir rock plus fluid thermal conductivity for all cells for when the thermal calculation is activated by the THERMAL keywords in the RUNSPEC section.

This keyword can only be used if the thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	THCONR	THCONR is an array of real positive numbers that define the combined rock and fluid conductivity of a grid block. Repeat counts may be used, for example 3000*25.0			
		Btu/ft/day/°R	kJ/m/day/K	J/cm/hr/K	None
Notes: 1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement. 2) The keyword is terminated by a "/".					

Table 6.125: THCONR Keyword Description

Note that there two ways to define the rock and in situ fluids thermal conductivity:

1) Either by using the THCONR keyword to define the combined rock and fluid conductivity, and optionally the THCONSF keyword in the GRID section, or
2) by specifying the rock and fluid conductivities individually using the THCROCK, THCOIL, THCGAS, and THCWATER keywords in the GRID section.

Hence, the THCROCK and THCONR keywords are mutually exclusive.

Example

```
--
--       DEFINE GRID BLOCK ROCK-FLUID THERMAL CONDUCTIVITY
--       FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
THCONR
         300*25.0                                                    /
```

The above example defines the combined rock and fluid thermal conductivity of 25.0 for each cell in the 300 grid block model, as defined by the DIMENS keyword in the RUNSPEC section.

6.3.208 THCONSF – DEFINE GAS SATURATION DEPENDENT THERMAL CONDUCTIVITY SCALING FACTOR FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The THCONSF keyword defines a gas saturation dependent scaling factor to the fluid and reservoir rock thermal conductivities entered via the THCONR keyword in the GRID section, for when the thermal calculation is activated by the THERMAL keyword in the RUNSPEC.

This keyword can only be used if the thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	THCONSF	THCONSF is an array of real positive numbers, greater than zero and less than or equal to one, that define the gas saturation dependent scaling factor that is applied to the THCONR data, entered via the THCONR keyword, to adjust the thermal conductivity of the reservoir cells in each grid block. Repeat counts may be used, for example 3000*0.15			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.126: THCROCK Keyword Description

Note that there two ways to define the rock and in situ fluids thermal conductivity:

1) Either by using the THCONR keyword to define the combined rock and fluid conductivity, and optionally the THCONSF keyword in the GRID section, or

2) by specifying the rock and fluid conductivities individually using the THCROCK, THCOIL, THCGAS, and THCWATER keywords in the GRID section.

Hence, the THCROCK and THCONR keywords are mutually exclusive.

Here, the THCONSF keyword defines a scaling factor which is a function of the gas saturation that scales a cells total thermal conductivity (reservoir fluids plus reservoir rock) entered via the THCONR keyword in the GRID section. This combination of keywords, THCONSF and THCONR implies that the oil and water phase thermal conductivities are saturation independent with respect to the liquid phase, and that only the gas saturation influences a cell's thermal conductivity as entered via the THCONR keyword.

Thus, THCONSF scales the THCONR values via a multiplier Ω, by:

$$\Omega_{i,j,k} = \left(1 - \text{THCONSF x Gas Saturation}\right)_{i,j,k} \quad \textbf{(6.21)}$$

See also the THCGAS, THCOIL, THCWATER and THROCK keywords in the GRID section, for an alternative way to enter the thermal conductivity properties. However, the THCONSF keyword cannot be used with the THCGAS, THCOIL, THCWATER and THCROCK keywords. Secondly, the commercial compositional simulator's THCSOLID keyword is not supported or required by OPM Flow.

Example

```
--
--       DEFINE GRID SGAS DEPENDENT SCALING FACTOR FOR THE THCONR ARRAY
--       FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--       (OPM FLOW THERMAL OPTION ONLY)
--
THCONSF
         300*0.12                                                              /
```

The above example defines the gas saturation thermal conductivity scaling factor to be applied to the THCONR to be 0.12 for all 300 cells in the model, as defined by the DIMENS keyword in the RUNSPEC section.

6.3.209 THCROCK – DEFINE RESERVOIR ROCK THERMAL CONDUCTIVITY FOR ALL CELLS

Description

The THCROCK keyword defines the reservoir rock thermal conductivity for when the thermal calculation is activated by the THERMAL keyword in the RUNSPEC section.

This keyword can only be used if the thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	THCROCK	THCROCK is an array of real positive numbers that define the thermal conductivity of the reservoir rock in each grid block. Repeat counts may be used, for example 3000*20.0			
		Btu/ft/day/°R	kJ/m/day/K	J/cm/hr/K	None
Notes: 1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement. 2) The keyword is terminated by a "/".					

Table 6.127: THCROCK Keyword Description

Note that there two ways to define the rock and in situ fluids thermal conductivity:

1) Either by using the THCONR keyword to define the combined rock and fluid conductivity, and optionally the THCONSF keyword in the GRID section, or
2) by specifying the rock and fluid conductivities individually using the THCROCK, THCOIL, THCGAS, and THCWATER keywords in the GRID section.

Hence, the THCROCK and THCONR keywords are mutually exclusive.

Here, the THCROCK keyword is used in conjunction with the other thermal conductivity arrays to calculate the porosity weighted thermal conductivity of a grid block using:

$$\text{Average Thermal Conductivity} = \frac{PORO \times (THCOIL + THCGAS + THCWATER + THCSOLID)}{\text{NUMBER OF PHASES IN THE MODEL}} \times (1 - PORO) \times THCROCK \quad (6.22)$$

See also the THCOIL, and THCGAS, and THCWATER keywords in the GRID section. The commercial compositional simulator's THCSOLID keyword is not supported or required by OPM Flow.

Example

```
--
--       DEFINE GRID BLOCK RESERVOIR ROCK THERMAL CONDUCTIVITY
-        FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
THCROCK
         300*20.0                                                    /
```

The above example defines the reservoir rock thermal conductivity of 20.0 for each cell in the 300 grid block model, as defined by the DIMENS keyword in the RUNSPEC section.

6.3.210 THCWATER – DEFINE WATER PHASE THERMAL CONDUCTIVITY FOR ALL CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The THCWATER keyword defines the water phase thermal conductivity for when the thermal calculation is activated by the THERMAL keyword in the RUNSPEC section, and should be used in conjunction with THCROCK keyword in the GRID section.

This keyword can only be used if the thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	THCWATER	THCWATER is an array of real positive numbers that define the thermal conductivity of the water phase in each grid block. Repeat counts may be used, for example 3000*20.0			
		Btu/ft/day/°R	kJ/m/day/K	J/cm/hr/K	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 6.128: THCWATER Keyword Description

Note that there two ways to define the rock and in situ fluids thermal conductivity:

1) Either by using the THCONR keyword to define the combined rock and fluid conductivity, and optionally the THCONSF keyword in the GRID section, or

2) by specifying the rock and fluid conductivities individually using the THCROCK, THCOIL, THCGAS, and THCWATER keywords in the GRID section.

Hence, the THCROCK and THCONR keywords are mutually exclusive.

Here, the THCWATER keyword is used in conjunction with the other thermal conductivity arrays to calculate the porosity weighted thermal conductivity of a grid block using:

$$\text{Average Thermal Conductivity} = \frac{PORO \times (THCOIL + THCGAS + THCWATER + THCSOLID)}{\text{NUMBER OF PHASES IN THE MODEL}} \times (1 - PORO) \times THCROCK \quad (6.23)$$

See also the THCGAS, and THCOIL, and THCROCK keywords in the GRID section. The commercial compositional simulator's THCSOLID keyword is not supported or required by OPM Flow

Example

```
--
--       DEFINE GRID BLOCK WATER PHASE THERMAL CONDUCTIVITY
-        FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
THCWATER
         300*20.0                                                    /
```

The above example defines the water phase thermal conductivity of 20.0 for each cell in the 300 grid block model, as defined by the DIMENS keyword in the RUNSPEC section.

6.3.211 THPRESFT - DEFINE FAULT THRESHOLD PRESSURES

Description

The THPRESFT keyword defines a fault threshold pressures that prevents fluid flow from occurring across the fault plane until the threshold pressure is exceeded, for when the threshold pressure option has been activated via the THRPRES variable on the EQLOPTS keyword in the RUNSPEC section.

Each row entry in the THPRESFT keyword defines a fault threshold pressure.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	FLTNAME	FLTNAME is a character string enclosed in quotes with a maximum length of eight characters, that defines the name of the fault. FLTNAME must have been previously defined using the FAULTS keyword in the GROD section, otherwise an error will occur.			None
2	PRESS	PRESS is a single positive real value that defines the threshold pressure for the fault (FLTNAME). If PRESS is defaulted then the simulator will set the threshold pressure to zero, that is the fault is open to flow along the fault plane.			
		psia	barsa	atma	0
Notes: 1) If there are multiple entries for FLTNAME only the last entry is applied. 2) Each record is terminated by a "/" and the keyword should be terminated by a "/".					

Table 6.129: THPRESFT Keyword Description

See also the FAULTS keyword in the GRID section that is used to created named faults. Normally this fault data is automatically generated by pre-processing software that generates the static model.

Example

The example below defines two fault traces, 'M_WEST' and 'BC' fault having threshold pressures of 1000.0 and 2000 psis respectively.

```
--
--        DEFINE FAULTS IN THE GRID GEOMETRY
--
--        FAULT        ------------ FAULT TRACE -------------
--        NAME          I1   I2    J1   J2    K1   K2    FACE
FAULTS
          'M_WEST'       5    5     3    3     1    22   'X'   /
          'M_WEST'       5    5     4    4     1    22   'X'   /

6.3.212 TOPS - DEFINE THE DEPTH AT THE CENTER OF THE TOP FACE FOR EACH CELL

Description

TOPS defines the depth of the top face of each cell in the model.

It can only be used with the Cartesian Regular Grid or Radial Grid models.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TOPS	TOPS is an array of real numbers defining the depth at the top face of each cell in the model. One can either just enter the TOPS for the first layer only based on NX x NY entries and OPM Flow will calculate the remaining TOPS based on either DZ or DZV. Alternatively NX x NY x NZ TOPS may be entered for each cell in the model. See the DIMENS keyword in the RUNSPEC section for the definition of NX, NY and NZ. Repeat counts may be used, for example 10*5201.0.			
		feet	m	cm	None
Notes: 1) The keyword is terminated by a "/".					

Table 6.130: TOPS Keyword Description

See also the DEPTHS keyword to define the structural depth for the cells.

Examples

The example below defines the TOPS of the cells for each cell for NX = 5, NY = 5 and NZ = 3 model, as well as the X and Y direction cells sizes.

```
--
--       DEFINE GRID BLOCK TOPS FOR THE TOP LAYER (NX=5, NY=5, and NZ=3)
--
TOPS
         25*3100  25*3105  25*3110                                          /
--
--       DEFINE GRID BLOCK X DIRECTION CELL SIZE (BASED ON NX = 5)
--
DXV
         5*100                                                            /
--
--       DEFINE GRID BLOCK X DIRECTION CELL SIZE (BASED ON NY = 5)
--
DYV
         5*100                                                            /
```

A second example is shown on the following page.

This example defines the same grid as before but with the TOPS keyword only defining the top layer and DZV keyword defining the cells thickness.

```
--
--       DEFINE GRID BLOCK TOPS FOR THE TOP LAYER (NX = 5, NY = 5, NZ = 3)
--
TOPS
         25*3100                                                              /
--
--       DEFINE GRID BLOCK Z DIRECTION CELL SIZE (BASED ON NZ = 3)
--
DZV
         3*5.0                                                                /
--
--       DEFINE GRID BLOCK X DIRECTION CELL SIZE (BASED ON NX = 5)
--
DXV
         5*100                                                                /
--
--       DEFINE GRID BLOCK Y DIRECTION CELL SIZE (BASED ON NY = 5)
--
DYV
         5*100                                                                /
```

6.3.213 TRANGL – DEFINE NON-NEIGHBOR CONNECTIONS BETWEEN GLOBAL AND LGR CELLS MANUALLY

Description

TRANGL enables Non-Neighbor Connections ("NNC") between the global cells and the Local Grid Refinement ("LGR") cells to be manually specified, as oppose to the simulator calculating the transmissibilities. The LGR keyword in the RUNSPEC section should be utilized to define the presence of LGRs in the model and to define various LGR dimension parameters.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	I1	A positive integer that defines the LGR grid block in the I-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NX on the CARFIN keyword in the GRID section.			None
2	J1	A positive integer that defines the LGR grid block in the J-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NY on the CARFIN keyword in the GRID section.			None
3	K1	A positive integer that defines the LGR grid block in the K-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NZ on the CARFIN keyword in the GRID section.			None
4	I2	A positive integer that defines the GLOBAL grid block in the I-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NX on the DIMENS keyword in the RUNSPEC section.			None
5	J2	A positive integer that defines the GLOBAL grid block in the J-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NY on the DIMENS keyword in the RUNSPEC section.			None
6	K2	A positive integer that defines the GLOBAL grid block in the K-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NZ on the DIMENS keyword in the RUNSPEC section.			None
7	TRANSNNC	TRANSNNC is a positive real number greater than or equal to zero that defines the transmissibility between the GLOBAL grid block (I1, J1, K1) and the LGR grid block (I2, J2, K2). The default value of zero sets the transmissibility between the two cells to zero.			
		cP.rb/day/psia	cP.rm^3/day/bars	cP.rcc/hr/atm	0.0

Notes:

1) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 6.131: TRANGL Keyword Description

Example

```
--
--       MANUALLY DEFINE LGR-GLOBAL GRID NON-NEIGHBOR CONNECTIONS
--
--       ----LGR-----   ---GLOBAL----   -- TRANSNCC --
--       I1   J1   K1    I2   J2   K2
TRANGL
         1    1    1     1    1    2        0.2500     /
         1    1    2     1    1    3        0.2500     /
         1    1    3     1    1    4        0.2500     /
/
```

The above example defines the transmissibility between LGR cell (1, 1, 1) and global cell (1, 1, 2), LGR cell (1, 1, 2) and global cell (1, 1, 3) and finally between LGR cell (1, 1, 3) and global cell (1, 1, 4) to be 0.2500.

6.3.214 USEFLUX – ACTIVATE FLUX BOUNDARY MODEL AND DEFINE FLUX FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The USEFLUX keyword activates the Flux Boundary model and defines the name of the FLUX file. Only grid blocks that have been declared by the FLUXREG keyword in the GRID section to be in an active flux region, are active for the run.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.215 USENOFLO – ACTIVATE FLUX BOUNDARY MODEL WITHOUT A FLUX FILE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The USENOFLUX keyword activates the Flux Boundary model without a FLUX file. The USEFLUX keyword should still be in the input deck, but in this case the FLUX filename is ignored. The option is useful when the no-flow boundary condition is a reasonable assumption and avoids the pre-cursor run used to generate the FLUX file via the DUMPFLUX keyword in the GRID section. Only grid blocks that have been declared by the FLUXREG keyword in the GRID section to be in an active flux region, are active for the run.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE FLUX BOUNDARY MODEL WITHOUT A FLUX FILE
--
USEFLUX
/

USENOFLO
```

The above example activates the Flux Boundary model without a FLUX file.

6.3.216 VEDEBUG – VERTICAL EQUILIBRIUM DEBUG DATA OUTPUT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the debug Vertical Equilibrium ("VE") data to be written to the debug file (*.DBG), for when the VE model has been activated by the VE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.217 VEFIN – ACTIVATE VERTICAL EQUILIBRIUM MODEL (LGR)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

If the VE keyword in the RUNSPEC section has been used to activate the Vertical Equilibrium ("VE") model for the global grid, then the VEFIN keyword may used to set various options for the Local Grid Refinements ("LGR"). The LGR keyword in the RUNSPEC section should be activated to indicate the presence of LGRs and the keyword VEFIN should be placed in between the CARFIN and ENDFIN keywords in the GRID section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

6.3.218 WARN – ACTIVATE WARNING MESSAGES

Turns on warning messages to be printed to the print file (*.PRT); note that this keyword is activated by default and can subsequently be switched off by the NOWARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN. OPM Flow always prints error messages.

See *WARN – Activate Warning Messages* in the GLOBAL section for a full description.

6.3.219 ZCORN – DEFINE THE DEPTH OF EACH CORNER-POINT OF A GRID BLOCK

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ZCORN defines the depth of each corner point of a grid block on the pillars defining the reservoir grid. A total of 8 x NX x NY x NZ values are needed to fully define all the depths in the model. The depths specifying the top of the first layer are entered first with one point for each pillar for each grid block. The points are entered with the X axis cycling fastest. Next come the depths of the bottom of the first layer. The top of layer two follows etc.

The keyword can be only used be used with Irregular Corner-Point Grids.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ZCORN	An array of depths with 8 depths for each cell, for a total of 8 x Nx x NY x NZ entries			
		feet	metres	cm	None

Notes:

1) Regular Cartesian and Radial grid keywords cannot be used with this keyword, that is: DR, DRV, DTHETA, DTHETAV, DX, DXV, DY, DYV, DZ, INRAD, and TOPS.

2) The keyword is terminated by a "/".

Table 6.132: ZCORN Keyword Description

See also the SPECGRID, COORD and COORDSYS keywords to fully define an Irregular Corner-Point Grid.

Example

```
--
--       SPECIFY CORNER-POINT DEPTHS FOR A 3 x 2 x 2 GRID,
--       WITH CONSTANT SLOPE IN THE X AND Y DIRECTIONS
--       SUCH THAT ALL CORNER POINTS OF NEIGHBOURING BLOCKS ALIGN
ZCORN
--
--                    top of layer 1
--
         1450   1500   1500   1550   1550   1600
         1500   1550   1550   1600   1600   1650
         1500   1550   1550   1600   1600   1650
         1550   1600   1600   1650   1650   1700
--
--                     bottom of layer 1
--
         1460   1510   1510   1560   1560   1610
         1510   1560   1560   1610   1610   1660
         1510   1560   1560   1610   1610   1660
         1560   1610   1610   1660   1660   1710
--
--                     top of layer 2
--
         1460   1510   1510   1560   1560   1610
         1510   1560   1560   1610   1610   1660
```

```
          1510   1560   1560   1610   1610   1660
          1560   1610   1610   1660   1660   1710
--
--                    bottom of layer 2
--
          1470   1520   1520   1570   1570   1620
          1520   1570   1570   1620   1620   1670
          1520   1570   1570   1620   1620   1670
          1570   1620   1620   1670   1670   1720
/
```

The above example defines depths of the vertical coordinate lines for a regular 3 by 2 by 2 grid with a constant slope in the x and y directions such that all the corner points of neighboring blocks are aligned.

CHAPTER 7: EDIT SECTION

7.1 INTRODUCTION

This section enables user defined changes to be applied after OPM Flow has processed the data in the GRID section, that is the resulting pore volume (PORV) and transmissibility arrays (TRANX, TRANY and TRANX). The entered primary static arrays (PORO, PERMX etc.) in the GRID section are no longer available and all modifications are applied to the pore volume and transmissibility arrays.

Historically the intention of this section was allow for the editing of the processed data; however, the features available in this section have, through time, migrated to the GRID section. For example the array operator keywords like ADD, COPY, MULTIPLY, etc. are available in the GRID section and thus enabling editing of the primary static arrays (PORO, PERMX etc.). This increased in capability in the GRID section has therefore made the EDIT section some what redundant.

Nevertheless the section is sometimes used by users to incorporate history matching parameter changes and by static earth modeling software packages to import directly the pore volumes and transmissibilities calculated in the static model directly into the numerical model via the EDIT section. Although the latter work flow is not very common.

7.2 DATA REQUIREMENTS

As the primary purpose of this section is to modify the simulator's calculated pore volumes and transmissibilities, then the properties used to define these arrays must have been fully defined in the GRID section. The arrays available for modification in the EDIT section are listed in Table 7.1 together with the associated GRID arrays used to generate the EDIT property array.

Cartesian And Irregular Corner-Point Grids Keywords		Radial Grid Keywords	
GRID	**EDIT**	**GRID**	**EDIT**
TOPS	DEPTH	TOPS	DEPTH
DX	PORV	DR	PORV
DY		THETA	
DZ		DZ	
DZNET		DZNET	
PORO		PORO	
NTG		NTG	
PERMX	TRANX	PERMR	TRANR
MULTX		MULTR	
PERMY	TRANY	PERMTHT	TRANTHT
MULTY		MULTTHT	
PERMZ	TRANZ	PERMZ	TRANZ
MULTZ		MULTZ	

Notes:

1) Currently Radial Grids have not been implemented in OPM Flow.
2) The GRID property association to the EDIT property is only indicative as several variables, DZNET and NTG for example, are also used in the transmissibility calculations.

Table 7.1: EDIT Section Arrays Available for Modification

An example pore volume array (PORV property) from the Volve[136] field is shown in Figure 7.1 and Figure 7.2 illustrates the model's transmissibility in the x-direction (TRANX).

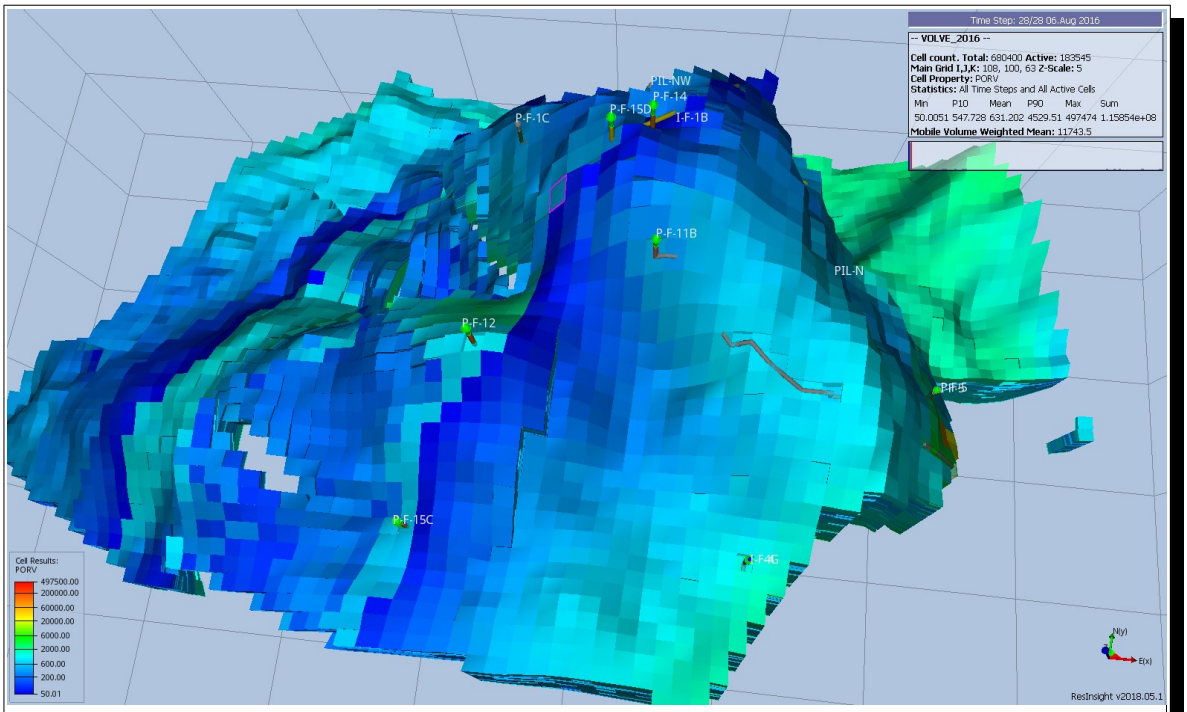

Figure 7.1: Volve Full Field Model PORV Array

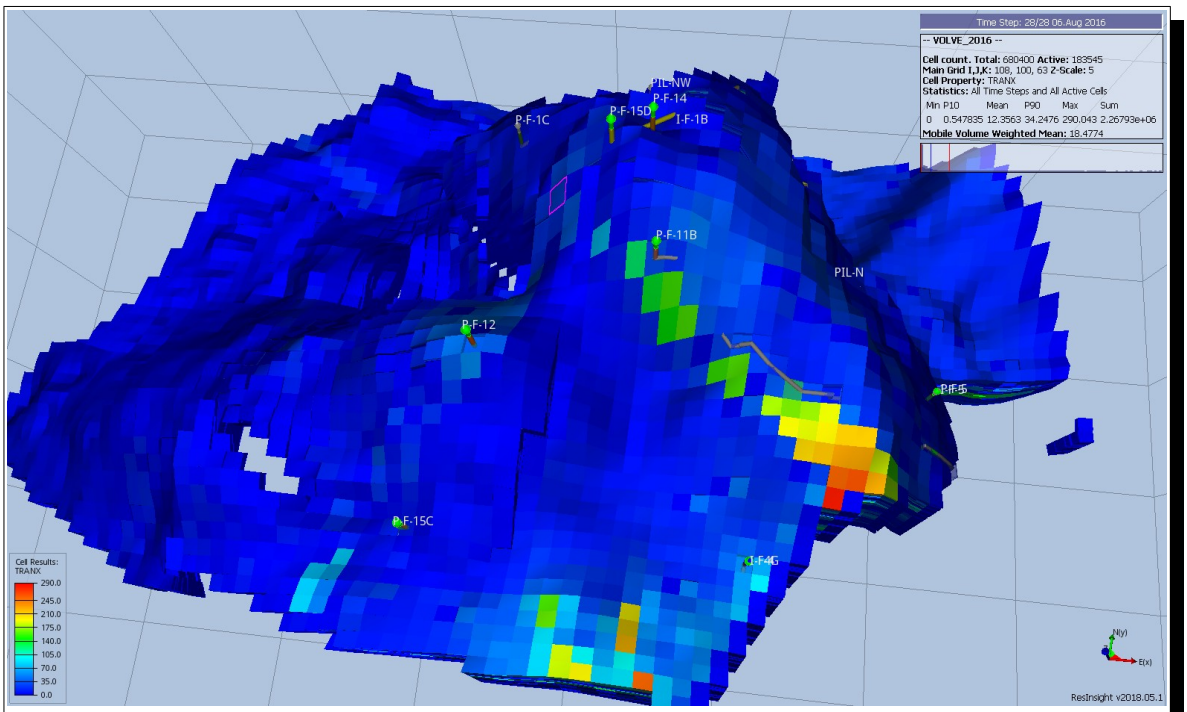

Figure 7.2: Volve Full Field Model TRANX Array

[136] *The Volve Data was approved for data sharing in 2018 by the initiative of the last Operating company, Equinor and approved by the license partners ExxonMobil E&P Norway AS and Bayerngas Norge AS in the end of 2017.*

7.3 KEYWORD DEFINITIONS

7.3.1 ADD – ADD A CONSTANT TO A SPECIFIED ARRAY

The ADD keyword adds a constant to a specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the ADD keyword is being applied.

See *ADD – Add a Constant to a Specified Array* in the GRID section for a full description.

7.3.2 ADDREG – ADD A CONSTANT TO AN ARRAY BASED ON A REGION NUMBER

The ADDREG keyword adds a constant to a specified array or part of an array based on cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the ADDREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the ADDREG keyword is being used.

See *ADDREG – Add a Constant to an Array based on a Region Number* in the GRID section for a full description.

7.3.3 BOUNDARY – DEFINE A BOUNDARY BOX FOR PRINTING

The BOUNDARY keyword defines a rectangular grid for printing various arrays to the output print file (*.PRT); thus, avoiding printing all the elements in the selected array.

See *BOUNDARY – Define a Boundary Box for Printing* in the GRID section for a full description.

7.3.4 BOX - DEFINE A RANGE OF GRID BLOCKS TO ENTER PROPERTY DATA

BOX defines a range of grid blocks for which subsequent data is assigned for all the cells in the defined BOX. Note that the BOX grid is reset by the keyword ENDBOX by resetting the current defined BOX to be the whole grid. The keyword can be used for any array and for all grid types.

See *BOX - Define a Range of Grid Blocks to Enter Property Data* in the GRID section for a full description.

7.3.5 COLUMNS – DEFINE INPUT FILE COLUMN MARGINS

The COLUMNS keyword defines the input file column margins; characters outside the margins are ignored by the input parser.

See *COLUMNS – Define Input File Column Margins* in the GLOBAL section for a full description.

7.3.6 COPY – COPY ARRAY DATA TO ANOTHER ARRAY

The COPY keyword copies an array (or part of an array) to another array or part of an array. The arrays can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the COPY keyword is being used.

See *COPY – Copy Array Data to Another Array* in the GRID section for a full description.

7.3.7 COPYREG – COPY AN ARRAY TO ANOTHER ARRAY BASED ON A REGION NUMBER

The COPYREG keyword copies a specified array or part of an array based on cells with a specific region number to another array. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the COPYREG keyword is read by the simulator. The property arrays can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the COPYREG keyword is being used.

See *COPYREG – Copy an Array to Another Array based on a Region Number* in the GRID section for a full description.

7.3.8 DEBUG – DEFINE THE DEBUG DATA TO BE PRINTED TO FILE

This keyword defines the debug data to be written to the debug file (*.DBG). This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

See *DEBUG – Define the Debug Data to be Printed to File* in the GLOBAL section for a full description.

7.3.9 DEPTH - EDITS THE DEPTH AT THE CENTER OF EACH CELL

Description

The DEPTH keywords modifies the depth at the center of selected cells in the model. The cells DEPTH are calculated by OPM Flow at the end of the GRID section and this keyword allows the user to adjust the calculated depths in the EDIT section. The area to be modified can be defined via the various grid selection keywords, ADD, BOX, EQUALS, etc., and areas that are not selected remain unchanged.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DEPTH	DEPTH is an array of real numbers defining the depth at the center of each cell in the model. Only the values in the currently defined input BOX needed be entered. Repeat counts may be used, for example 30*5201.0.			
		feet	m	cm	None
Notes: 1) The keyword is terminated by a "/".					

Table 7.2: Depth Keyword Description

See also the TOPS keyword to define the top structural depth for the cells.

Examples

The example below modifies the DEPTH of the cells for a selection of 10 cells from an NX = 10, NY = 11 and NZ = 20 model.

```
--
--        DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--        ---------- BOX ---------
--        I1  I2   J1  J2   K1  K2
BOX
          1  10   11  11   20  20 / SET BOX AREA TO BE MODIFIED
/
--
--        SET GRID BLOCK CENTER DEPTH FOR THE GRID BLOCKS
--
DEPTH     10*3500.0                                                    /
--
--        DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

Alternatively the EQUALS keyword can be used to perform the same edit.

```
--
--        ARRAY       CONSTANT     ---------- BOX ---------
--                                 I1  I2   J1  J2   K1  K2
EQUALS
          DEPTH       3500.0        1  10   11  11   20  20 / RESET DEPTH
/
```

7.3.10 DIFFR – DEFINE GRID BLOCK RADIAL DIRECTION DIFFUSIVITY VALUES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFR keyword defines the radial direction diffusivity values for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

7.3.11 DIFFTHT – DEFINE GRID BLOCK THETA DIRECTION DIFFUSIVITY VALUES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFTHT keyword defines the theta direction diffusivity values for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

7.3.12 DIFFX – DEFINE GRID BLOCK X-DIRECTION DIFFUSIVITY VALUES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFX keyword defines the x-direction diffusivity values for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

7.3.13 DIFFY – DEFINE GRID BLOCK Y-DIRECTION DIFFUSIVITY VALUES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFY keyword defines they y-direction diffusivity values for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

7.3.14 DIFFZ – DEFINE GRID BLOCK Z-DIRECTION DIFFUSIVITY VALUES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFZ keyword defines the z-direction diffusivity values for cells in the current input box for when the Diffusivity option has been activated by the DIFFUSE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

7.3.15 ECHO – ACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns on echoing of all the input files to the print file; note that this keyword is activated by default and can subsequently be switched off by the NOECHO activation keyword.

See *ECHO – Activate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

7.3.16 EDIT - DEFINE THE START OF THE EDIT SECTION OF KEYWORDS

Description

The EDIT activation keyword marks the end of the GRID section and the start of the EDIT section that enables modifications to the OPM Flow calculated properties derived from the data entered in the GRID section, for example grid block pore volumes via the PORV array and the transmissibilities via the TRANX, TRANY and TRANZ family of keywords.

There is no data required for this keyword.

Example

```
-- ==========================================================================
--
-- EDIT SECTION
--
-- ==========================================================================
EDIT
```

The above example marks the end of the GRID section and the start of the EDIT section in the OPM Flow data input file.

7.3.17 EDITNNC – SCALE NON-NEIGHBOR CONNECTIONS BETWEEN CELLS MANUALLY

Description

EDITNNC enables Non-Neighbor Connections ("NNC"), entered via the NNC keyword or calculated by the simulator, to be multiplied (re-scaled) by a constant. For example, if the existing transmissibility between non-neighbor connections is Told and the multiplier is C, then the resulting transmissibility, Tnew, will be $T_{new} = C \ x \ T_{old}$. Only previously defined NNC's entered via the NNC keyword or calculated by the simulator can be edited, otherwise a warning message will be printed.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	I1	A positive integer that defines the first grid block in the I-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NX on the DIMENS keyword in the RUNSPEC section.			None
2	J1	A positive integer that defines the first grid block in the J-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NY on the DIMENS keyword in the RUNSPEC section.			None
3	K1	A positive integer that defines the first grid block in the K-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NZ on the DIMENS keyword in the RUNSPEC section.			None
4	I2	A positive integer that defines the second grid block in the I-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NX on the DIMENS keyword in the RUNSPEC section.			None
5	J2	A positive integer that defines the second grid block in the J-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NY on the DIMENS keyword in the RUNSPEC section.			None
6	K2	A positive integer that defines the second grid block in the K-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NZ on the DIMENS keyword in the RUNSPEC section.			None
7	TRANSMUL	TRANSMUL is a positive real number greater than or equal to zero that defines a constant that scales the transmissibility between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2). The default value of one means no scaling will be applied.			
		dimensionless	dimensionless	dimensionless	1
8	ISATNUM1	The default value of zero means the existing saturation table allocated to the upstream cell (I1,J1,K1).			0
9	ISATNUM2	ISATNUM2 is a positive integer defining which saturation table number (relative permeability table) to be used for flow from the second grid block to the first grid block. The default value of zero means the existing saturation table allocated to the downstream cell (I2,J2,K2).			0

No.	Name	Description			Default
		Field	Metric	Laboratory	
10	IPRSNUM1	IPRSNUM1 is a positive integer defining which pressure table number (PVT table) to be used for flow from the first grid block to the second grid block. The default value of zero means the existing PVT table allocated to the upstream cell (I1,J1,K1).			0
11	IPRSNUM2	IPRSNUM2 is a positive integer defining which pressure table number (PVT table) to be used for flow from the second grid block to the first grid block. The default value of zero means the existing PVT table allocated to the downstream cell (I2,J2,K2).			0
12	FACE1	FACE1 is a character string that defines the face associated with flow from the first grid block to the second grid block, where FACE1 can have values of: X+, X-, Y+, Y-, Z+, or Z-. FACE1 is used with the commercial simulator's Vertical Equilibrium option which is not supported by OPM Flow.			None
13	FACE2	FACE2 is a character string that defines the face associated with flow from the second grid block to the first grid block, where FACE2 can have values of: X+, X-, Y+, Y-, Z+, or Z-. FACE2 is used with the commercial simulator's Vertical Equilibrium option which is not supported by OPM Flow.			None
14	DIFFNNC	DIFFNNC is a positive real number greater than or equal to zero that scales the diffusivity between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2).			
		dimensionless	dimensionless	dimensionless	0.0

Notes:

1) Each record must be terminated by a "/" and the keyword is terminated by a "/".

Table 7.3: EDITNNC Keyword Description

Note that although items (8) to (14) for this keyword are not available in OPM Flow, even if they were, it is strongly recommended that these items are defaulted if the data is being entered manually, as opposed to being generated by pre-processing software.

Care should be taken that cells in different PVTNUM regions (see the PVTNUM keyword in the REGIONS section) are not connected, since the fluid properties are associated with a cell. If for example, a rbbl or a rm^3 of oil flows from PVTNUM region 1 to PVTNUM region 2, then the oil properties of that oil will change from the PVT 1 data set to the PVT data set 2. This will result in material balance errors, that may or may not cause numerical issues.

If the transmissibility across a fault needs to be modified see the FAULTS and MULTFLT keywords in the GRID section for an alternative and less complicated method to modifying fault transmissibilities. Transmissibility between reservoir regions can be modified by using MULTREGT keyword, provided MULTNUM has been used to define the inter-region transmissibility region numbers for each grid block. Finally, the MULTX, MULTY and MULTZ series of keywords can be used to modify transmissibility between various cells. All the aforementioned keywords are described in the GRID section.

See also the EDITNNCR keyword in the EDIT section that resets an existing NNC to a user defined value.

Example

```
--
--       MANUALLY RESCALE NON-NEIGHBOR CONNECTIONS
--
--       ------------ BOX -----------    -- TRANSMUL --
--       I1   J1   K1    I2   J2   K2
EDITNCC
         1    1    1     1    1    2        0.2000     / SET NNC FOR FAULT
         1    1    2     1    1    3        0.2000     / SET NNC FOR FAULT
         1    1    3     1    1    4        0.2000     / SET NNC FOR FAULT
/
```

The above example multiplies the transmissibility between cells (1, 1, 1) and (1, 1, 2), (1, 1, 2) and (1, 1, 3) and finally between (1, 1, 3) and (1, 1, 4) by 0.200.

7.3.18 EDITNNCR – RESET NON-NEIGHBOR CONNECTIONS BETWEEN CELLS MANUALLY

Description

EDITNNCR enables Non-Neighbor Connections ("NNC"), entered via the NNC keyword or calculated by the simulator, to be reset to a user defined value. Only previously defined NNC's entered via the NNC keyword or calculated by the simulator can be edited, otherwise a warning message will be printed. See also the EDITNNC keyword in the EDIT section that scales an existing NNC.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	I1	A positive integer that defines the first grid block in the I-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NX on the DIMENS keyword in the RUNSPEC section.			None
2	J1	A positive integer that defines the first grid block in the J-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NY on the DIMENS keyword in the RUNSPEC section.			None
3	K1	A positive integer that defines the first grid block in the K-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NZ on the DIMENS keyword in the RUNSPEC section.			None
4	I2	A positive integer that defines the second grid block in the I-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NX on the DIMENS keyword in the RUNSPEC section.			None
5	J2	A positive integer that defines the second grid block in the J-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NY on the DIMENS keyword in the RUNSPEC section.			None
6	K2	A positive integer that defines the second grid block in the K-direction in a non-neighbor connection, must be greater than or equal to one and less than or equal to NZ on the DIMENS keyword in the RUNSPEC section.			None
7	TRANSNNC	TRANSNNC is a positive real number greater than or equal to zero that defines the transmissibility between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2). This value cannot be defaulted and must be defined.			
		cP.rb/day/psia	cP.rm^3/day/bars	cP.rcc/hr/atm	None
8	ISATNUM1	ISATNUM1 is a positive integer defining which saturation table number (relative permeability table) to be used for flow from the first grid block to the second grid block. The default value of zero means the existing saturation table allocated to the upstream cell (I1,J1,K1).			0
9	ISATNUM2	ISATNUM2 is a positive integer defining which saturation table number (relative permeability table) to be used for flow from the second grid block to the first grid block. The default value of zero means the existing saturation table allocated to the downstream cell (I2,J2,K2).			0

No.	Name	Description			Default
		Field	Metric	Laboratory	
10	IPRSNUM1	IPRSNUM1 is a positive integer defining which pressure table number (PVT table) to be used for flow from the first grid block to the second grid block. The default value of zero means the existing PVT table allocated to the upstream cell (I1,J1,K1).			0
11	IPRSNUM2	IPRSNUM2 is a positive integer defining which pressure table number (PVT table) to be used for flow from the second grid block to the first grid block. The default value of zero means the existing PVT table allocated to the downstream cell (I2,J2,K2).			0
12	FACE1	FACE1 is a character string that defines the face associated with flow from the first grid block to the second grid block, where FACE1 can have vales of: X+, X-, Y+, Y-, Z+, or Z-.			None
13	FACE2	FACE2 is a character string that defines the face associated with flow from the second grid block to the first grid block, where FACE2 can have vales of: X+, X-, Y+, Y-, Z+, or Z-.			None
14	DIFFNNC	DIFFNNC is a positive real number greater than or equal to zero that scales the diffusivity between the first grid block (I1, J1, K1) and the second grid block (I2, J2, K2). The default value is the value calculated in the GRID section.			
		feet	meters	cm	1*
Notes: 1) Each record must be terminated by a "/" and the keyword is terminated by a "/".					

Table 7.4: EDITNNCR Keyword Description

Note that although items (8) to (14) for this keyword are not available in OPM Flow, even if they were, it is strongly recommended that these items are defaulted if the data is being entered manually, as opposed to being generated by pre-processing software.

If the transmissibility across a fault needs to be modified see the FAULTS and MULTFLT keywords in the GRID section for an alternative and less complicated method to modifying fault transmissibilities. Transmissibility between reservoir regions can be modified by using MULTREGT keyword, provided MULTNUM has been used to define the inter-region transmissibility region numbers for each grid block. Finally, the MULTX, MULTY and MULTZ series of keywords can be used to modify transmissibility between various cells. All the aforementioned keywords are described in the GRID section.

Example

```
--
--       MANUALLY RESET NON-NEIGHBOR CONNECTIONS
--
--       ------------ BOX -----------    -- TRANSNNC --
--       I1   J1   K1    I2   J2   K2
EDITNCCR
         1    1    1     1    1    2        0.2500    / RESET NNC TRANS FOR FAULT
         1    1    2     1    1    3        0.2500    / RESET NNC TRANS FAULT
         1    1    3     1    1    4        0.2500    / RESET NNC TRANS FAULT
/
```

The above example res-sets the transmissibility between cells (1, 1, 1) and (1, 1, 2), (1, 1, 2) and (1, 1, 3) and (1, 1, 3) and (1, 1, 4) to be 0.2500.

7.3.19 END – DEFINE THE END OF THE INPUT FILE

This keyword marks the end of the input file and can occur in any section. Any keywords and data after the END keyword are ignored.

See *END – Define the End of the Input File* in the GLOBAL section for a full description.

7.3.20 ENDBOX – DEFINE THE END OF THE BOX DEFINED GRID

This keyword marks the end of a previously defined BOX sub-grid as defined by a previously entered BOX keyword. The keyword resets the input grid to be the full grid as defined by the NX, NY, and NZ variables on the DIMENS keyword in the RUNSPEC section.

See *ENDBOX – Define the End of the BOX Defined Grid* in the GRID section for a full description.

7.3.21 ENDFIN – END THE DEFINITION OF A LOCAL GRID REFINEMENT

NDFIN defines the end of a Cartesian or radial local grid refinement ("LGR") definition and a LGR property definition data set.

See *ENDFIN – End the Definition of a Local Grid Refinement* in the GRID section for a full description.

7.3.22 ENDINC – DEFINE THE END OF AN INCLUDE FILE

This keyword marks the end of an include file specified on the INCLUDE keyword. When the ENDINC keyword is encountered in the INCLUDE file, input data is read from the next keyword in the current file. Any keywords and data after the ENDINC keyword in the INCLUDE file are ignored.

See *ENDINC – Define the End of an Include File* in the GLOBAL section for a full description.

7.3.23 ENDSKIP – DEACTIVATE SKIPPING OF KEYWORDS AND INPUT DATA

Turns off skipping of keywords that was activated by the SKIP, SKIP100, or SKIP300 keywords. Note that for each SKIP keyword activated there must be a corresponding ENDSKIP keyword.

See *ENDSKIP – DeActivate Skipping of Keywords and Input Data* in the GLOBAL section for a full description.

7.3.24 EQUALREG – SETS AN ARRAY TO A CONSTANT BY REGION NUMBER

The EQUALREG keyword sets a specified array to a constant for cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the EQUALREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the EQUALREG keyword is being used.

See *EQUALREG – Sets an Array to a Constant by Region Number* in the GRID section for a full description.

7.3.25 EQUALS – SETS A SPECIFIED ARRAY TO A CONSTANT

The EQUALS keyword sets a specified array or part of an array to a constant. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the EQUALS keyword is being used.

See *EQUALS – Sets a Specified Array to a Constant* in the GRID section for a full description.

7.3.26 EXTRAPMS – ACTIVATE EXTRAPOLATION WARNING MESSAGES

The EXTRAPMS keyword activates extrapolation warning messages for when OPM Flow extrapolates the PVT or VFP tables. Frequent extrapolation warning messages should be investigated and resolved as this would indicate possible incorrect data and may result in the simulator extrapolating to unrealistic values.

See *EXTRAPMS – Activate Extrapolation Warning Messages* in the GLOBAL section for a full description.

7.3.27 FILEUNIT – ACTIVATE UNIT CONSISTENCY VERIFICATION

The FILEUNIT keyword defines the units of the of the data set, and is used to verify that the units in the input deck and any associated include files are consistent grid data. The keyword does not provide for the conversion between different sets of units.

See *FILEUNIT – Activate Unit Consistency Checking* in the GRID section for a full description.

7.3.28 FORMFEED – DEFINED THE PRINT FILE FORM-FEED CHARACTER

The FORMFEED keyword defines the form-feed character, or carriage control character, for the output print (*.PRT) run summary (*.RSM) files. The keyword should be place at the very top of the input file.

See *FORMFEED – Defined the Print File Form-Feed Character* in the GLOBAL section for a dull description.

7.3.29 GETDATA – LOAD AND ASSIGN DATA ARRAY FROM INIT OR RESTART FILE

The GETDATA keyword loads a data array from a previously generated INIT or RESTART file and assigns the loaded array to either same array in the run or another array name.

See *GETDATA – Load and Assign Data Array from INIT or RESTART Files* in the GRID section for a full description

7.3.30 HMMULT – HISTORY MATCH GRID TRANSMISSIBILITY & PORE VOLUME GRADIENT CUMULATIVE MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HMMULT series of keywords defines the history match gradient cumulative permeability multipliers, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. The keyword consists of the first six characters of "HMMULT" followed by a one or two character string shown in Table 7.5, that determines the transmissibility direction, for example, HMMULTX.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Mnemonic	Cartesian Grid		Radial Grid	
	Grid Keyword	HMMULT Keyword	Grid Keyword	HMMULT Keyword
X/R	MULTX	HMMULTX	MULTR	HMMULTR
XY	MULTXY	HMMULTXY		
Y/HT	MULTY	HMMULTY	MULTTHT	HMMULTTH
Z	MULTZ	HMMULTZ	MULTZ	HMMULTZ
PV	MULTPV	HMMULTPV	MULTPV	HMMULTPV

Table 7.5: HMMULT Keyword List

See also the HMMLT keyword in the GRID section.

7.3.31 IMPORT – IMPORT GRID FILE DATA AT THE CURRENT POSITION

The IMPORT keyword informs the simulator to continue reading input data from the specified IMPORT file. When the end of the IMPORT file is reached, input data is read from the next keyword in the current file. Normally IMPORT files are generated by grid pre-processing software and the keyword allows for both formatted and unformatted (binary) files to be loaded.

See *IMPORT – Import Grid File Data at the Current Position* in the GRID section for a full description.

7.3.32 INCLUDE – LOAD ANOTHER DATA FILE AT THE CURRENT POSITION

The INCLUDE keyword informs OPM Flow to continue reading input data from the specified INCLUDE file. When the end of the INCLUDE file is reached, or the ENDINC keyword is encountered in the included file, input data is read from the next keyword in the current file.

See *INCLUDE – Load Another Data File at the Current Position* in the GLOBAL section for a full description.

7.3.33 LGRCOPY – ACTIVATE LOCAL GRID REFINEMENT INHERITANCE

The LGRCOPY keyword actives Local Grid Refinement ("LGR") Inheritance option that allows the LGR to inherit the properties of the global or host cell containing a LGR grid block at the start of the GRID section, as oppose to the normal process of applying this transform at the end of the GRID section. LGRCOPY can be used in the RUNSPEC, GRID and EDIT sections. If used in the RUNSPEC section then the option is applied to all LGRs defined in the input file, whereas if used in the GRID and EDIT sections the keyword must be placed inside a LGR definition section, that is between a CARFIN (Cartesian LGR grid) or RADIN/RADIN4 (radial LGR grid) and the ENDFIN keyword. In the latter case inheritance is applied on an individual LGR basis.

See *LGRCOPY – Activate Local Grid Refinement Inheritance* in the RUNSPEC section for a full description.

7.3.34 MAXVALUE – SETS A MAXIMUM VALUE FOR AN ARRAY ELEMENT

The MAXVALUE keyword sets a maximum value for the specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the MAXVALUE keyword is being used.

See *MAXVALUE – Sets a Maximum Value for an Array Element* in the GRID section for a full description.

7.3.35 MESSAGE – OUTPUT USER MESSAGE

The MESSAGE keyword outputs a user message to the terminal, as well as to the print (*.PRT) and debug (*.DBG) files. Note this is different to the MESSAGES keyword, that defines OPM Flows message print limits and stop limits generated by the simulator.

See *MESSAGE – Output User Message* in the GLOBAL section for a full description.

7.3.36 MESSAGES – DEFINE MESSAGE PRINT LIMITS AND STOP LIMITS

The MESSAGES keyword defines the print and stops levels for various messages. The "print limits" set the maximum number of messages that will be printed, after which no more messages will be printed and the "stop limits" terminate the run when these limits are exceeded. There are six levels of message that increase in severity from informative all the way to programming errors, as outlined in Error: Reference source not found.

See *MESSAGES – Define Message Print Limits and Stop Limits* in the GLOBAL section for a full description.

7.3.37 MINVALUE – SET A MINIMUM VALUE FOR AN ARRAY ELEMENT

The MINVALUE keyword sets a minimum value for the specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the MINVALUE keyword is being used.

See *MINVALUE – Set a Minimum Value for an Array Element* in the GRID section for a full description.

7.3.38 MULTFLT – MULTIPLY THE TRANSMISSIBILITY OF A DEFINED FAULT BY A CONSTANT

MULTFLT enables the transmissibilities across defined faults, as declared by the FAULTS keyword, to be modified. They keyword allows for the re-scaling of the existing fault transmissibilities calculated by OPM Flow, for example setting a fault to be completely sealing by setting the multiplier to zero..

See *MULTFLT – Multiply the Transmissibility of a Defined Fault by a Constant* in the GRID section for a full description.

7.3.39 MULTIPLY – MULTIPLY A SPECIFIED ARRAY BY A CONSTANT

The MULTIPLY keyword multiplies a specified array or part of an array by a constant. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

See *MULTIPLY – Multiply a Specified Array by a Constant* in the GRID section for a full description.

7.3.40 MULTIREG – MULTIPLY AN ARRAY BY A CONSTANT BASED ON A REGION NUMBER

The MULTIREG keyword multiplies an array or part of an array by a constant for cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTIREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the MULTIREG keyword is being used.

See *MULTIREG – Multiply an Array by a Constant based on a Region Number* in the GRID section for a full description.

7.3.41 MULTPV – MULTIPLY CELL PORE VOLUMES BY A CONSTANT

MULTPV multiples the pore volumes of a cell by a real positive constant for all the cells in the model via an array. An alternative to defining the complete array is to use the BOX keyword to define an area of the grid and then use the MULTPV keyword to set the multipliers just for the area defined by the BOX keyword (see the example).

See *MULTPV – Multiply Cell Pore Volumes by a Constant*in the GRID section for a full description.

7.3.42 MULTR - MULTIPLY CELL TRANSMISSIBILITY IN THE +R DIRECTION

MULTR multiples the transmissibility between two cell faces in the +R direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I+I, J, K). The keyword should only be used with radial grids, as declared by the RADIAL keyword in the RUNSPEC section.

See *MULTR - Multiply Cell Transmissibility in the +R Direction* in the GRID section for a full description.

7.3.43 MULTR- - MULTIPLY CELL TRANSMISSIBILITY IN THE -R DIRECTION

MULTX- multiples the transmissibility between two cell faces in the -X direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I-1, J, K) and (I, J, K). The keyword should only be used with radial grids, as declared by the RADIAL keyword in the RUNSPEC section.

See *MULTR- - Multiply Cell Transmissibility in the -R Direction* in the GRID section for a full description.

7.3.44 MULTREGD – MULTIPLY DIFFUSIVITIES BETWEEN REGIONS

The MULTREGT keyword multiplies the diffusivity between two regions by a constant. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGT keyword is read by the simulator. The constant should be a real number.

See *MULTREGD – Multiply Diffusivities Between Regions* in the GRID section for a full description.

7.3.45 MULTREGH – MULTIPLY THERMAL CONDUCTIVITIES BETWEEN REGIONS

The MULTREGH keyword multiplies the thermal conductivity between two regions by a constant. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGT keyword is read by the simulator. The constant should be a real number.

See *MULTREGH – Multiply Thermal Conductivities Between Regions* in the GRID section for a full description.

7.3.46 MULTREGP– MULTIPLY PORE VOLUMES BASED ON REGION NUMBER

The MULTREGP keyword multiplies the pore volume of a cell by a constant for all cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGP keyword is read by the simulator. The constant should be a real number.

See *MULTREGP – Multiply Pore Volumes Based On Region Number* in the GRID section for a full description.

7.3.47 MULTREGT– MULTIPLY TRANSMISSIBILITIES BETWEEN REGIONS

The MULTREGT keyword multiplies the transmissibility between two regions by a constant. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTREGT keyword is read by the simulator. The constant should be a real number.

See *MULTREGT – Multiply Transmissibilities Between Regions*in the GRID section for a full description.

7.3.48 MULTTHT - MULTIPLY CELL TRANSMISSIBILITY IN THE +THETA DIRECTION

MULTTHT multiples the transmissibility between two cell faces in the +Theta direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I, J+1, K). The keyword should only be used with radial grids, as declared by the RADIAL keyword in the RUNSPEC section.

See *MULTTHT - Multiply Cell Transmissibility in the +Theta Direction* in the GRID section for a full description.

7.3.49 MULTTHT- - MULTIPLY CELL TRANSMISSIBILITY IN THE -THETA DIRECTION

MULTTHT- multiples the transmissibility between two cell faces in the -Theta direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J-1, K) and (I, J, K). The keyword should only be used with radial grids, as declared by the RADIAL keyword in the RUNSPEC section.

See *MULTTHT- - Multiply Cell Transmissibility in the -Theta Direction* in the GRID section for a full description.

7.3.50 MULTX - MULTIPLY CELL TRANSMISSIBILITY IN THE +X DIRECTION

MULTX multiples the transmissibility between two cell faces in the +X direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I+1, J, K).

See *MULTX - Multiply Cell Transmissibility in the +X Direction* in the GRID section for a full description.

7.3.51 MULTX- - MULTIPLY CELL TRANSMISSIBILITY IN THE -X DIRECTION

MULTX- multiples the transmissibility between two cell faces in the -X direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I-1, J, K) and (I, J, K).

See *MULTX- - Multiply Cell Transmissibility in the -X Direction* in the GRID section for a full description.

7.3.52 MULTY - MULTIPLY CELL TRANSMISSIBILITY IN THE +Y DIRECTION

MULTY multiples the transmissibility between two cell faces in the +Y direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I, J+1, K).

See *MULTY - Multiply Cell Transmissibility in the +Y Direction* in the GRID section for a full description.

7.3.53 MULTY- - MULTIPLY CELL TRANSMISSIBILITY IN THE -Y DIRECTION

MULTY- multiples the transmissibility between two cell faces in the -Y direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J-1, K) and (I, J, K).

See *MULTY- - Multiply Cell Transmissibility in the -Y Direction* in the GRID section for a full description.

7.3.54 MULTZ - MULTIPLY CELL TRANSMISSIBILITY IN THE +Z DIRECTION

MULTZ multiples the transmissibility between two cell faces in the +Z direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K) and (I, J, K+1).

See *MULTZ - Multiply Cell Transmissibility in the +Z Direction* in the GRID section for a full description.

7.3.55 MULTZ- - MULTIPLY CELL TRANSMISSIBILITY IN THE -Z DIRECTION

MULTZ- multiples the transmissibility between two cell faces in the -Z direction for all the cells in the model via an array, that is the keyword sets the transmissibility multiplier of block (I, J, K) between the cells (I, J, K-1) and (I, J, K).

See *MULTZ- - Multiply Cell Transmissibility in the -Z Direction* in the GRID section for a full description.

7.3.56 NOECHO – DEACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns off echoing of all the input files to the print file. Note by default echoing of the inputs files is active. but can subsequently be switched off by the NOECHO activation keyword.

See *NOECHO – Deactivate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

7.3.57 NOWARN – DEACTIVATE WARNING MESSAGES

Turns off warning messages to be printed to the print file; note that this keyword is deactivated by default and can subsequently be switched off by the WARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN.

See *NOWARN – Deactivate Warning Messages* in the GLOBAL section for a full description.

7.3.58 OPERATE – DEFINE MATHEMATICAL OPERATIONS ON ARRAYS

This keyword, OPERATE, defines mathematical operations on property arrays (NTG, PORO etc.) and optionally using another property array as input to the function. The keyword allows for various mathematical functions and their associated variables to be defined and applied to the selected array data. Input constants can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

See *OPERATE – Define Mathematical Operations on Arrays* in the GRID section for a full description.

7.3.59 OPERATER – DEFINE MATHEMATICAL OPERATIONS ON ARRAYS BY REGION

This keyword defines the mathematical operations on arrays for specific regions in the commercial simulator and is currently not supported by OPM Flow. However, similar functionality is provided by the ADD and MULTIPLY keywords.

See *OPERATER – Define Mathematical Operations on Arrays by Region* in the GRID section for a full description.

7.3.60 PORV - DEFINE THE PORE VOLUMES FOR ALL THE CELLS

Description

PORV defines the pore volumes for all the cells in the model via an array. The keyword can be used for all grid types, except for the Radial Grid geometry. The keyword effectively overwrites previously entered and calculated data. The area to be modified can be defined via the various grid selection keywords, ADD, BOX, EQUALS, etc., and areas that are not selected remain unchanged.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PORV	PORV is an array of real positive numbers assigning a pore volume to each cell in the model. Only the values in the currently defined input BOX needed be entered. Repeat counts may be used, for example 20*100.0.			
		rb	rm^3	rcc	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) Values not reset by this keyword remain unaltered.
3) The keyword is terminated by a "/".

Table 7.6: PORV Keyword Description

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1* 100   1* 100   20  20                          / DEFINE BOX AREA
--
--       SET PORV FOR THE GRID BLOCKS
--
PORV
         1000*0.00                                        /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

Here the BOX statement is used to define the input grid for the PORV keyword, which overwrites the pore volume previously calculated with pore volume values of zero, resulting in a no-flow boundary in that part of the field between layers 19 and 21, since layer 20 is deactivated. The ENDBOX keyword resets the input box to the full grid.

7.3.61 PYEND – END THE DEFINITION OF A PYINPUT SECTION

The PYINPUT and PYEND keywords are a part of OPM Flow's Python scripting facility that processes standard Python commands that can be used to manipulate and define the simulators input parameters during processing of the input deck. The main purpose of the facility is to script the construction of the various keywords. A PYINPUT Definition Section is terminated by a PYEND keyword on a separate single line.

See *PYEND – End the Definition of a PYINPUT Section* in the GRID section for a full description.

7.3.62 PYINPUT – DEFINE THE START OF A PYINPUT SECTION

The PYINPUT and PYEND keywords are a part of OPM Flow's Python scripting facility that processes standard Python commands that can be used to manipulate and define the simulators input parameters during processing of the input deck. The main purpose of the facility is to script the construction of the various keywords used by the simulator. PYINPUT declares the start of a PYINPUT Definition Section on a single separate line, which is then followed by various standard Python commands, with one command per line.

See *PYINPUT – Define the Start of a PYINPUT Section* in the GRID section for a full description.

7.3.63 REFINE – START THE DEFINITION OF A LOCAL GRID REFINEMENT

The REFINE keyword defines the start of a Cartesian or radial local grid refinement ("LGR") definition that sets the properties of the selected LGR. The keyword is then followed by the property keywords associated with the section where the keyword is being invoked. For example, if the REFINE keyword is used in the GRID section then most of the keywords in that section can be used to set the grid properties for the LGR.

See *REFINE – Start the Definition of a Local Grid Refinement* in the GRID section for a full description.

7.3.64 SKIP – ACTIVATE SKIPPING OF ALL KEYWORDS AND INPUT DATA

The SKIP keyword turns on skipping of keywords until the ENDSKIP activation keyword is encountered. All keywords and between the SKIP and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP – Activate Skipping of All Keywords and Input Data* in the GLOBAL section for a full description.

7.3.65 SKIP100 – ACTIVATE SKIPPING OF BLACK-OIL KEYWORDS AND INPUT DATA

This keyword turns on skipping of black-oil keywords until the ENDSKIP activation keyword is encountered. All black-oil keywords between the SKIP100 and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP100 – Activate Skipping of Black-Oil Keywords and Input Data* in the GLOBAL section for a full description.

7.3.66 SKIP300 – ACTIVATE SKIPPING OF "COMPOSITIONAL" KEYWORDS AND INPUT DATA

Turns on skipping of "compositional" keywords until the ENDSKIP activation keyword is encountered. All "compositional" keywords between the SKIP300 and ENDSKIP keywords are ignored by OPM Flow.

See *Error: Reference source not found* in the GLOBAL section for a full description.

7.3.67 TRANR - DEFINE THE TRANSMISSIBILITY IN THE +R DIRECTION FOR ALL THE CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

TRANR defines the transmissibility in the +R direction for all the cells in the model via an array. The keyword can only be used with Radial Grid geometry grids. The keyword effectively overwrites previously entered and calculated data. The transmissibility overwritten is the +R face transmissibility of each grid block, that is for cell (I, J, K) the transmissibility between cells (I, J, K) and (I+1, J, K).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TRANR	TRANR is an array of real positive numbers assigning the transmissibility in the R direction to each cell in the model. Repeat counts may be used, for example 20*100.0.			
		cP.rb/day/psia	cP.rm^3/day/bars	cP.rcc/hr/atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) Values not reset by this keyword remain unaltered.
3) The keyword is terminated by a "/".

Table 7.7: TRANR Keyword Description

See also the TRANTHT and TRANYZ keywords to modify the transmissibilities in the other directions.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1   1    10  10   1  120                        / DEFINE BOX AREA
--
--       SET TRANR+ TRANSMISSIBILITY
--
TRANR
         120*0.00                                       /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

Here the BOX statement is used to define the input grid for the TRANR keyword, which overwrites the transmissibility previously calculated with transmissibility values of zero, resulting in a no-flow boundary in that part of the grid. The ENDBOX keyword resets the input box to the full grid.

7.3.68 TRANTHT - DEFINE THE TRANSMISSIBILITY IN THE +THETA DIRECTION FOR ALL THE CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

TRANTHT defines the transmissibility in the +Theta direction for all the cells in the model via an array. The keyword can only be used with Radial Grid geometry grids. The keyword effectively overwrites previously entered and calculated data. The transmissibility overwritten is the +Theta face transmissibility of each grid block, that is for cell (I, J, K) the transmissibility between cells (I, J, K) and (I, J+1, K).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TRANTHT	TRANTHT is an array of real positive numbers assigning the transmissibility in the +Theta direction to each cell in the model. Repeat counts may be used, for example 20*100.0.			
		cP.rb/day/psia	cP.rm^3/day/bars	cP.rcc/hr/atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) Values not reset by this keyword remain unaltered.
3) The keyword is terminated by a "/".

Table 7.8: TRANR Keyword Description

See also the TRANR and TRANYZ keywords to modify the transmissibilities in the other directions.

Example

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         10  10   1   6    1   3                          / DEFINE BOX AREA
--
--       SET TRANTHT TRANSMISSIBILITY
--
TRANTHT
         18*0.00                                         /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

Here the BOX statement is used to define the input grid for the TRANTHT keyword, which overwrites the transmissibility previously calculated with transmissibility values of zero, resulting in a no-flow boundary in that part of the grid. The ENDBOX keyword resets the input box to the full grid.

7.3.69 TRANX - DEFINE THE TRANSMISSIBILITY IN THE X DIRECTION FOR ALL THE CELLS

Description

TRANX defines the transmissibility in the X direction for all the cells in the model via an array. The keyword can be used for all grid types, except for the Radial Grid geometry. The keyword effectively overwrites previously entered and calculated data. The transmissibility overwritten is the +X face transmissibility of each grid block, that is for cell (I, J, K) the transmissibility between cells (I, J, K) and (I+1, J, K).

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TRANX	TRANX is an array of real positive numbers assigning the transmissibility in the X direction to each cell in the model. Repeat counts may be used, for example 20*100.0.			
		cP.rb/day/psia	cP.rm^3/day/bars	cP.rcc/hr/atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) Values not reset by this keyword remain unaltered.
3) The keyword is terminated by a "/".

Table 7.9: TRANX Keyword Description

See also the TRANY and TRANYZ keywords to modify the transmissibilities in the other directions.

Example

```
--
--        DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--        ---------- BOX ---------
--        I1  I2   J1  J2   K1  K2
BOX
          1   1    10  10   1  120                          / DEFINE BOX AREA
--
--        SET TRANX+ TRANSMISSIBILITY
--
TRANX
          120*0.00                                         /
--
--        DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

Here the BOX statement is used to define the input grid for the TRANX keyword, which overwrites the transmissibility previously calculated with transmissibility values of zero, resulting in a no-flow boundary in that part of the field. The ENDBOX keyword resets the input box to the full grid.

7.3.70 TRANY - DEFINE THE TRANSMISSIBILITY IN THE Y DIRECTION FOR ALL THE CELLS

Description

TRANY defines the transmissibility in the Y direction for all the cells in the model via an array. The keyword can be used for all grid types, except for the Radial Grid geometry. The keyword effectively overwrites previously entered and calculated data. The transmissibility overwritten is the +Y face transmissibility of each grid block, that is for cell (I, J, K) the transmissibility between cells (I, J, K) and (I, J+1, K).

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TRANY	TRANY is an array of real positive numbers assigning the transmissibility in the Y direction to each cell in the model. Repeat counts may be used, for example 20*100.0.			
		cP.rb/day/psia	cP.rm^3/day/bars	cP.rcc/hr/atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) Values not reset by this keyword remain unaltered.
3) The keyword is terminated by a "/".

Table 7.10: TRANY Keyword Description

See also the TRANX and TRANZ keywords to modify the transmissibilities in the other directions.

Example

```
--
--        DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--        ---------- BOX ---------
--        I1  I2   J1  J2   K1  K2
BOX
          1   1    10  10   1  120                          / DEFINE BOX AREA
--
--        SET TRANY+ TRANSMISSIBILITY
--
TRANY
          120*0.00                                         /
--
--        DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

Here the BOX statement is used to define the input grid for the TRANY keyword, which overwrites the transmissibility previously calculated with transmissibility values of zero, resulting in a no-flow boundary in that part of the field. The ENDBOX keyword resets the input box to the full grid.

7.3.71 TRANZ - DEFINE THE TRANSMISSIBILITY IN THE Z DIRECTION FOR ALL THE CELLS

Description

TRANX defines the transmissibility in the z direction for all the cells in the model via an array. The keyword can be used for all grid types, except for the Radial Grid geometry. The keyword effectively overwrites previously entered and calculated data. The transmissibility overwritten is the +Z face transmissibility of each grid block, that is for cell (I, J, K) the transmissibility between cells (I, J, K) and (I, J, K+1).

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TRANZ	TRANZ is an array of real positive numbers assigning the transmissibility in the Z direction to each cell in the model. Repeat counts may be used, for example 20*100.0.			
		cP.rb/day/psia	cP.rm^3/day/bars	cP.rcc/hr/atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) Values not reset by this keyword remain unaltered.
3) The keyword is terminated by a "/".

Table 7.11: TRANZ Keyword Description

See also the TRANX and TRANY keywords to modify the transmissibilities in the other directions.

Example

```
--
--        DEFINE INPUT BOX FOR EDITING INPUT ARRAYS
--
--        ---------- BOX ---------
--        I1  I2   J1  J2   K1  K2
BOX
          1* 100   1* 100   20  20                          / DEFINE BOX AREA
--
--        SET TRANZ+ TRANSMISSIBILITY
--
TRANZ
          1000*0.00                                        /
--
--        DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

Here the BOX statement is used to define the input grid for the TRANZ keyword, which overwrites the transmissibility previously calculated with transmissibility values of zero, resulting in a no-flow boundary in that part of the field between layers 20 and 21. The ENDBOX keyword resets the input box to the full grid.

7.3.72 WARN – ACTIVATE WARNING MESSAGES

Turns on warning messages to be printed to the print file (*.PRT); note that this keyword is activated by default and can subsequently be switched off by the NOWARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN. OPM Flow always prints error messages.

See *WARN – Activate Warning Messages* in the GLOBAL section for a full description.

CHAPTER 8: PROPS SECTION

8.1 INTRODUCTION

The PROPS section is the section that contains the fluid property keywords used to define the PVT behavior of the fluids in the model and therefore the data is fluid type dependent. For example, if the oil phase has been activated in the RUNSPEC section via the OIL keyword then one of the oil PVT keywords needs to be defined in this section. The other main type of data required for the PROPS section is the saturation tables that govern how the various fluids flow in the model relative to the other phases. Again, the saturation tables are fluid type dependent.

Various other fluid and rock property data are also entered in this section including rock compressibility via the ROCK keyword for the standard rock compressibility model, and rather unusually, the Carter-Tracy influence function entered via the AQUTAB keyword.

8.2 DATA REQUIREMENTS

For all phases activated in the model a complete description of the PVT behavior (PVT tables) and fluid flow behavior (saturations tables) is required. As the data is fluid type dependent, the next two sections attempt to define the appropriate keywords for the various activated fluid types. The first section outlines the fluid PVT property requirements and the second section summarizes the keywords associated with fluid flow property data, namely the relative permeability and capillary pressure data.

8.2.1 FLUID PROPERTIES

A phase is a portion of a system which is (1) homogeneous in composition, (2) bounded by a physical surface, and (3) mechanically separable from other phases which may be present. The most important phases which occur in petroleum production are a liquid phase (oil, distillate, condensate, and water) and a vapor or gas phase (natural gas) component. Separators are used to separate the gas, water and hydrocarbon liquid phases produced from wells. Solid phases also occur in petroleum production, mainly as:

(1) paraffin or other deposits within the producing formation, in the tubing, and in the surface equipment;

(2) gas hydrates which may freeze and clog gas-flow lines and equipment; and

(3) sand or reservoir rock[137].

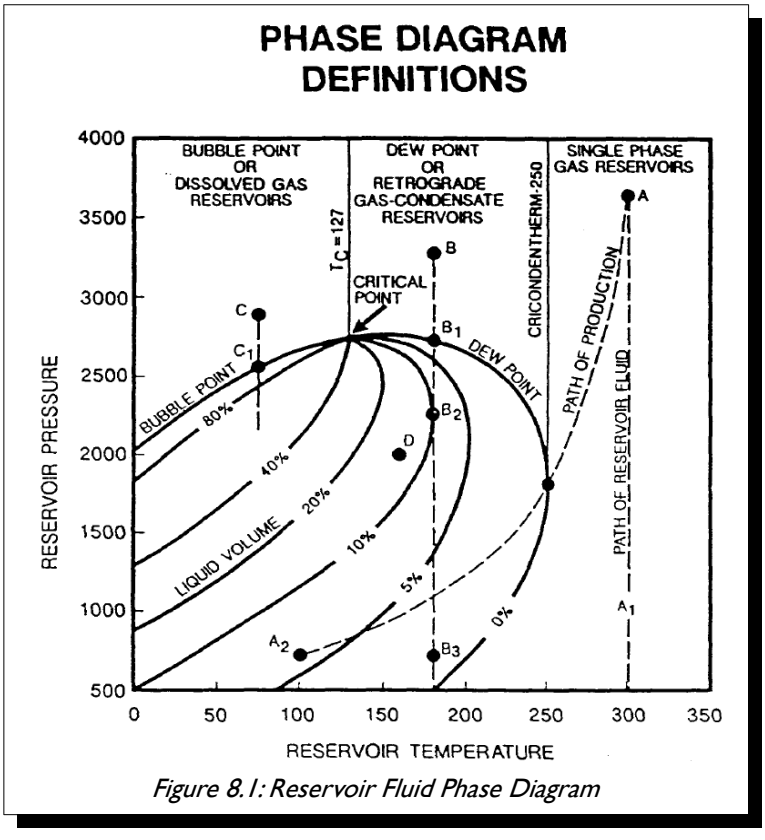

Figure 8.1: Reservoir Fluid Phase Diagram

The phase behavior of petroleum systems is represented by a Pressure-Volume-Temperature ("PVT") phase diagram, as illustrated in Figure 8.1, which shows a typical phase diagram after Clark[138].

[137] *Bradley, H. B.: "Petroleum Engineering Handbook", Society of Petroleum Engineers, Richardson, Texas, USA.*

[138] *Clark, Norman, "It Pays to Know Your Petroleum", World Oil, March and April, 1953.*

Several important definitions should be noted from Figure 8.1 that describes how a fluid behaves with respect to the composition, pressure and temperature, namely:

- **Bubble Point**: Pressure at which the first bubble of gas is formed.
- **Dew Point**: Pressure at which the last drop of liquid turns to gas.
- **Critical Point**: Point at which all properties of liquid and gas are identical, the point where the dew point and bubble point curves join.
- **Cricondentherm**: Temperature above which two phases cannot co-exist regardless of pressure.
- **Cricondenbar**: Pressure above which two phases cannot co-exist regardless of the temperature

Multi-component hydrocarbon systems are most accurately defined by their compositions, which are usually expressed as mole fractions of the components methane, ethane, propane, isobutane, n-butane, iso-pentane, n-pentane, hexanes, and heptanes and heavier (heptanes plus). The heptanes-plus fraction is usually defined by its average molecular weight, its specific gravity, and/or the fractions which boil off in selected temperature ranges. In addition to hydrocarbons, many naturally occurring petroleum systems also contain hydrogen sulphide, nitrogen, carbon dioxide, and helium in quantities which are sufficiently large to appreciably affect the phase behavior of the system (see GPA Standard 2145[139] and Standing (1952)[140] for additional information).

Gas Fluid Properties

The Ideal Gas Law is based on the above theory of gases, a mathematical equation called an Equation-of-State can be derived to express the relationship existing between pressure, volume, and temperature, for a given quantity of gas. This relationship is called the Ideal Gas Law, and is expresses mathematically as:

$$PV = nRT \tag{8.1}$$

Where,

P	=	pressure (psia or kPa).
T	=	temperature (°R = 459.67 + °F or K = 273.15 + °C).
V	=	volume of the gas (ft^3 or m^3).
n	=	number of lb moles of gas, where one lb mole is the molecular weight of the gas expressed in pounds (lb-mole or g-mol).
R	=	universal gas constant which has the value of 10.732 psia/ft^3/mole/°R or 8.314 kPa/m^3/g/mol/K.

However, the above equation of state is not applicable for **Real Gases** observed in petroleum reservoirs. In dealing with gases at a very low pressure, the ideal gas relationship (equation of state) is a convenient and accurate, within 2 - 3% at atmospheric conditions, while for pressures and temperatures found in petroleum reservoirs the physical properties calculated can lead to errors in excess of 500%. This is because real gases (natural gases) do not behavior as an ideal gas. Basically the magnitude of deviations of real gases from the conditions of the ideal gas law increases with increasing pressure and temperature, and varies widely with the composition of the gas. The reason for this is that the perfect gas law was derived under the assumption that the volume of molecules is insignificant and molecular attraction or repulsion takes place. This is not the case for real gases.

In order to express a more exact relationship between the variables P, V, and T, a correction factor called the gas compressibility factor (the gas deviation factor, or simply the Z-factor) must be introduced into the ideal gas law, that is:

[139] *Gas Processors Association, GPA, "Standard 2145 - Physical Constants of Paraffin Hydrocarbons and Other Components of Natural gas", 1986.*

[140] *Standing, M. B.:" Volumetric and Phase Behaviour of Oil Field Hydrocarbon Systems", Renihold Publishing Corp., New York City (1952).*

$$PV = ZnRT \tag{8.2}$$

Where,

P	=	pressure (psia or kPa)
T	=	temperature (°R = 459.67 + °F or K = 273.15 + °C)
V	=	volume of the gas (ft^3 or m^3)
n	=	number of lb moles of gas, where one lb mole is the molecular weight of the gas expressed in pounds (lb-mole or g-mol)
R	=	universal gas constant which has the value of 10.732 psia/ft^3/mole/°R or 8.314 kPa/m^3/g/mol/K.
Z	=	compressibility factor for the real gas

For an ideal gas, the gas compressibility factor is equal to one, while for a real gas, the Z-factor is greater or less than one depending on the pressure, temperature, and composition of the gas. The Z-factor can be calculated from the composition of the gas or from various correlations including Standing[141] and Dranchuk, P. M., Purvis, R. A., and Robinson[142].

Gas Density (ρg): Depends on composition, temperature, and pressure at which the gas is measured, it is defined as the ratio of mass (m) to volume (v), that is:

$$\rho_g = \frac{m}{V} = \frac{P \ MW}{ZRT} \tag{8.3}$$

Where MW is molecular weigh of the gas and ρg has units of lbm/ft3 and kg/m3 for field and metric units, respectively in equation (8.3). Gas density is often reported as Relative Density, that is relative to air, as per 0.65 (air-1).

Gas Formation Volume Factor (Gas Expansion Factor): Is used to relate the volume of gas, as measured at reservoir conditions, to the volume of gas as measured at standard conditions (60 oF and 14.7 psia, or 15 oC and 101.325 kPa). This gas property is then defined as the actual volume occupied by a certain amount of gas at a specified pressure and temperature, divided by the same amount of gas at standard conditions. Thus the gas formation volume factor can be expressed as:

$$E = \frac{V_{sc}}{V_i} \tag{8.4}$$

And substituting equation (8.3) into (8.4) we can derive the gas formation volume factor for a given reservoir pressure and temperature:

$$E = \left(\frac{P_i}{P_{sc}}\right)\left(\frac{T_{sc}}{T_i}\right)\left(\frac{1}{Z_i}\right) \tag{8.5}$$

Note

In oilfield units when we are dealing with oil reservoirs the gas formation volume factor is more commonly denoted as Bg and has the units of rb/scf. Whereas for gas reservoirs, the gas formation volume factor is Eg and has the units scf/rcf and is often described as the Gas Expansion Factor or GEF.

[141] *Standing, M.B. and Katz, D.L.: "Density of Natural Gases," Trans., AIME (1942) 146, 140-44.*

[142] *Dranchuk, P. M., Purvis, R. A., and Robinson, D. B., "Computer Calculations of Natural Gas Compressibility Factors Using the Standing and Katz Correlation", Institute of Petroleum Technical Series, No. IP 74-008, 1974.*

Gas Isothermal Compressibility: A knowledge of the variability of a fluid compressibility with pressure and temperature is essential in performing many reservoir engineering calculations. For a liquid phase, the compressibility is small and is usually assumed to be constant. Whereas for a gas phase, the compressibility is neither small nor constant. By definition the isothermal gas compressibility, c_g, of a substance is the change in volume per unit volume, for a unit change in pressure, i.e.

$$c_g = -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_T \tag{8.6}$$

In general all simulators calculate the isothermal gas compressibility based on the entered PVT data, so it is not necessary to enter this variable directly. If needed the correlation of Meehan, D. N., and Lyons, W. K.[143] may be used to estimate the values.

Gas Viscosity (μg): The gas viscosity of a fluid is a measure of the internal fluid friction (resistance) to flow. If the friction between layers of the fluid is small, i.e., low viscosity, an applied shearing force will result in a large velocity gradient. As viscosity increases, each fluid layer exerts a larger frictional drag on the adjacent layers and velocity gradient increases. The viscosity of a fluid is generally defined as the ratio of the shear force per unit area to the local velocity gradient. Note that gas viscosity is not normally measured in the laboratory because it can be estimated precisely from empirical correlations. Gas viscosity increases with increasing temperature and pressure. Usually it is not measured but is obtained from the Carr, Kobayashi and Burrows[144] correlation, which include corrections for H_2S, CO_2 and N_2. For sour gases, this correlation is preferred to the Lee, Gonzalez and Eakin[145] formulation (which does not account for H_2S, CO_2 and N_2). Typically, gas viscosity is in the range of 0.015 to 0.03 cp.

Condensate-Gas Ratio **("CGR"):** Defines the number of standard cubic meters of hydrocarbon liquid that will dissolve in one stock tank meter cubed of gas at a certain pressure and temperature and has units of stb/MMscf and sm^3/sm^3 for field and metric units, respectively. Field units values range from low of 1or 2 stb/MMscf for dry gas reservoirs, up to 100 stb/MMscf for wet gas reservoirs. The empirical correlation of Meethan Vogel[146] can be used to estimate CGR.(Rv)

Water Vapor Content of Gas Water Gas Ratio ("WGR"): Gas in the reservoir is usually saturated with water vapor, but as the gas moves up the wellbore, the temperature and pressure decrease and water condenses out of the gas. Often, water that is produced at the surface is not formation water but is water of condensation. Confirmation of this is a low water-gas ratio (1 – 5 bbl/MMscf) and low salinity (fresh water less 100 ppm NaCl). The water vapor content of a gas depends on pressure, temperature, and composition of the gas. As pressure decreases, the water vapor content increases. Conversely, as temperature decreases, the water vapor content decreases. Units are stb/Mscf (although often quoted as stb/MMscf) and sm^3/sm^3 for field and metric units, respectively. Bubacek's[147] empirical correlation for sweet natural gas (methane) may be used for gases without H2S to calculate GWR or McKetta and Wehe's[148] correlation that takes into account water salinity and gas gravity. Finally Robinson et al[149] and Wichert and Wichert's[150] correlations may be used for sour natural gases (those containing H2S).

Oil Fluid Properties

For oil and condensate fluids we have a similar set of properties; however, oil properties are nearly always measured experimentally in the laboratory, as although there are many correlations available, they generally have low predictability unless tuned with the laboratory measured data. Thus, the main oil properties are:

Oil Density: Like gas density, oil density depends on composition, temperature, and pressure at which the fluid is measured, it is defined as the ratio of mass (m) to volume (v), that is:

$$\rho = \frac{m}{V} \tag{8.7}$$

with units of lbm/ft^3, kg/m^3, and g/cm^3. Note that density is quoted in various units even within a given unit system. In oilfield (English) units it is quite common to quote density as a gradient that is psi/ft, this is because fluid gradients are a common form of in-situ measurement that can be easily related to density by:

$$\rho = 144 \; x \; fluid \;\; gradient \;\; (\text{psi/ft}) \tag{8.8}$$

For example, for an oil density measured as 0.338 psi/ft, the actual in-situ density would simply be:

$$\rho = 144 \; x \; 0.338 = 48.7 \; \frac{lbm}{ft^3} \tag{8.9}$$

Oil density can range as low as about 0.270 psi/ft (0.62 g/cc) in the Malay Basin (offshore Malaysia) to as high as 0.429 psi/ft (0.99 g/cc) in the heavy oil deposits in Cold Lake (Canada). However, most common oil densities range from around 0.78 - 0.85 g/cc (0.338 - 0.369 psi/ft). When using oil field units most engineers drop the m in the lbm units term, and therefore quote density as lb/ft^3 (or lb/cu. ft.), as lbm is implied.

Relative Density (γ_o) defines the ratio of the density of a known material to the density of reference material, at standard conditions of pressure and temperature. Standard conditions vary throughout the world, but for oil field units one normally uses14.7 psia and 60 °F, while for SI units some areas use 101.325 kPa and 15 °C . The reference material for liquids is always water, and thus ***Oil Relative Density*** is defined as:

$$\gamma_o = \frac{\rho_o}{\rho_{\rho w}} \tag{8.10}$$

And since the density of water at 14.7 psia and 60 °F is 62.4 lb/ft^3, then we have:

$$\gamma_o = \frac{\rho_o}{62.4} \tag{8.11}$$

For SI units, with density measured in kg/m^3, relative density is:

$$\gamma_o = \frac{\rho_o}{1000} \tag{8.12}$$

Commonly relative density is quoted with reference to the reference phase, for example, γ_o = 0.780 (water = 1).

The American Petroleum Institute ("API") classifies oils based on an API gravity (γ_{API}), or degrees API (°API), the relationship between relative density (γ_o) of oil and API gravity (γ_{API}) is given by:

$$\gamma_{API} = \frac{141.5}{\gamma_o} - 131.5 \quad (8.13)$$

Where,

γ_o	= oil gravity (water = 1.0)
ρ_o	= oil density (lb/ft^3 or kg/m^3)
API	= API gravity (°API)

API density is commonly reported at the well site.

Bubble Point (Saturation Pressure): The bubble point pressure, or saturation pressure (P_b or P_{sat}), is defined as the pressure at which the first bubbles of gas appear from a liquid as the pressure declines. The correlations given in the oil formation volume section (later on), also have the equivalent bubble point pressure correlations. It should be noted that the comments addressing the application of these correlations in the oil formation volume factor section, are equally applicable here.

Gas -Oil Ratio ("GOR"): The GOR, (R_s) is defined as the number of standard cubic meters of gas that will dissolve in one stock tank meter cubed of crude oil at a certain pressure and temperature. The solubility of a natural gas in a crude oil is a strong function of the pressure, the temperature, the API gravity, and gas gravity. For a particular gas and crude oil to exist at a constant temperature, the solubility increases with pressure until the saturation pressure is reached. At the saturation pressure (bubble point pressure) all the available gases are dissolved in the oil, and the gas solubility reaches its maximum value. Rather than measuring the amount of gas that will dissolve in given stock tank crude oil as the pressure is increased, it is customary to determine the amount of gas that will come out of the sample of reservoir crude oil.

Oil Formation Volume Factor (B_o): The oil formation factor, B_o, is defined as the ratio of the volume of oil (plus the gas in solution) at the prevailing reservoir pressure and temperature, to the volume of oil at standard conditions. Obviously the oil formation volume factor is always greater than or equal to one. Mathematically we can express the oil formation volume factor as:

$$B_o = \frac{V_{rc}}{V_{sc}} \quad (8.14)$$

Where:

B_o	= oil formation volume factor (rb/stb or m^3/Sm^3)
V_{rc}	= volume of oil at reservoir conditions (rb or m^3)
V_{sc}	= volume of at standard conditions (stb or Sm^3)

Values of oil FVF at reservoir temperature and various reservoir pressures can be obtained from a standard PVT analysis of a reservoir fluid sample. However, if this data is unavailable, the geologist/engineer must then resort to empirical correlations, **such as Standing[151], Vasquez and Beggs[152], or Glasø[153]. Generally Bo ranges from a low of 1.05 for heavy oils to a high of 2.5 rb/stb GOR volatile oils. Care should be exercised when applying any of the aforementioned correlations, as there is significant variation between the various correlations. In general, a given correlation may be more appropriate for a geological basin based on comparing actual measured PVT data from other fields with the correlation predicted results.**

Oil Isothermal Compressibility: The oil isothermal compressibility is defined as the rate of change in volume with pressure increase per unit volume of liquid, all variables other than pressure being constant. Thus, by definition, isothermal compressibility of a substance is defined mathematically by the following expression:

[151] *Standing, M. B.: "A Pressure-Volume-Temperature Correlation for Mixtures of California Oils and Gases", Drill, and Prod. Prac., API (1947).*

[152] *Vasquez M. and Beggs H. D.: "Correlations for Fluid Physical Property Prediction", J. Pet. Tech. (June 1980).*

[153] *Glasø, O.: "Generalized Pressure-Volume-Temperature Correlations", J.Pet.Tech. (May 1980).*

$$c_o = -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_T \tag{8.15}$$

Where:

c_o	=	oil isothermal compressibility (1/kPa).
V	=	oil volume (m^3).
P	=	pressure (kPa).

or in terms of oil formation volume factor we can derive;

$$c_o = -\frac{1}{B_o}\frac{dB_o}{dP} \tag{8.16}$$

Where:

c_o	=	oil compressibility (1/kPa).
B_o	=	oil formation volume factor (m^3/Sm^3).

Generally, isothermal compressibility is determined from a laboratory PVT study, in cases where a study has not been performed the correlations of Vasquez and Beggs[154] or Ramey[155] may be used.

Oil Viscosity (μ_o): Crude oil viscosity is an important physical property that controls and influences the flow of oil through porous media and pipes. The viscosity, in general, is defined as the internal resistance of the fluid to flow, and oil viscosity is a strong function of the temperature, pressure, oil gravity, gas gravity, and gas solubility. Oil viscosity can be classified into three main groups, based on the nature or state of the crude with respect to pressure, these are:

- Dead Oil Viscosity — The dead oil viscosity is defined as the viscosity of the oil at atmospheric pressure and temperature conditions (no gas in solution).
- Saturated Oil Viscosity — The saturated (bubble point) oil viscosity is defined as the viscosity of oil at the bubble point pressure and reservoir temperature.
- Undersaturated Oil Viscosity — The undersaturated oil viscosity is defined as the viscosity of the oil at a pressure above the bubble point and at reservoir temperature.

Whenever possible, oil viscosity should be determined in the laboratory at reservoir conditions, and is normally included in a standard PVT analysis of the crude. However, if no data is available, the correlations of Beggs and Robinson[156] and Andrade-Guzman-Reynolds[157] may be employed.

Water Fluid Properties

Water fluid properties are similar to the oil fluid properties, and include:

Water Density (ρw): Water density as the same definition as oil density, equation (8.7), with units of lbm/ft^3, kg/m^3, and g/cm$_3$. Fresh water density at 14.7 psia and 60 °F is 62.4 lb/ft^3, and for SI units at 101. 3 kpa and 15 °C, the density is 1000 kg/m^3. Note that density is quoted in various units even within a given unit system. In oilfield (English) units it is quite common to quote density as a gradient that is psi/ft. when laboratory data or actual water samples are unavailable. The density of formation water at reservoir conditions can be estimated roughly (usually to within +/−10%) from correlations such as McCain's[158] and [159] correlations.

Water Formation Volume Factor (Bw): The water formation volume factor has the same definition as for the oil formation volume factor. Normally this property is estimated from correlations based on salt content, for example the Numbere et al[160] correlation.

Water Viscosity (μw): Again, the definition is the same as for oil and is normally estimated from correlations based on salt content, for example by the Meehan[161]

8.2.2 CLASSIFICATION OF RESERVOIRS BY FLUID TYPE

Reservoir classification by fluid type includes the following reservoir fluids:

- Low Shrinkage Oil Reservoirs.
- High Shrinkage Oil Reservoirs.
- Volatile Oil Reservoirs.
- Dry Gas Reservoirs.
- Wet Gas Reservoirs.
- Retrograde Condensate Gas Reservoirs.

The following sections briefly outline the various reservoir types based on their fluid properties.

[161] *Meehan, D. N., "Estimating Water Viscosity at Reservoir Conditions", Petroleum Engineer, July 1980.*

Low Shrinkage Oil Reservoirs

The phase diagram for a typical low shrinkage oil is shown in Figure 8.2 (after Clark[162]), in this case the two-phase region covers a wide range of pressure and temperature (the critical temperature is above the reservoir temperature). The line marked 1 and 2 shows the effect of pressure reduction, with constant reservoir temperature, as the reservoir is produced. The dashed line shows the conditions encountered as the fluid travels up the tubing string and into the surface facilities.

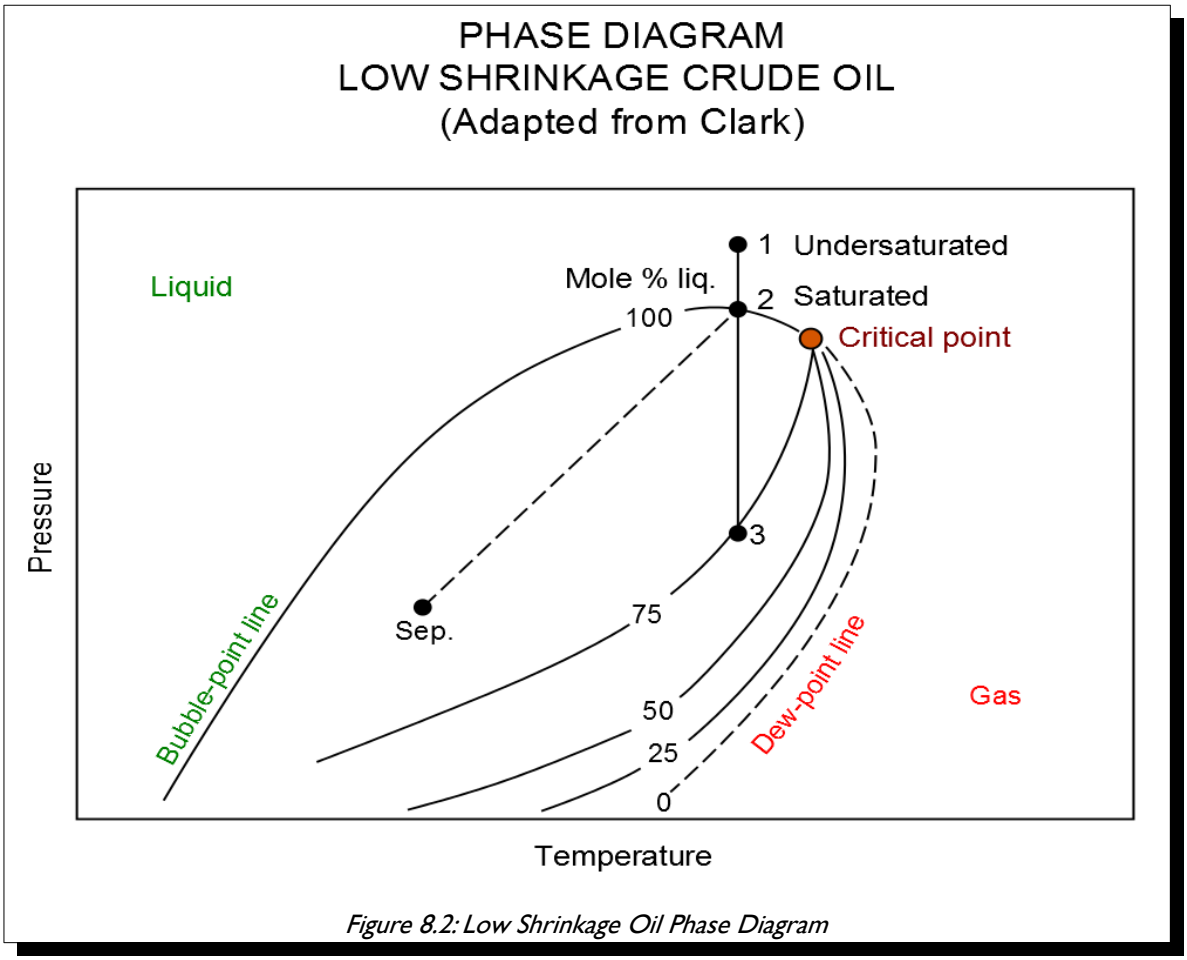

Figure 8.2: Low Shrinkage Oil Phase Diagram

If the reservoir pressure and temperature is at point 2 on the phase diagram, then the oil is at bubble point pressure and is said to be saturated, i.e., the oil contains the maximum amount of dissolved gas at the given conditions. However, if the reservoir conditions are at point 1 on the phase diagram, then the oil is said to be undersaturated. That is the oil is able to dissolve more gas at the current reservoir pressure and temperature.

The term low shrinkage oil, is derived from the fact that oil shrinkage is small, i.e., with an oil formation volume factors less than 1.5. This oil can be described as having a broad based phase envelope, high percentage of liquid, high proportion of heavier hydrocarbons, GOR's less than 500 scf/stb or 100 Sm^3/m^3, oil gravity 30 °API or heavier, and the stock tank liquid being black or a deep color. If the oil has a very low GOR and therefore has an oil formation volumes factor close to one, for as observed in heavy oil reservoirs, then it common to model this type of reservoir neglecting the gas phase. That is these type of reservoir fluids are typical modeled as two-phase oil-water system in black-oil formulations, which results in greater computational efficient due to having only two phases as oppose to three phases in an oil-gas-water system.

[162] *Clark, Norman, "It Pays to Know Your Petroleum", World Oil, March and April, 1953.*

High Shrinkage Oil Reservoirs

A high shrinkage oil reservoir fluid's phase diagram is shown in Figure 8.3.

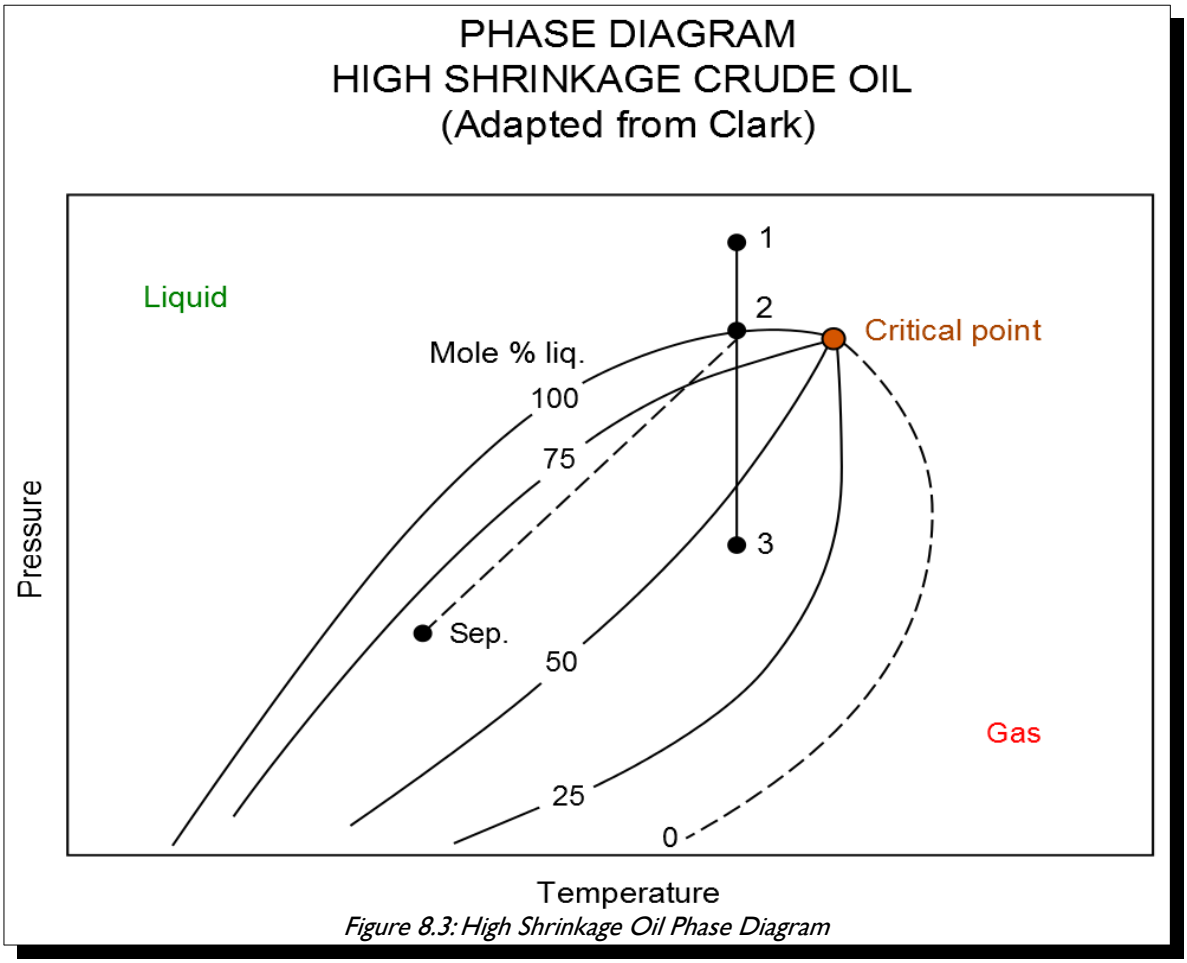

Figure 8.3: High Shrinkage Oil Phase Diagram

This type of reservoir fluid is characterized by not so broad a phase envelope, fewer heavier hydrocarbons, deep colored stock tank fluid, gravity less than 50 °API, GOR less than 8000 scf/stb or 1500 Sm^3/m^3, and oil formation volume factors greater than 1.5 Sm^3/m^3.

Dry Gas Reservoirs

Natural gas that occurs in the absence of condensate or liquid hydrocarbons, or gas that had condensable hydrocarbons removed, is called dry gas. It is primarily methane with some intermediates. The hydrocarbon mixture is solely gas in the reservoir and there is no liquid (condensate surface liquid) formed either in the reservoir or at surface.

The phase diagram for a dry gas reservoir is illustrated in Figure 8.4.

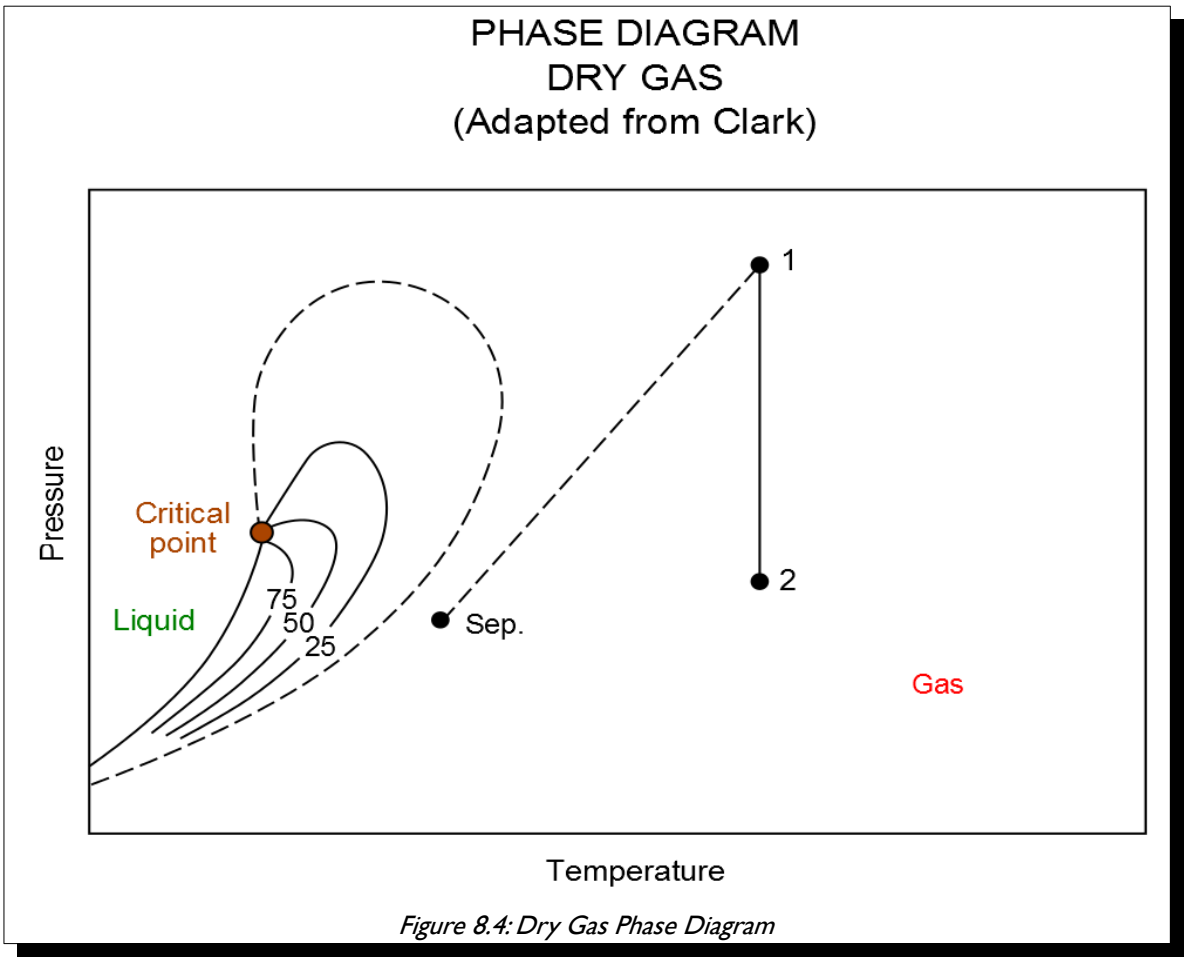

Figure 8.4: Dry Gas Phase Diagram

Notice that the separator conditions lie outside the phase envelope in the gas region. The term dry indicates that the gas does not contain heavier hydrocarbons to form liquids at the surface conditions. Dry gas typically has GOR's greater than 100,000 scf/stb or 18,000 Sm^3/m^3.

These type of reservoir fluids are typically modeled as two-phase gas-water systems in black-oil formulations, which results in greater computational efficient due to having only two phases as oppose to three phases in an oil-gas-water system. Also it is not uncommon to model dry gas reservoirs using analytical models, for example material balance, as in general the reservoirs behave like "tanks" either with or without aquifer influx.

Wet Gas Reservoirs

Natural gas that contains significant heavy hydrocarbons such as propane, butane and other liquid hydrocarbons is known as wet gas or rich gas. The general rule of thumb is if the gas contains less methane (typically less than 85% methane) and more ethane, and other more complex hydrocarbons, it is labelled as wet gas.

As can be seen from the figure below, wet gas exists in the gas phase in the reservoir throughout depletion of the reservoir pressure. However, the separator conditions lie in the two-phase region, resulting in liquid production (condensate).

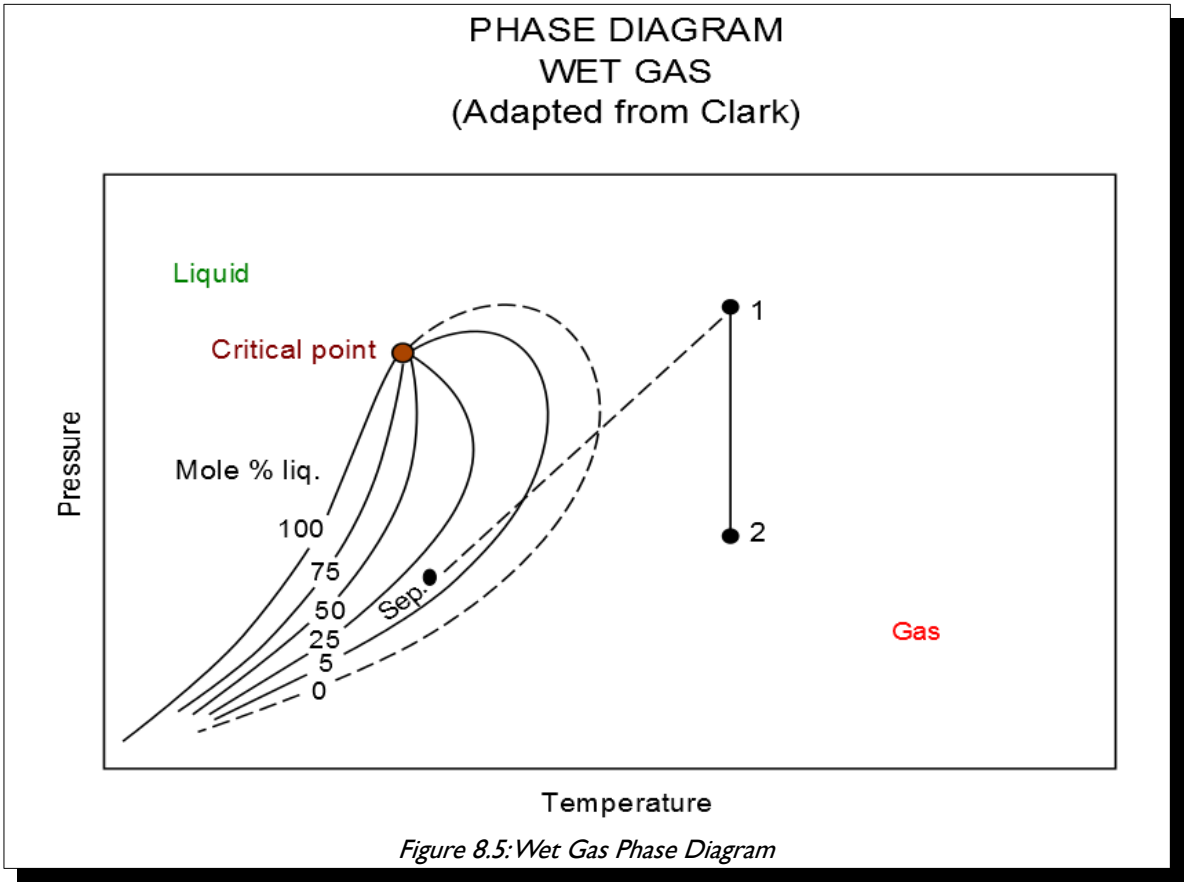

Figure 8.5: Wet Gas Phase Diagram

Wet gas normally has GOR's less than 100,000 scf/stb or 18,000 Sm^3/m^3, with the condensate having a gravity greater than 50 °API.

Retrograde Condensate Gas Reservoirs

If the reservoir temperature lies between the critical point and the cricondentherm a retrograde reservoir exists. As the pressure declines to point 2, which is the dew point, liquids begin to form in the reservoir. As the pressure further declines to point 3, the liquid yield increases. Further reduction in the pressure causes the liquid to vaporize back into the gas phase.

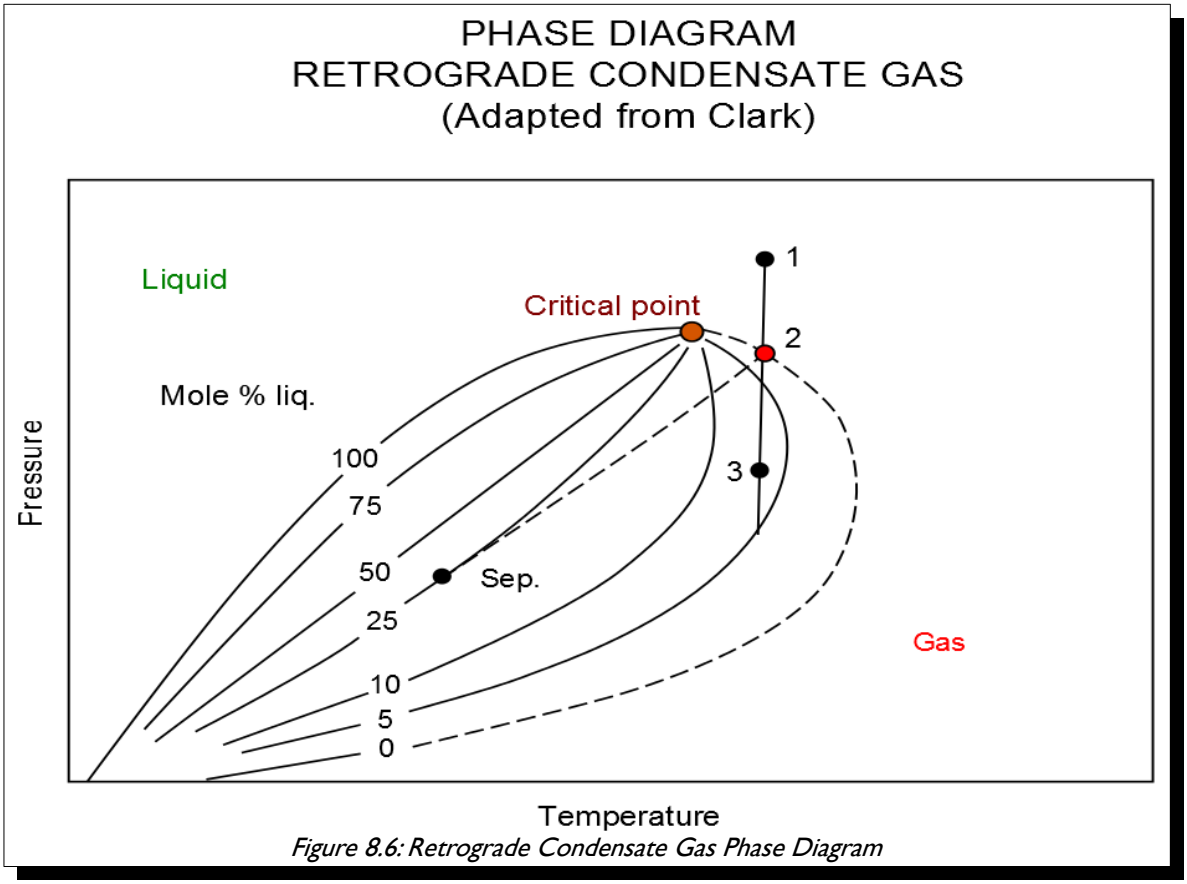

Figure 8.6: Retrograde Condensate Gas Phase Diagram

The liquid drop out in the reservoir can cause a well's productivity to be reduced, due to the system moving from a two-phase relative permeability effect, to a three phase effect. This is normally diagnosed by the well having a high skin factor.

This type of fluid has more lighter hydrocarbons than high shrinkage oils, and fewer heavier hydrocarbons than high shrinkage oils. The gravity can be as high as 60 °API, with GOR's up to 70,000 scf/stb or 13,000 Sm^3/m^3. Generally the stock tank liquid is water-white, or slightly colored.

Reservoir Classification

The following tables outline some general parameters used to classify reservoir fluids. Table 8.1 outlines some general producing characteristics used to define reservoir fluids.

Item	Crude Oil	Volatile Oil	Gas Condensate	Gas
Initial Separator Gas-Liquid Ratio, SCF/STB	<2000	2000 - 6000	6000 - 100,000 Generally 7,000 – 15,000	> 100,000 Usually below 3000,00
Color of Produced Liquid	Black to Light Green	Dark Straw Colored	Colorless to Light Straw Colored	Colorless
Usual API Gravity Range of Produced Fluid	10-45+	40-50	45-65	--
Composition of Produced Fluid	C_{7+}: usually > 40%	C_{7+}: 10-40%	C_{7+}: 2-10%	Primarily Methane
Oil Formation Volume Factor, RB/STB	< 2.0 frequently < 1.5	>2.0 often > 2.5		

Table 8.1: General Reservoir Fluid Classification

In terms of of fluid composition reservoir fluids can be indicated by the values shown in Table 8.2 below.

Item	Gas	Gas Condensate	Volatile Oil	Crude Oil
Methane (mole%)	96	87	64	49
Ethane (mole %0	3	4	8	3
Heptanes Plus (mole %)	1	3	15	42
Solution GOR (scf/stb)	105,000	18,200	2,000	625
Stock Tank Oil °API	68	61	50	34

Table 8.2: Reservoir Fluids Composition Indicators

in addition reservoir oil is further divided into Light, Medium, Heavy, Extra Heavy and Bituman (Wilmon[163]) as shown in Table 8.3 below:

Temperatue	STOCK TANK OIL °API	In Situ Viscosity (cp)
Light	>31.1	
Medium	22.3 – 31.1	
Heavy	10.0 – 22.3	100 to 10,000
Extra Heavy	<10.0	<10,000
Bitumen	<10.0	>10,000

Table 8.3: Oil Sub-Classification (after Wilmon)

[163] *Wilmon, G. J. : "Economic Outlook for Extra-heavy Oils, Natural Bitumens and Shale Oils", World Petroleum Congress (1987).*

8.2.3 FLUID PROPERTY TABLES

Table 8.4 outlines the oil, gas and water fluid types that can be active in the model, together with the related RUNSPEC section keywords that activate the phases, versus the PVT keywords that can be used to define the PVT behavior. The table also includes several water types, the standard water phase used in most simulations models, the Brine water phase used in the Brine Tracking model to track the flow of brine through the simulation grid and the effect of brine on reservoir performance, and finally OPM Flow's Vaporized Water phase that is used in the simulator's Salt Precipitation model. The latter water phase is not available in the commercial simulator.

Fluid Property Keywords Versus Oil, Gas & Water Fluid Types								
Item	**Oil**		**Gas**				**Water**	
Fluid Type	**Dead Oil**	**Live Oil**	**Dry Gas**	**Wet Gas**	**Dry / Wet Gas with Vaporized Water**	**CO_2 (EOR)**	**Water**	**Brine**
RUNSPEC Keywords	OIL	OIL	GAS	GAS	GAS	GAS	WATER	WATER
		DISGAS		VAPOIL	None/ VAPOIL			
					VAPWAT5			
					WATER			
					BRINE			BRINE
Pressure Dependent PVT	PVCDO	PVCO	PVDG	PVTG	PVTWSALT	PVTSOL	PVTW	PVTWSALT
	PVDO	PVTO	PVZG		PVTGW5	PVTDS		
					PVTGWO5			
Miscellaneous	RSCONST		RVCONST		RWGSALT5			
	RSCONSTT		RVCONSTT					
Surface Density	DENSITY				BDENSITY		DENSITY	BDENSITY
	GRAVITY						GRAVITY	

Notes:

1) Cells colored in gray with no mnemonic indicate that there is no keyword for this combination.
2) Cells colored orange show keywords that have not been implemented in OPM Flow for the given fluid type.
3) When two or more keywords are stated for the RUNSPEC keyword for a given fluid type, then all are required to define the given phase.
4) When two keywords are stated for the Pressure Dependent PVT and Miscellaneous data for a given fluid type, then either one can be used to define the PVT behavior for the given phase.
5) OPM Flow specific keywords.

Table 8.4: Fluid Property Keywords versus Oil, Gas and Water Fluid Type

For the Dead Oil phases the RSCONST and RSCONSTT keywords are used to set a constant gas-oil ratio (Rs). In this case the Rs is independent of the reservoir pressure and Rs is also negligible, as in for example heavy oil type fluids.

Similarly for the Dry Gas phase, where the RVCONST and RVCONSTT keywords are used to set a condensate-gas ratio (Rv) which is independent of the reservoir pressure and is also negligible, as in for example dry gas type fluids.

For the Vaporized Water phase and model, both dry and wet gas can be incorporated. Note that the PVTGW, PVTGWO, RWGSALT, and VAPWAT keywords are OPM Flow specific keywords.

In addition for the Brine phase, then either the SALT or SALTVD keywords in the SOLUTION section should be used to define the initial equilibration salt concentration for the model.

CO_2 can either be used as Enhanced Oil Recovery ("EOR") fluid by injecting the CO2 into an oil reservoir, or for modeling CO_2 storage. For the former, CO_2 is declared via the GAS keyword in the RUNSPEC and the PVT data is entered via the standard gas fluid properties for the hydrocarbon gas and either the PVTDS or the PVTSOL keywords are used to describe the interaction of the in situ oil and the injected CO_2.

In addition to the above the ROCK keyword should be used to define the rock compressibility. 7

Similarly, Table 8.5 outlines the fluid property data keywords for the CO2 storage, foam, polymer and solvent phases. Note that for these phases multiple keywords can be used to define the desired property behavior.

Fluid Property Keywords Versus CO2 (Storage), Foam, Polymer, Solvent, And MICP Fluid Types					
Fluid Type	**CO_2 (Storage)**	**Foam**	**Polymer**	**Solvent**	**MICP[7]**
RUNSPEC Keywords	CO2STORE	FOAM	POLYMER	SOLVENT	MICP
	GAS				WATER
	WATER				
Pressure Dependent PVT	Not required, calculated via correlations			PVDS	PVTW
				PVTSOL6	
Surface Density				SDENSITY	DENSITY
Miscellaneous	SALINITY5	FOAMADS	PLMIXPAR		MICPPARA
		FOAMDCYO	PLYADS		
		FOAMDCYW	PLYADSS		
		FOAMFCN	PLYATEMP		
		FOAMFRM	PLYCAMAX		
		FOAMFSC	PLYDHFLF		
		FOAMFSO	PLYESAL		
		FOAMFST	PLYKRRF		
		FOAMFSW	PLYMAX		
		FOAMMOB	PLYMWINJ8		
		FOAMMOBP	PLYRMDEN		
		FOAMMOBS	PLYROCK		
		FOAMOPTS	PLYSHEAR		

Fluid Property Keywords Versus CO2 (Storage), Foam, Polymer, Solvent, And MICP Fluid Types					
Fluid Type	**CO_2 (Storage)**	**Foam**	**Polymer**	**Solvent**	**MICP[7]**
		FOAMROCK	PLYSHLOG		
			PLYTRRF		
			PLYTRRFA		
			PLYVISC		
			PLYVISCS		
			PLYVISCT		
			PLYVMH8		
			PLYVSCST		
			SKPRPOLY8		
Miscellaneous			SKPRWAT8		

Notes:

1) Cells colored in gray with no mnemonic indicate that there is no keyword for this combination.
2) Cells colored orange show keywords that have not been implemented in OPM Flow.
3) When two or more keywords are stated for the RUNSPEC keyword for a given fluid type, then all are required to define the given phase.
4) When multiple keywords are stated for the Miscellaneous data for a given fluid type, then several keywords can be used to defined the fluid property behavior.
5) SALINITY is OPM Flow specific keyword, that defines the salinity for all cells in the model.
6) PVTSOL is used to model CO_2 interaction with in situ oil only and is an OPM Flow specific keyword.
7) OPM Flow's implementation of the Microbial Induced Calcite Precipitation ("MICP") model used to investigate CO_2 leakage remediation. All the keywords are specific to OPM Flow. This model also requires the ROCK keyword to define the rock compressibility.
8) OPM Flow has an additional formulation to the standard polymer flooding model, compared to the commercial simulator, known as the Polymer Molecular Weight Transport option, that uses the polymer molecular weight in calculating the polymer viscosity. This model is activated via the POLYMER and POLYMW keywords in the RUNSPEC section. The model does not account for non-Newtonian flow; the apparent viscosity is simply set equal to the zero-shear viscosity. Secondly, the standard polymer property data keywords: PLYROCK, PLYADS, PLYMAX, etc., are still required to fully describe the polymer fluid.

Table 8.5: Fluid Property Keywords versus CO2 (Storage), Foam, Polymer, Solvent, and MICP Fluid Types

As mentioned previously, CO2 can either be used as an EOR fluid by injecting the gas into an oil reservoir, or for modeling CO2 storage. For the latter, CO2 is declared via the GAS and CO2STORE keywords in the RUNSPEC section, and, except for the SALINITY keyword, all the remaining PVT data is calculated automatically via correlations by the simulator. A full description of the underlying PVT models is described by Sandve at al.[164]

Typical live oil and dry gas PVT data from the Volve[165] field is shown in Figure 8.7 and Figure 8.8, respectively. To fully define the live oil, dry gas, and water PVT properties for Volve the DENSITY, PVDG, PVTO, and PVTW keywords are employed.

[164] *Tor Harald Sandve1, Sarah E. Gasda, Atgeirr Rasmussen, and Alf Birger Rustad. Convective dissolution in field scale CO_2 storage simulation using the OPM Flow simulator. Submitted to TCCS 11 – Trondheim Conference on CO_2 Capture, Transport and Storage Trondheim, Norway – June 21-23, 2021.*

8.2.4 SATURATION TABLES (RELATIVE PERMEABILITY AND CAPILLARY PRESSURE TABLES)

Saturation tables contain the relative permeability and capillary pressure data as a function of fluid saturation and are used to both initialize the model and to describe multi-phase flow in the reservoir. Multiple saturation tables can be entered and allocated to various areas in the model, based on rock typing. Alternatively, a limited number of saturation tables may be entered and allocated by region and combined with end-point scaling option to enable a more robust reservoir rock characterization.

Note

Confusion abounds with the terms: critical water saturation, connate water saturation, and irreducible water saturation definitions, as the terms are extensively used interchangeably to define the maximum water saturation at which the water phase will remain immobile. For reference:

Connate Water Saturation: Water trapped in the interstices of the sediments at the time of deposition, as opposed to water that migrated into the formations after deposition[166]. Normally the nomenclature of S_{wc} is used to describe this type of water saturation.

Irreducible Water Saturation: The fraction of the pore volume occupied by water in a reservoir at maximum hydrocarbon saturation. It represents water that has not been displaced by hydrocarbons because it is trapped by adhering to rock surfaces, trapped in small pore spaces and narrow interstices, etc. Irreducible water saturation is an equilibrium situation. It differs from residual water saturation, the value measured by core analysis, because of filtrate invasion and the gas expansion that occurs when a core is removed from the bottom of the hole to the surface. Also called immovable water[167]. Here the nomenclature for irreducible water saturation is $S_{wirr.}$

Critical Water Saturation: Defines the largest water saturation for which the water relative permeability is zero.

In addition to the above definitions, the simulator uses the term SWL, which is lowest water saturation in a relative permeability table. Thus, SWL can represent either the connate water saturation or the irreducible water saturation in the relative permeability tables and functions.

Secondly, the term irreducible water saturation is replaced by term critical water saturation in the relative permeability tables and function, as both terms are equivalent with regards to the mobility of the water phase. This terminology is also consistent with the critical values of the oil and gas phases, which are dependent on the displacing phase.

Thirdly, it is not uncommon for SWL to be set equal to the critical water saturation; however, care should be taken in this instance if end-point scaling is being used to ensure that the cell scaled relative permeability curves are as one might expect.

A typical oil-water relative permeability set of curves is shown in Figure 8.9 indicating the oil end-point data (KRO, KRORW and (1 – SOWCR)) and the water end-point data (KRWR, KRW. SWL and SWCR).

[166] *https://wiki.seg.org/wiki/Dictionary:Connate_water*

[167] *https://wiki.seg.org/wiki/Dictionary:Irreducible_water_saturation*

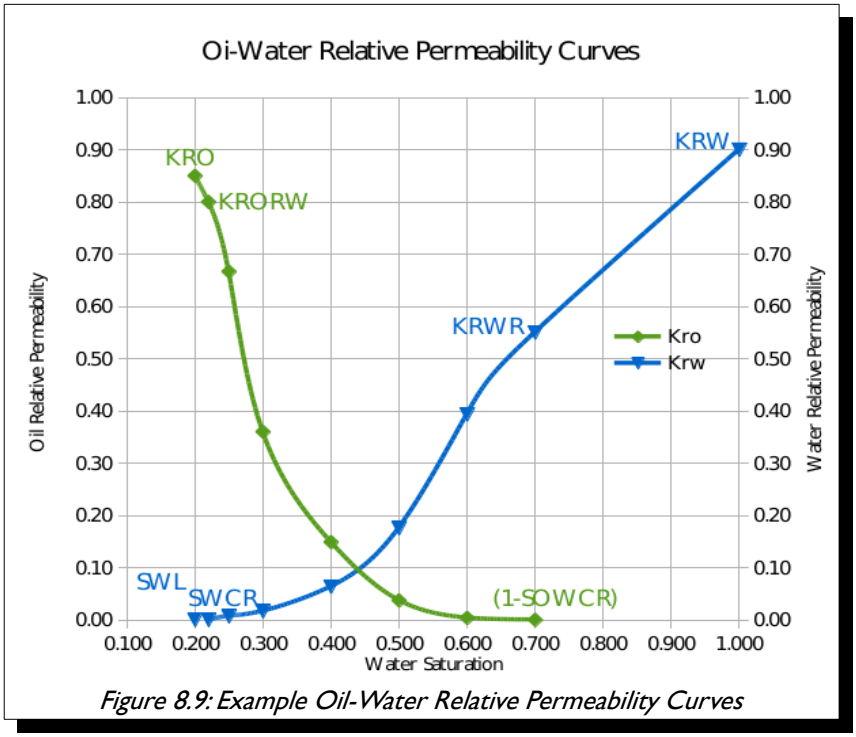

Figure 8.9: Example Oil-Water Relative Permeability Curves

The associated oil-water end-point definitions are outlined in the following table:

Type	End-Point Keyword	Oil-Water End-Point Definitions
Saturation	SOWCR	Critical oil-in-water saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-water system.
	SWL	Connate water saturation, that is the smallest water saturation in a water saturation function table.
	SWCR	Critical water saturation, that is the largest water saturation for which the water relative permeability is zero.
	SWU	Maximum water saturation in a water saturation table. This is commonly set equal to one, unless there is a residual oil saturation below the defined OWC.
Relative Permeability	KRO	Relative permeability of oil at the maximum oil saturation.
	KRORW	Relative permeability of oil at the critical water saturation
	KRW	Relative permeability of water at the maximum water saturation (normally the maximum water saturation is one).
	KRWR	Relative permeability of water at the residual oil saturation or the residual gas saturation in a gas-water run.
Capillary Pressure	SWLPC	Capillary pressure connate water saturation, that is the smallest water saturation in a water saturation function table to be scaled independently from the SWL relative permeability end-point value.

Table 8.6: Oil-Water Relative Permeability End-Point Data Definitions

Similarly for gas-oil systems, Figure 8.10 illustrates a typical gas-oil relative permeability set of curves indicating the oil end-point data (KRORG and (1 – SOGCR)) and the gas end-point data (KRGR, KRG and SGCR).

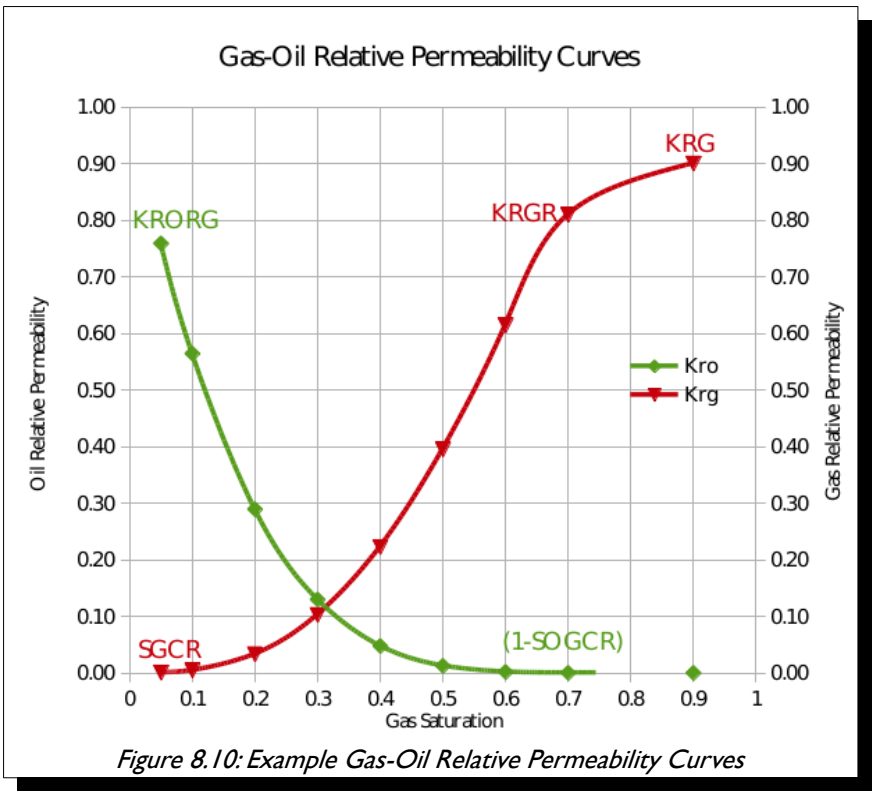

Figure 8.10: Example Gas-Oil Relative Permeability Curves

The gas-oil end-point definitions are outlined in the following table:

Type	End-Point Keyword	Gas-Oil End-Point Definitions
Saturation	SGCR	Critical gas saturation, that is the largest gas saturation for which the gas relative permeability is zero.
	SGL	Connate gas saturation, that is the smallest gas saturation in a gas saturation function table.
	SOGCR	Critical oil-in-gas saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-gas-connate water system.
Relative Permeability	KRG	Relative permeability of gas at the maximum gas saturation.
	KRGR	Relative permeability of gas at the residual oil saturation or the critical water saturation in a gas-water run.
	KRORG	Relative permeability of oil at the critical gas saturation.
Capillary Pressure	SGLPC	Capillary pressure connate gas saturation, that is the smallest gas saturation in a gas saturation function table to be scaled independently from the SGL relative permeability end-point value.

Table 8.7: Gas-Oil Relative Permeability End-Point Data Definitions

Finally, for two phase gas-water systems, Figure 8.11 illustrates a typical gas-water relative permeability set of curves indicating the gas end-point data (KRG, KRGR and (1 – SGWCR)) and the water end-point data (KRW, KRW, SWL and SWCR).

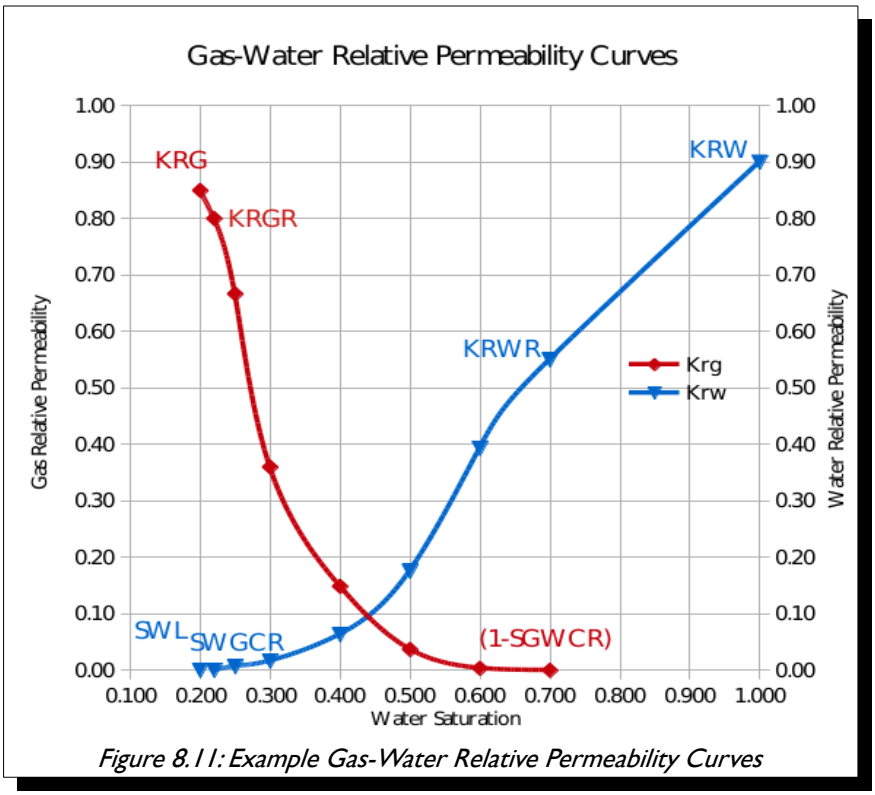

Figure 8.11: Example Gas-Water Relative Permeability Curves

The gas-oil end-point definitions are outlined in the following table:

Type	End-Point Keyword	Gas-Water End-Point Definitions
Saturation	SGL	Connate gas saturation, that is the smallest gas saturation in a water saturation function table.
	SGU	Maximum gas saturation in a gas saturation table.
	SGWCR	Critical gas-in-water saturation, that is the largest gas saturation for which the gas relative permeability is zero in a gas-water system.
	SWL	Connate water saturation, that is the smallest water saturation in a water saturation function table.
	SWCR	Critical water saturation, that is the largest water saturation for which the water relative permeability is zero.
	SWU	Maximum water saturation in a water saturation table.
Relative Permeability	KRG	Relative permeability of gas at the maximum gas saturation.
	KRGR	Relative permeability of gas at the residual oil saturation or the critical water saturation in a gas-water run.
	KRWR	Relative permeability of water at the residual oil saturation or the residual gas

Type	End-Point Keyword	Gas-Water End-Point Definitions
		saturation in a gas-water run.
Capillary Pressure	SWLPC	Capillary pressure connate water saturation, that is the smallest water saturation in a water saturation function table to be scaled independently from the SWL relative permeability end-point value.

Table 8.8: Gas-Water Relative Permeability End-Point Data Definitions

End-point scaling is activated in the RUNSPEC section with the ENDSCALE keyword and the data used to apply end-point scaling is entered in the PROPS section using the end-point keywords defined in Table 8.6 and Table 8.7 to define each grid block's end-point data. There is also direction dependent versions of the keywords for when directional end-point scaling has been activated. For example for critical water saturation, SWCR is used with non-direction end-point scaling and the SWCRX± , SWCRX± and SWCRX± series of keyword is used for when directional end-point scaling has been activated. In addition, there is also the facility to incorporate end-point scaling based on the drainage and / or imbibition process which again can be either non-directional or directional.

Note

If the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section, then the equivalent imbibition arrays suffixed with the letter I, for example IKRORW, can be used to define the KRORW for the relative permeability imbibition tables.

Consequently, if the hysteresis model option has not been activated, then the standard keywords are used to define the end-point scaling parameters, that is KRORW should be used and not IKRORW, even though this is usually considered an imbibition process with the wetting phase (normally water) increasing.

Saturation functions can be entered via several keywords consisting of two format types as depicted in the following table:

Format Type One				Format Type Two			
Keyword	**Oil**	**Gas**	**Water**	**Keyword**	**Oil**	**Gas**	**Water**
SGOF	Pcog			SGFN3		Pcog	
SLGOF	Pcog			SGWFN		Pcgw	
SWOF	Pcwo		Pcwo	SOF24	No Pc		
				SOF35	No Pc		
				SOF32D	No Pc		
				SWFN			Pcwo
OPM Flow LET[6]				**Format Type Three7**			
Keyword	**Oil**	**Gas**	**Water**	**Keyword**	**Oil**	**Gas**	**Water**
SGOFLET	Pcog			GSF		Pcgw	
SWGFLET		Pcgw		WSF			No Pc

OPM Flow LET[6]				Format Type Three7			
Keyword	**Oil**	**Gas**	**Water**	**Keyword**	**Oil**	**Gas**	**Water**
SWOFLET	Pcwo		Pcwo				

Notes:

1) Cells colored in gray with no mnemonic indicate that there is no keyword for this combination.
2) Cells colored orange show keywords that have not been implemented in OPM Flow.
3) In gas-water systems, the gas-water Pcgw data should be entered on the SWFN keyword and the Pcog on the SGFN keyword should be set to zero.
4) The SOF2 keyword defines the relative permeability in oil-gas and oil-water runs only, and the miscible hydrocarbon in SOLVENT runs. This keyword should not be used to define the oil relative permeability when oil, gas and water are present.
5) Defines oil in relative with respect to water and oil relative permeability with respect gas.
6) OPM Flow specific keywords implement the LET family of saturation function, see Lomeland et al.[168].
7) Format Type Three keywords are available in the commercial compositional simulator only, and will cause an error if used in the commercial black-oil simulator.

Table 8.9: Saturation Table Formats and Phases

Note that only format type can be used in a run, that is one must either use format type one relative permeability keywords to define the required saturation functions, or format two. One cannot combine the keywords from the different format types in the same input deck.

Figure 8.12 shows an unscaled oil-water relative permeability curve from the Volve model, and Figure 8.13 displays the corresponding scaled relative permeability curves after applying the end-point scaling parameters. Similarly for the gas-oil curves, Figure 8.14 illustrates the unscaled curves and Figure 8.15 the scaled curves. The plots indicate that the end-point scaling has been applied correctly.

8.2.5 SATURATION TABLE GENERATION - COREY CURVES

As mentioned in the *2.4.1 Data Quality and Assurance* section, Corey relative permeability curves are often used to "smooth" the intended relative permeability curves to be used in the simulator in order to improve convergence.

Corey[169] combined the work of Purcell[170] and Burdine[171] that was widely accepted for its simplicity. His original equations were developed for the drainage cycle in water-wet sandstones, but have also been used in carbonate formations. Corey's original water-oil equations were as follows:

$$k_{ro}\left(S_w\right) = \left[\frac{1 - S_w}{1 - S_{wcr}}\right]^{n_o} \tag{8.17}$$

$$k_{rw}\left(S_w\right) = \left[\frac{S_w - S_{wcr}}{1 - S_{wcr}}\right]^{n_w} \tag{8.18}$$

Where:

$k_{ro}(S_w)$	= relative permeability to oil,
$k_{rw}(S_w)$	= relative permeability to water,
n_o	= Corey oil exponent, set to four in the original paper,
n_w	= Corey water exponent, set to four in the original paper,
S_w	= water saturation, and
S_{wc}	= critical water saturation.

The denominator in equations (8.17) and (8.18) scales the water saturation to the mobile water phase. There are several forms of these equations, with the most common normalizing the saturation over the mobile hydrocarbon phase, as depicted in equations (8.19) and (8.20).

$$k_{ro}\left(S_w\right) = k_{row}\left[\frac{1 - S_w - S_{orw}}{1 - S_{orw} - S_{wcr}}\right]^{n_o} \tag{8.19}$$

$$k_{rw}\left(S_w\right) = k_{rww}\left[\frac{S_w - S_{wc}}{1 - S_{orw} - S_{wcr}}\right]^{n_w} \tag{8.20}$$

Where,

k_{row}	= maximum oil relative permeability at Swc,
k_{rw}	= maximum water relative permeability st Sorw,
S_{wc}	= critical water saturation, and
S_{orw}	= residual oil saturation under a water flood (SOWCR).

Similar equations exist for gas-oil and water-oil systems. As mentioned above, the denominator in the equations, normalizes the saturation to the mobile phase, as a consequence, it is still necessary to extend the resulting Corey water curve to 100% water saturation in order to correctly model the water leg. In terms of the values for the various Corey exponents, Table 8.10 offers some guidelines based on the rock's wettability.

[169] *Corey, A. T.: "The Interrelation Between gas and Oil Relative Permeabilities", Production Mon., 19. 38. (1954).*

[170] *Purcell, W. R., "Capillary Pressures- Their Measurement Using Mercury and the Calculation of Permeability Therefrom", Transactions AIME, 186, 39 (1949).*

[171] *Burdine, N. T., "Relative Permeability Calculations from Pore Size Distribution Data", , Transactions AIME, 198, 71 (1953).*

Corey Guide (Water-Oil)			Corey Guide (Gas-Oil)		
Wettability	**Kro**	**Krw**	**Wettability**	**Kro**	**Krg**
Water wet	2 - 4	5 - 8	Water wet		
Intermediate	3 - 6	3 - 5	Intermediate		
Oil wet	6 - 8	2 - 3	Oil wet	4 - 8	2 - 4

Table 8.10: Corey Exponent Values

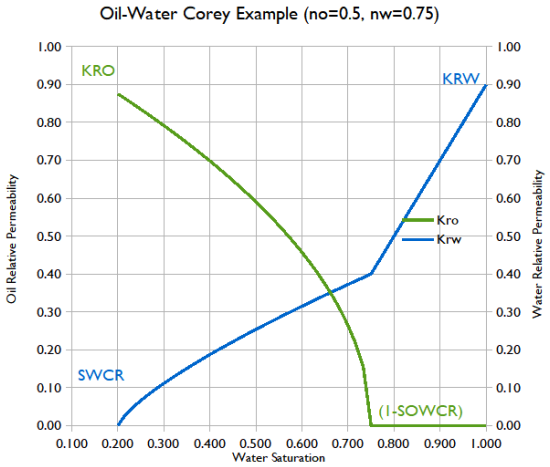

Figure 8.16: Oil-Water Corey Example (no=3.0, nw=4.0)

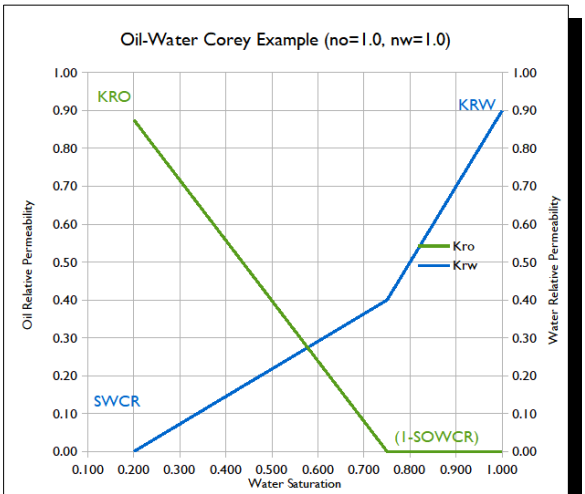

Figure 8.17: Oil-Water Corey Example (no=1.0, nw=1.0)

As can be seen in Figure 8.16 to Figure 8.18, the Corey exponents less than one result in a concave curve, and values great than one result in a convex curve, where as a value of one gives a straight line.

Unfortunately, neither OPM Flow nor the commercial simulator, unlike some other simulators, support the direct entry of Corey type curves, and thus Corey curves have to generated outside of the simulator. Fortunately, OPM Flow does support the more advance and flexible LET family of models instead, which are described in the next section.

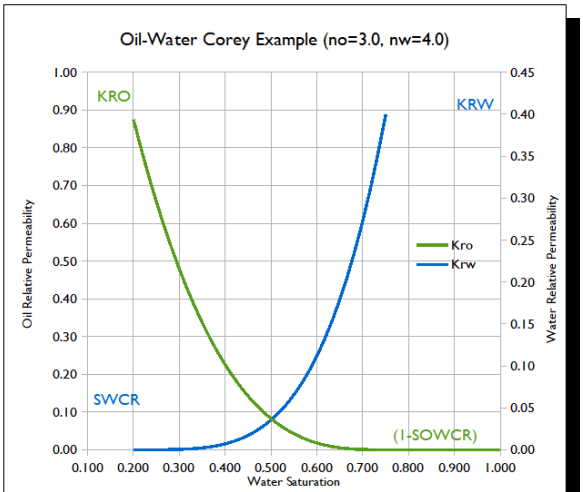

Figure 8.18:: Oil-Water Corey Example (no=3.0, nw=4.0)

8.2.6 SATURATION TABLE GENERATION - LET FUNCTIONS

OPM Flow has implemented the LET family of saturation functions, models, based on the work of Lomeland et al.[172,173,174 and 175,,] via the *SGOFLET– Gas-Oil LET Relative Permeability Functions*, *SGWFLET – Gas-Water LET Relative Permeability Functions*, and *SWOFLET – Water-Oil LET Relative Permeability Functions* keywords in this section. The keywords are used as replacements for the SGOF and SWOF keywords for three-phase oil-gas-water systems, and the SGWFN keyword for gas-water systems. Note there a two versions of the LET functions, LET[172] for two-phase flowing conditions and LETx[176] for three-phase flowing conditions. All three keywords implement the LET version for two phase systems.

The functions are dependent on the drainage and imbibition cycle of the wetting phase as well as drainage and inhibition cycle number, since a reservoir may undergo several flooding events. To account for this the system defines the flooding event using the three saturations: Sw, So, and Sg together with the state of the three saturations during the flooding event. The saturation state can be Increasing, Decreasing, or Constant, for a given flooding event cycle number (n). Thus, Sw(D), So(I), Sg(C)1or DIC1, means the water phase is decreasing, the oil phase is increasing and the gas phase is constant for the primary or first cycle (n equals one). This is case for when oil is migrating into the reservoir rock and displacing the initial water contained with the reservoir. The various flooding processes are outlined in Table 8.11

Modeling Of Flooding Processes				
Oil Field		Gas Field		Comment
Oil-Water Oil Leg	Oil-Gas Oil-Leg	Gas-Water Gas Cap	Oil-Gas Gas Cap	Nomenclature LET(Sw, So, Sg, n)
DIC1	CDI2	DCI1	CDI2	Primary starting point.
IDC2	CID3	ICD2	CID3	Second event
DIC3	CID4	DCI3	CID4	Third event

Table 8.11: LET Modeling of Flooding Processes

Thus, DIC1 is the well-known primary (first inflow number) drainage for an oil/water system, and IDC2 is the well-known (second general inflow number) imbibition for an oil/water system.

The following section describe the various flooding scenarios and the standard LET equations used in the literature.

[176] *Lomeland F. and Ebeltoft E., 2013. Versatile Three-phase Correlations for Relative Permeability and Capillary Pressure. Paper SCA2013-034 presented at the International Symposium of the Society of Core Analysts held in Napa Valley, California, USA, 16-19 September, 2013.*

Oil Displacing Water: Primary Drainage Cycle (DIC1)

For the Primary Drainage, assuming water is the wetting phase, then, Sw(D), So(I), Sg(C)1or DIC1, means the water phase is decreasing, the oil phase is increasing and the gas phase is constant for the primary or first cycle (n equals one). This is case for when oil is migrating into the reservoir rock and displacing the initial water contained within the reservoir. Under these circumstance the LET normalize water saturation and relative permeability functions are defined as:

$$K_{row} = \frac{K_{rot}\left(1 - S_{wp}\right)^{L_o}}{\left(1 - S_{wp}\right)^{L_o} + E_o S_{wp}^{T_o}} \tag{8.21}$$

$$K_{rw} = \frac{K_{rwt} S_{wp}^{L_w}}{S_{wp}^{L_w} + E_w\left(1 - S_{wp}\right)^{T_w}} \tag{8.22}$$

$$S_{wp} = \frac{S_w - S_{wirr}}{1 - S_{wirr}} \tag{8.23}$$

Where:

E_α	=	empirical E parameter for the α phase,
K_{row}	=	oil relative permeability with respect to water saturation,
K_{rot}	=	base or top oil relative permeability, used to scale the maximum oil permeability,
K_{rw}	=	water relative permeability,
K_{rwt}	=	base or top water relative permeability, used to scale the maximum water permeability,
L_α	=	empirical L parameter for the α phase,
T_α	=	empirical T parameter for the α phase,
S_w	=	water saturation,
S_{wirr}	=	irreducible water saturation, and
S_{wp}	=	normalize water saturation.

The LET empirical parameters: E, L and T, influence the shape of the relative permeability curves, as depicted in Figure 8.19

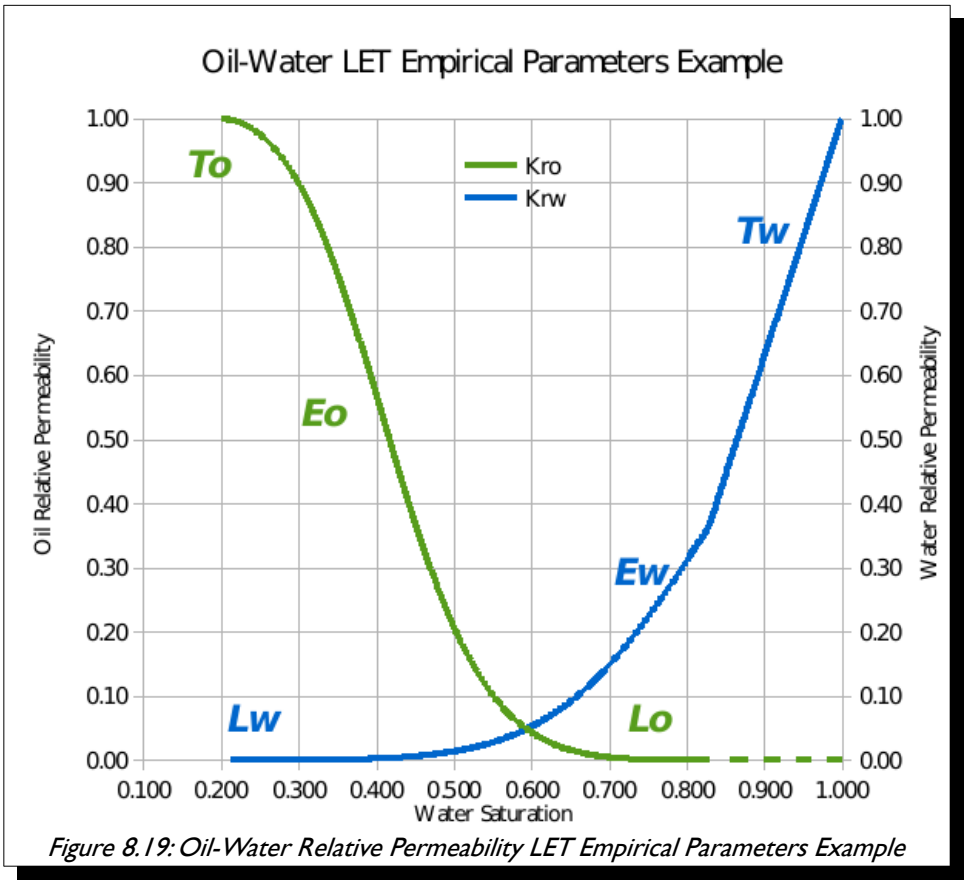

Figure 8.19: Oil-Water Relative Permeability LET Empirical Parameters Example

For the for the primary drainage or first cycle, DIC1, with the water phase decreasing, the oil phase increasing and the gas phase constant, the LET capillary pressure functions are:

$$Y = \frac{P_{cow} - P_{ct}}{P_{cir} - P_{ct}} \quad and \quad Y = F\left(S_{wp}\right) \quad where \quad S_{wirr} \leqslant S_w \leqslant 1.0 \tag{8.24}$$

$$P_{cow}\left(S_w = S_{wirr}\right) = P_{cir} \quad and \quad P_{cow}\left(S_w = 1.0\right) = P_{cit} \tag{8.25}$$

$$F = \frac{\left(1 - S_{wp}\right)^L}{\left(1 - S_{wp}\right)^L + E\,S_{wp}^T} \quad and \quad S_{wp} = \frac{S_w - S_{wirr}}{1 - S_{wirr}} \tag{8.26}$$

Where:

E	=	empirical E parameter,
L	=	empirical L parameter,
P_{cir}	=	capillary pressure at irreducible water saturation,
P_{ct}	=	capillary threshold / entry pressure,
T	=	empirical T parameter,
S_w	=	water saturation,
S_{wirr}	=	irreducible water saturation, and
S_{wp}	=	normalize water saturation.

The capillary pressure LET functions with either L or T equal to one are called a semi-simple LET functions, and LET functions with both L and T equal to one are called a simple LET function. The simple LET function is equal to the Pc correlation of Honapour et al.[177] except for the arrangement of the empirical coefficients.

The L parameter describes the lower part of the curve, whereas the T parameter describes the top part of the curve in a similar to how the L parameter describes the lower part of the curve. Finally, the E parameter describes the position of the slope of the curve, that is the elevation. An E value of one is neutral, and the position of the slope is governed by the L and T parameters in this case. Whereas, increasing the value of the E moves the slope towards the high end of the curve, and decreasing the value of the E moves the slope towards the lower end of the curve. Lombard et al.173 note that experience using the LET correlation indicate that L, E, and T values should greater than or equal to 0.01, with no upper limit.

Figure 8.20 shows a typical LET derived drainage oil-water capillary pressure curve, and Figure 8.21 shows a typical imbibition curves, the later is discussed in the following section.

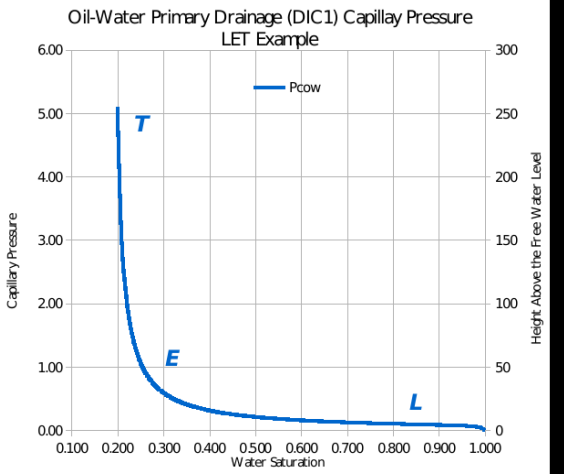

Figure 8.20: Oil-Water Primary Drainage (DIC1) Capillary Pressure LET Example

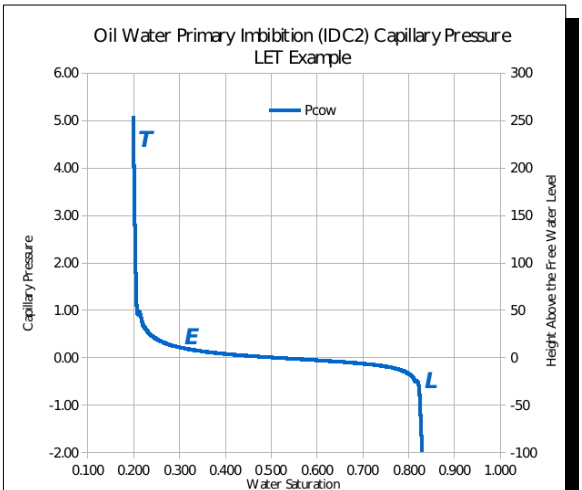

Figure 8.21: Oil Water Primary Imbibition (IDC2) Capillary Pressure LET Example

OPM has implemented a more restrictive form of the general LET functions, more akin to the original paper[172], as depicted in Figure 8.20. Table 8.12 relates the general LET equations presented previously with the parameters on the SWOFLET keyword.

LET Function (DIC1) versus SWOFLET Keyword					
SWOFLET	**LET Function**	**SWOFLET**	**LET Function**	**SWOFLET**	**LET Function**
SWL	S_{wirr}	SORW		PCIR	P_{cir}
SWCR	S_{wirr}	SOWCR		PCIT	P_{ct}

SWOFLET	**LET Function**	**SWOFLET**	**LET Function**	**SWOFLET**	**LET Function**
KRTWAT	K_{rwt}	KRTOIL	K_{rot}		

Notes:

1) The current implementation of the LET functions is restricted to a single branch capillary pressure curves as shown in Figure 8.20, and not the multi-branch curve shown in Figure 8.21.

Table 8.12: LET Functions (DIC1) versus SWOFLET Keyword

Water Displacing Oil: Primary Imbibition Cycle (IDC2)

Similarly for the oil producing phase, were the water phase is increasing either by replacing the displaced oil or via water injection, that is Sw(I), So(D), Sg(C), for the second flooding event, IDC2. Under this scenario the LET equations are:

$$K_{row} = \frac{K_{rot}\left(1 - S_{wn}\right)^{L_o}}{\left(1 - S_{wn}\right)^{L_o} + E_o S_{wn}^{T_o}} \tag{8.27}$$

$$K_{rw} = \frac{K_{rwr} S_{wn}^{L_w}}{S_{wn}^{L_w} + E_w\left(1 - S_{wn}\right)^{T_w}} \tag{8.28}$$

$$S_{wn} = \frac{S_w - S_{wirr}}{1 - S_{orw} - S_{wirr}} \tag{8.29}$$

Where:

E_α = empirical E parameter for the α phase,
K_{row} = oil relative permeability with respect to water saturation,
K_{rot} = base or top oil relative permeability, used to scale the maximum oil permeability,
K_{rw} = water relative permeability,
K_{rwr} = base or top water relative permeability, used to scale the maximum water permeability,
L_α = empirical L parameter for the α phase,
T_α = empirical T parameter for the α phase,
S_{orw} = residual oil saturation under water displacement,
S_w = water saturation,
S_{wirr} = irreducible water saturation, and
S_{wn} = normalize water saturation.

For the for the primary imbibition or second cycle, IDC2, with the water phase increasing, the oil phase decreasing and the gas phase constant, the LET capillary pressure functions are:

$$P_{cow} = \left(P_{cir} - P_{ct}\right)G_n + \left(P_{cor} - P_{ct}\right)F_n + P_{ct} \tag{8.30}$$

$$where\ S_{wir} \le S_w \le \left(1 - S_{orw}\right)\ and\ P_{cow}\left(S_w = S_{wzo}\right) = 0 \Rightarrow E_{sn}$$

$$G_n = \frac{\left(1 - S_{wn}\right)^{L_{sn}}}{\left(1 - S_{wn}\right)^{L_{sn}} + E_{sn} S_{wn}^{T_{sn}}} \qquad F_n = \frac{S_{wn}^{L_{fn}}}{S_{wn}^{L_{fn}} + E_{fn}\left(1 - S_{wn}\right)^{T_{fn}}} \tag{8.31}$$

$$S_{wn} = \frac{S_w - S_{wirr}}{1 - S_{orw} - S_{wirr}} \tag{8.32}$$

Where:

E_{fn} = forced imbibition empirical E parameter,
E_{sn} = spontaneous imbibition empirical E parameter,
L_{fn} = forced imbibition empirical L parameter,
L_{sn} = spontaneous imbibition empirical L parameter,
P_{cir} = capillary pressure at irreducible water saturation,
P_{ct} = capillary threshold / entry pressure,
T_{fn} = forced imbibition empirical T parameter,
T_{sn} = spontaneous imbibition empirical T parameter,
S_{orw} = residual oil saturation under water displacement,
S_w = water saturation,
S_{wirr} = irreducible water saturation, and
S_{wn} = normalize water saturation.

Spontaneous imbibition, refers to the wetting phase displacing the non-wetting phase, resulting in capillary pressure values greater than zero. For example, in a water wet oil reservoir under water drive, the water will easily imbibe into the pore space and displace the non-wetting oil phase. Forced imbibition is when the non-wetting phase displaces the wetting phase, and results in a negative capillary pressure values necessary to overcome the capillary force holding the wetting phase in-place. Thus, for a water wet oil reservoir, with the oil zone expanding into the water zone, an additional force is required to displace the water.

Table 8.13 relates the general LET equations presented previously with the parameters on the SWOFLET keyword.

LET Function (IDC2) versus SWOFLET Keyword					
SWOFLET	**LET Function**	**SWOFLET**	**LET Function**	**SWOFLET**	**LET Function**
SWL	S_{wirr}	SORW	S_{orw}	PCIR	P_{cir}
SWCR	S_{wirr}	SOWCR	S_{orw}	PCIT	P_{ct}
LWAT	L_w	LOIL	L_o	LPC	L_{sn}
EWAT	E_w	EOIL	E_o	EPC	E_{sn}
TWAT	T_w	TOIL	T_o	TPC	T_{sn}
KRTWAT	K_{rwr}	KRTOIL	K_{rot}		

Notes:

1) The current implementation of the LET functions is restricted to a single branch capillary pressure curves as shown in Figure 8.20, and not the multi-branch curve shown in Figure 8.21.

Table 8.13: LET Functions (IDC2) versus SWOFLET Keyword

Gas Displacing Oil: Primary Imbibition (CDI2)

For the oil producing phase, were the gas phase is increasing either by replacing the displaced oil or via gas injection, CDI2, the LET equations are:

$$K_{rog} = \frac{K_{rot}\left(1 - S_{gn}\right)^{L_o}}{\left(1 - S_{gn}\right)^{L_o} + E_o S_{gn}^{T_o}} \tag{8.33}$$

$$K_{rg} = \frac{K_{rgt} S_{gn}^{L_g}}{S_{gn}^{L_g} + E_g\left(1 - S_{gn}\right)^{T_g}} \tag{8.34}$$

$$S_{gn} = \frac{S_g}{1 - S_{org} - S_{wirr}} \tag{8.35}$$

Where:

E_α	=	empirical E parameter for the α phase,
K_{rog}	=	oil relative permeability with respect to gas saturation,
K_{rot}	=	base or top oil relative permeability, used to scale the maximum oil permeability,
K_{rg}	=	gas relative permeability,
K_{rgt}	=	base or top gas relative permeability, used to scale the maximum gas permeability,
L_α	=	empirical L parameter for the α phase,
T_α	=	empirical T parameter for the α phase,
S_g	=	gas saturation,
S_{gn}	=	normalize gas saturation,
S_{org}	=	residual oil saturation under gas displacement, and
S_{wirr}	=	irreducible water saturation.

Similarly for the for the capillary pressure CDI2, with the water phase constant, the oil phase decreasing and the gas phase increasing, the LET capillary pressure functions are:

$$P_{cog} = \left(P_{cir} - P_{ct}\right) G_n + \left(P_{cor} - P_{ct}\right) F_n + P_{ct} \tag{8.36}$$

$$where\ S_{wir} \le S_w \le \left(1 - S_{org} - S_{wirr}\right)\ and\ P_{cog}\left(S_w = S_{wzo}\right) = 0 \Rightarrow E_{sn}$$

$$G_n = \frac{\left(1 - S_{gn}\right)^{L_{sn}}}{\left(1 - S_{gn}\right)^{L_{sn}} + E_{sn} S_{gn}^{T_{sn}}} \qquad F_n = \frac{S_{gn}^{L_{fn}}}{S_{gn}^{L_{fn}} + E_{fn}\left(1 - S_{gn}\right)^{T_{fn}}} \tag{8.37}$$

$$S_{gn} = \frac{S_g}{1 - S_{org} - S_{wirr}} \tag{8.38}$$

Where:

E_{fn}	=	forced imbibition empirical E parameter,
E_{sn}	=	spontaneous imbibition empirical E parameter,

L_{fn} = forced imbibition empirical L parameter,
L_{sn} = spontaneous imbibition empirical L parameter,
P_{cir} = capillary pressure at irreducible water saturation,
P_{ct} = capillary threshold / entry pressure,
T_{fn} = forced imbibition empirical T parameter,
T_{sn} = spontaneous imbibition empirical T parameter,
S_g = gas saturation,
S_{gn} = normalize gas saturation,
S_{org} = residual oil saturation under gas displacement, and
S_{wirr} = irreducible water saturation.

Table 8.14 relates the general LET equations presented previously with the parameters on the SGOFLET keyword.

LET Function (CDI2) versus SGOFLET Keyword					
SGOFLET	**LET Function**	**SGOFLET**	**LET Function**	**SGOFLET**	**LET Function**
SGL		SORG	S_{org}	PCIR	P_{cir}
SGCR		SOGCR	S_{org}	PCIT	P_{ct}
LGAS	L_g	LOIL	L_o	LPC	L_{sn}
EGAS	E_g	EOIL	E_o	EPC	E_{sn}
TGAS	T_g	TOIL	T_o	TPC	T_{sn}
KRTGAS	K_{rgt}	KRTOIL	K_{rot}		

Notes:

1) The current implementation of the LET functions is restricted to a single branch capillary pressure curves as shown in Figure 8.20, and not the multi-branch curve shown in Figure 8.21.
2) The S_{wirr} parameter value is taken from the SWOFLET keyword.

Table 8.14: LET Functions (CDI2) versus SGOFLET Keyword

Gas Displacing Water: Primary Drainage Cycle (DCI1)

For the Primary Drainage, assuming water is the wetting phase, then, Sw(D), So(C), Sg(I)1or DCI1, means the water phase is decreasing, the oil phase is constant and the gas phase is increasing for the primary or first cycle (n equals one). This is case for when gas is migrating into the reservoir rock and displacing the initial water contained within the reservoir. Under these circumstance the LET normalize water saturation and relative permeability functions are defined as:

$$K_{rgw} = \frac{K_{rgt}\left(1 - S_{wp}\right)^{L_g}}{\left(1 - S_{wp}\right)^{L_g} + E_g S_{wp}{}^{T_g}} \tag{8.39}$$

$$K_{rw} = \frac{K_{rwt} S_{wp}^{L_w}}{S_{wp}^{L_w} + E_w\left(1 - S_{wp}\right)^{T_w}} \tag{8.40}$$

$$S_{wp} = \frac{S_w - S_{wirr}}{1 - S_{wirr}} \tag{8.41}$$

Where:

E_α = empirical E parameter for the α phase,
K_{rgw} = gas relative permeability with respect to water saturation,
K_{rgt} = base or top gas relative permeability, used to scale the maximum gas permeability,
K_{rw} = water relative permeability,
K_{rwt} = base or top water relative permeability, used to scale the maximum water permeability,
L_α = empirical L parameter for the α phase,
T_α = empirical T parameter for the α phase,
S_w = water saturation,
S_{wirr} = irreducible water saturation, and
S_{wp} = normalize water saturation.

For the for the primary drainage or first cycle, DCI1, with the water phase decreasing, the oil phase constant and the gas phase increasing, the LET capillary pressure functions are:

$$Y = \frac{P_{cgw} - P_{ct}}{P_{cir} - P_{ct}} \quad and \quad Y = F\left(S_{wp}\right) \quad where \quad S_{wirr} \leqslant S_w \leqslant 1.0 \tag{8.42}$$

$$P_{cgw}\left(S_w = S_{wirr}\right) = P_{cir} \quad and \quad P_{cgw}\left(S_w = 1.0\right) = P_{cit} \tag{8.43}$$

$$F = \frac{\left(1 - S_{wp}\right)^L}{\left(1 - S_{wp}\right)^L + E\,S_{wp}^T} \quad and \quad S_{wp} = \frac{S_w - S_{wirr}}{1 - S_{wirr}} \tag{8.44}$$

Where:

E = empirical E parameter,
L = empirical L parameter,
P_{cir} = capillary pressure at irreducible water saturation,
P_{ct} = capillary threshold / entry pressure,
T = empirical T parameter,
S_w = water saturation,
S_{wirr} = irreducible water saturation, and
S_{wp} = normalize water saturation.

Table 8.15 relates the general LET equations presented previously with the parameters on the SGOFLET keyword.

LET Function (DCI1) versus SGWFLET Keyword					
SGWFLET	**LET Function**	**SGWFLET**	**LET Function**	**SGWFLET**	**LET Function**
SGL		SWL	S_{wirr}	PCIR	P_{cir}

LET Function (DCI1) versus SGWFLET Keyword					
SGWFLET	**LET Function**	**SGWFLET**	**LET Function**	**SGWFLET**	**LET Function**
SGCR		SWCR	S_{wirr}	PCIT	P_{ct}
LGAS	L_g	LWAT	L_w	LPC	L

TGAS	T_g	TWAT	T_w	TPC	T
KRTGAS	K_{rgt}	KRTWAT	K_{rwr}		

Notes:

1) The current implementation of the LET functions is restricted to a single branch capillary pressure curves as shown in Figure 8.20, and not the multi-branch curve shown in Figure 8.21.

Table 8.15: LET Functions (DCI1) versus SGOFLET Keyword

Note

The SGWFLET keyword has not been implemented, as of this current release.

Water Displacing Gas: Primary Imbibition Cycle (ICD2)

Similarly for the gas producing phase, were the water phase is increasing either by replacing the displaced gas or via water influx from the aquifer, that is Sw(I), So(C), Sg(D), for the second flooding event, IDC2. Under this scenario the LET equations are:

$$K_{rgw} = \frac{K_{rgt}\left(1 - S_{wn}\right)^{L_o}}{\left(1 - S_{wn}\right)^{L_o} + E_o S_{wn}^{T_o}} \tag{8.45}$$

$$K_{rw} = \frac{K_{rwr} S_{wn}^{L_w}}{S_{wn}^{L_w} + E_w\left(1 - S_{wn}\right)^{T_w}} \tag{8.46}$$

$$S_{wn} = \frac{S_w - S_{wirr}}{1 - S_{grw} - S_{wirr}} \tag{8.47}$$

Where:

E_α = empirical E parameter for the α phase,
K_{rgw} = gas relative permeability with respect to water saturation,
K_{rot} = base or top gas relative permeability, used to scale the maximum gas permeability,
K_{rw} = water relative permeability,
K_{rwr} = base or top water relative permeability, used to scale the maximum water permeability,
L_α = empirical L parameter for the α phase,
T_α = empirical T parameter for the α phase,

S_{ogw} = residual gas saturation under water displacement,
S_w = water saturation,
S_{wirr} = irreducible water saturation, and
S_{wn} = normalize water saturation.

For the for the primary imbibition or second cycle, IDC2, with the water phase increasing, the oil phase decreasing and the gas phase constant, the LET capillary pressure functions are:

$$P_{cgw} = (P_{cir} - P_{ct}) G_n + (P_{cgr} - P_{ct}) F_n + P_{ct} \quad (8.48)$$

$$where\ S_{wir} \le S_w \le (1 - S_{gorw})\ and\ P_{cgw}(S_w = S_{wzo}) = 0 \Rightarrow E_{sn}$$

$$G_n = \frac{(1 - S_{wn})^{L_{sn}}}{(1 - S_{wn})^{L_{sn}} + E_{sn} S_{wn}^{T_{sn}}} \qquad F_n = \frac{S_{wn}^{L_{fn}}}{S_{wn}^{L_{fn}} + E_{fn}(1 - S_{wn})^{T_{fn}}} \quad (8.49)$$

$$S_{wn} = \frac{S_w - S_{wirr}}{1 - S_{grw} - S_{wirr}} \quad (8.50)$$

Where:

E_{fn} = forced imbibition empirical E parameter,
E_{sn} = spontaneous imbibition empirical E parameter,
L_{fn} = forced imbibition empirical L parameter,
L_{sn} = spontaneous imbibition empirical L parameter,
P_{cir} = capillary pressure at irreducible water saturation,
P_{ct} = capillary threshold / entry pressure,
T_{fn} = forced imbibition empirical T parameter,
T_{sn} = spontaneous imbibition empirical T parameter,
S_{ogw} = residual gas saturation under water displacement,
S_w = water saturation,
S_{wirr} = irreducible water saturation, and
S_{wn} = normalize water saturation.

Table 8.16 relates the general LET equations presented previously with the parameters on the SGOFLET keyword.

LET Function (DCI1) versus SGWFLET Keyword					
SGWFLET	**LET Function**	**SGWFLET**	**LET Function**	**SGWFLET**	**LET Function**

KRTGAS	K_{rgt}	KRTWAT	K_{rwr}		

LET Function (DCI1) versus SGWFLET Keyword					
SGWFLET	**LET Function**	**SGWFLET**	**LET Function**	**SGWFLET**	**LET Function**

Notes:

1) The current implementation of the LET functions is restricted to a single branch capillary pressure curves as shown in Figure 8.20, and not the multi-branch curve shown in Figure 8.21.

Table 8.16: LET Functions (DCI1) versus SGWFLET Keyword

Note

The SGWFLET keyword has not been implemented, as of this current release.

8.2.7 SATURATION TABLE ALLOCATION

Saturation tables are allocated to individual cells using the SATNUM keyword in the REGIONS section for when the hysteresis model option has not been activated on the SATOPTS keyword in the RUNSPEC section. If the hysteresis model option has been activated then the SATNUM keyword allocates the "drainage" saturation tables instead.

If the Directional Dependent Saturation Function option has been activated by the DIRECT parameter on the SATOPTS keyword in the RUNSPEC section, then the KRNUM series of keywords in the REGIONS section may be used to allocate the saturation tables for each grid block face. Here the KRNUMX, KRNUMY and KRNUMZ keywords are used instead of KRNUM. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is KRNUMX, KRNUMX-, KRNUMY, KRNUMY-, KRNUMZ and KRNUMZ-, instead of the KRNUM keyword. Again, if the hysteresis model option has been activated then the KRNUM series of keywords allocate the "drainage" saturation tables instead.

Consequently, if the hysteresis model option has been activated, then the equivalent imbibition keyword, IMBNUM, is used to allocate the imbibition tables. In addition, imbibition saturation table assignment may be directional dependent, in which case the directional dependent versions of the aforementioned IMBNUM array should be used, that is IMBNUMX, IMBNUMY and IMBNUMZ instead of IMBNUM. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is IMBNUMX, IMBNUMX-, IMBNUMY, IMBNUMY-, IMBNUMZ and IMBNUMZ-, instead of the IMBNUM keyword.

The above discussion is based on the assumption that the model is constructed using a Cartesian grid; however, if the model is based on a radial grid then the equivalent radial saturation table allocation keywords should be used. Thus, the equivalent directional KRNUM keywords would be KRNUMR, KRNUMR-, KRNUMT, KRNUMT-, KRNUMZ and KRNUMZ-. Note that the KRNUMZ and KRNUMZ- keywords are used for both Cartesian and radial grids.

For the IMBNUM imbibition keyword for a radial grid, one would use IMBNUMR, IMBNUMR-, IMBNUMT, IMBNUMT-, IMBNUMZ and IMBNUMZ-, and again the IMBNUMZ and IMBNUMZ- keywords are used for both Cartesian and radial grids.

8.3 KEYWORD DEFINITIONS

8.3.1 ADD – ADD A CONSTANT TO A SPECIFIED ARRAY

The ADD keyword adds a constant to a specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the ADD keyword is being applied.

See *ADD – Add a Constant to a Specified Array* in the GRID section for a full description.

8.3.2 ADDREG – ADD A CONSTANT TO AN ARRAY BASED ON A REGION NUMBER

The ADDREG keyword adds a constant to a specified array or part of an array based on cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the ADDREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the ADDREG keyword is being used.

See *ADDREG – Add a Constant to an Array based on a Region Number* in the GRID section for a full description.

8.3.3 ADSALNOD – SALT CONCENTRATION BASED ON SATNUM ARRAY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ADSALNOD defines the salt concentration value based on a cells SATNUM number. The ADSALNOD property is used in the calculation of a polymer viscosity when the polymer and the salt options has been activated by the POLYMER and BRINE keywords in the RUNSPEC section. In the RUNSPEC section the number of SATNUM functions is declared by the NTSFUN variable on the TABDIMS keyword and allocated to individual cells by the SATNUM property array in the REGIONS section. NSSFUN on the TABDIMS keyword in the RUNSPEC section defines the maximum number of rows (or saturation values) in the relative permeability saturation tables and also sets the maximum number of entries for each ADSALNOD data set. The number of values for each data set must correspond to the number of polymer solution adsorption entries on the PLYADSS keyword. For example, if there are three sets of relative permeability tables and four values on the PLYADSS keyword, then three ADSALNOD data sets with four values of salt concentrations need to be entered.

The salt concentrations within each data set should be positive and monotonically increasing and each ADSALNOD data set is delimited by "/" including the last data set.

No.	Name	Description			Default
1	SALTCON	**Field**	**Metric**	**Laboratory**	
		A real positive columnar vector that sets the salt concentrations for the given relative permeability saturation tables.			
		lb/stb	kg/sm3	gm/scc	None
Notes: 1) Each data set must be terminated by a "/" including the last data set.					

Table 8.17:ADSALNOD Keyword Description

An alternative manner of entering the salt concentrations is by utilizing the PVTNUM region array by using the SALTNODE keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

Given three sets of relative permeability tables and four values on the PLYADSS keyword, then the data salt concentration should be entered as follows:

```
--
--    SETS SALT CONCENTRATION FOR POLYMER SOLUTION ADSORPTION
--    VIA SATNUM ARRAY ALLOCATION
--
--    SALT
--
ADSALNOD
      1.0
      5.0
      10.5
      25.0      / SATNUM TABLE NO. 01
      1.0
      3.0
      7.5
      15.0      / SATNUM TABLE NO. 02
      1.0
      7.5
      20.5
      35.0      / SATNUM TABLE NO. 03
```

See also the SALTNODE keyword.

8.3.4 ADSORP – DEFINE GENERALIZED LANGMUIR ADSORPTION FUNCTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ADSORP keyword defines the parameters for the generalized Langmuir Adsorption[178] function for when the polymer, surfact, alkaline, foam and tracers phases have been activated in the RUNSPEC section by the POLYMER, SURFACT, ALKALINE, FOAM and TRACER keywords.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[178] *Langmuir, Irving (June 1918). "The Adsorption of Gases on Plane Surface of Glass, Mica and Platinum". The Research Laboratory of the General Electric Company. 40 (9): 1361–1402. doi:10.1021/ja02242a004*

8.3.5 ALKADS – DEFINE ALKALINE ADSORPTION FUNCTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ALKADS defines the alkaline adsorption functions for when the alkaline model has been activated via the ALKALINE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.6 ALKROCK – DEFINE ROCK ALKALINE PROPERTIES

Description

The ALKROCK keyword defines the rock alkaline properties for when the alkaline model has been activated via the ALKALINE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.7 ALPOLADS – POLYMER ADSORPTION VERSUS ALKALINE CONCENTRATION MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ALPOLDS defines the polymer adsorption versus alkaline concentration multipliers for when the alkaline model has been activated via the ALKALINE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.8 ALSURFAD – SURFACTANT ADSORPTION VERSUS ALKALINE CONCENTRATION MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ALSURAD defines the surfactant adsorption versus alkaline concentration multipliers for when the alkaline model has been activated via the ALKALINE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.9 ALSURFST – WATER-OIL SURFACE TENSION VERSUS ALKALINE CONCENTRATION MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ALSURFST keyword defines the water-oil surface tension versus alkaline concentration multipliers for when the alkaline model has been activated via the ALKALINE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.10 APIGROUP – DEFINE API TRACKING NUMBER OF GROUPED OIL PVT TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

The APIGROUP keyword defines the maximum number of groups of oil PVT tables when the API tracking option has been activated via the API keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.11 AQUCT – DEFINE CARTER-TRACY ANALYTICAL AQUIFERS

The AQUCT keyword defines a Carter Tracy aquifer, the properties of the aquifer, including the Carter-Tracy aquifer influence function associated with the aquifer, defined by the AQUTAB keyword in the PROPS section.

See *AQUCT – Define Carter-Tracy Analytical Aquifers* in the GRID section for a full description

8.3.12 AQUTAB – DEFINE CARTER-TRACY AQUIFER INFLUENCE FUNCTIONS

Description

The AQUTAB keyword defines additional Carter-Tracy[179] aquifer functions to be used in the model. Carter-Tracy representation of the aquifer influx is via a qw term in the non-linear aquifer influence function Q(t). It allows the water influx from the aquifer to be represented in the simulator by assuming that there is a constant water influx rate over finite time periods. It is derived from the superposition methods of van Everdingen and Hurst[180], whose superposition methods are not suitable for implementation in reservoir simulation software, although they are very useful in interpreting aquifer response. The storage requirements and calculation complexity of handling the resulting superposition formulae can be largely eliminated by use of the Carter-Tracy approximate water influx method.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TD	Dimensionless Time			
		dimensionless	dimensionless	dimensionless	None
2	PD	Dimensionless Pressure			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NIFTBL tables as declared on the AQUDIMS keyword in the RUNSPEC section.
2) Each table must contain at least two complete rows with a maximum of NRIFTB rows as declared on the AQUDIMS keyword in the RUNSPEC section. Note that NRIFTB must not be less than 36 in order to accommodate the default infinite acting Carter-Tracy aquifer influence function.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.18:AQUTAB Keyword Description

Note

OPM Flow includes the infinite acting Carter-Tracy aquifer influence table as a default for table number one; thus data entered on this keyword starts from table number two.

Table 8.19 to Table 8.22 outline the standard finite tables derived by van Everdingen and Hurst that are used for the Carter-Tracy analytical aquifers and are taken from Bradely[181] table 38-6 on page 38-12. In the tables rD is defined as the ratio of the aquifer external radius divided by hydrocarbon radius, that is: $r_D = \frac{r_e}{r_o}$.

8.3.13 BDENSITY – DEFINE THE SURFACE BRINE DENSITY FOR THE FLUID

Description

BDENSITY defines the brine surface density for when the brine phase has been activated in the model by the BRINE keyword in the RUNSPEC section. The number of BDENSITY vector data sets is defined by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section. Each record consists of a maximum of NPPVT values, as declared on the TABDIMS keyword in the RUNSPEC section, with each value representing a brine surface density.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

The keyword is used in conjunction with the PVTWSALT keyword in the PROPS section, with each brine density value matching with the salt concentration values in column 1 of each table in the PVTWSALT keyword. Note that the BDENSITY keyword is optional, and if absent from the input file, then the brine surface densities will be set to the water density values declared via the DENSITY keyword in the PROPS section. In this case there is no variation in brine surface density with respect to salt concentration.

No.	Name	Description			Default
1	WATDEN	**Field**	**Metric**	**Laboratory**	
		WATDEN is a real monotonically increasing positive row vector that defines the brine density at surface conditions for the given salt concentrations on the corresponding PVTWSALT keyword in the PROPS section. There should be one row element for each salt concentration columnar element (SALTCON) on the PVTWSALT keyword.			
		lb/ft^3	kg/m	gm/cc	None
Notes: 1) Each row vector data set must be terminated by a "/" including the last data set.					

Table 8.24: BDENSITY Keyword Description

Note

In OPM Flow the tracer equations are solved decoupled from the reservoir equations at the end of a time step. For each tracer an implicit system is solved, however, the tracer equations are linear, resulting in converge in two iterations. However, the Brine phase is solved fully implicitly and is fully coupled with the other flow equations.

This is different to the commercial simulator, where the tracer equations are solved explicitly after the flow equations have converged at the end of a time step. This can lead to numerical instabilities if there are large variations in brine densities.

Example

The following shows the BDENSITY and PVTWSALT keywords for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set equal to two and NPPVT is set to greater than four on the TABDIMS keyword.

8.3.14 BGGI - DEFINE GI GAS FORMATION VOLUME FACTOR PRESSURE TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The BGGI keyword defines Gi gas formation volume factor as a function of Gi and pressure for when the Gi option has been invoked via the GIMODEL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

The accuracy of gas condensate and volatile oil modeling using a black-oil reservoir simulator is now firmly accepted in the industry; both depletion and gas cycling above the saturation point can be modeled and yield an acceptable match compared with compositional simulators. The main deficiency with the existing black-oil formulation is the treatment of gas injection below the saturation point, where the compositional effect of the stripping of liquid components is inversely proportional to their molecular weights, is not considered. This is because the black-oil model assumes that the saturated hydrocarbon fluid properties are only functions of pressure. Thus, when dry gas is injected into a condensate reservoir below the saturation pressure the injected gas continues to re-vaporize liquid at a rate governed only by the cell pressures. Compositional modeling indicate that this not the case.

The GI option attempts to overcome the limitation of the standard black-oil approach by extending the black-oil model using the method of Cook et al.[183] to take into account the fluid property changes occurring during gas injection. This is done by extending the fluid property treatment so that the saturated fluid properties depend on pressure (as per the standard black-oil formulation) and also on an additional parameter which characterizes the compositional changes in the reservoir liquid and vapor phases at constant pressure.

See also the PVTG and GINODE keywords in the PROPS section.

[183] *Cook, R. E., Jacoby, R. H., and Ramesh, A. B. "A Beta-type Reservoir Simulator for Approximating Compositional Effects During Gas Injection" paper SPE 4272, Society of Petroleum Engineers Journal (1974) 14, No. 5, 471-481.*

8.3.15 BOGI - DEFINE GI OIL FORMATION VOLUME FACTOR PRESSURE TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The BOGI keyword defines Gi oil formation volume factor as a function of Gi and pressure for when the Gi option has been invoked via the GIMODEL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

The accuracy of gas condensate and volatile oil modeling using a black-oil reservoir simulator is now firmly accepted in the industry; both depletion and gas cycling above the saturation point can be modeled and yield an acceptable match compared with compositional simulators. The main deficiency with the existing black-oil formulation is the treatment of gas injection below the saturation point, where the compositional effect of the stripping of liquid components is inversely proportional to their molecular weights, is not considered. This is because the black-oil model assumes that the saturated hydrocarbon fluid properties are only functions of pressure. Thus, when dry gas is injected into a condensate reservoir below the saturation pressure the injected gas continues to re-vaporize liquid at a rate governed only by the cell pressures. Compositional modeling indicate that this not the case.

The GI option attempts to overcome the limitation of the standard black-oil approach by extending the black-oil model using the method of Cook et al.[184] to take into account the fluid property changes occurring during gas injection. This is done by extending the fluid property treatment so that the saturated fluid properties depend on pressure (as per the standard black-oil formulation) and also on an additional parameter which characterizes the compositional changes in the reservoir liquid and vapor phases at constant pressure.

See also the PVTG and GINODE keywords in the PROPS section.

[184] *Cook, R. E., Jacoby, R. H., and Ramesh, A. B. "A Beta-type Reservoir Simulator for Approximating Compositional Effects During Gas Injection" paper SPE 4272, Society of Petroleum Engineers Journal (1974) 14, No. 5, 471-481.*

8.3.16 BOX - DEFINE A RANGE OF GRID BLOCKS TO ENTER PROPERTY DATA

BOX defines a range of grid blocks for which subsequent data is assigned for all the cells in the defined BOX. Note that the BOX grid is reset by the keyword ENDBOX by resetting the current defined BOX to be the whole grid. The keyword can be used for any array and for all grid types.

See *BOX - Define a Range of Grid Blocks to Enter Property Data* in the GRID section for a full description.

8.3.17 CNAMES – DEFINE COMPOSITIONAL COMPONENT NAMES

Description

The CNAMES keyword defines the names of the compositional components in the model, as such it should have the same number of entries as that declared via the COMPS keyword in the RUNSPEC section, and the NCOMPS keyword in the PROPS section. The keyword should only be used if the CO2STORE keyword and either the GASWAT or the GAS and WATER keywords in the RUNSPEC section, have also be activated for the gas-water two component model.

Note

This is an OPM Flow keyword used with OPM Flow's CO2STORE and GASWAT keywords in the RUNSPEC section, and should not be confused with the more general version of the CNAMES keyword used in the commercial compositional simulator.

Secondly, although OPM Flow parses the keyword, the simulator currently ignores the data for this keyword.

No.	Name	Description	Default
1	CNAMES	A series of NCOMPS character strings, enclosed in quotes, that define the names of the of the compositional components active in the model. Each character string can be up to eight characters in length. Note that the number of component names should be the same as that enter via the NCOMPS keyword in the PROPS section, and the COMPS keyword in the RUNSPEC section. Secondly, only the default value of two components are currently supported by OPM Flow.	None

Notes:

1) The keyword is terminated by a "/".

Table 8.25: CNAMES Keyword Description

Example

The following example defines how to confirm a two component formulation, together with defining the names of the composition components, to be used with the CO2STORE and GASWAT options.

```
--
--       CONFIRM NUMBER OF COMPOSITIONAL COMPONENTS (OPM FLOW KEYWORD)
--
NCOMPS
        2                                                                 /
--
--       DEFINE COMPOSITIONAL COMPONENTS NAMES (OPM FLOW KEYWORD)
--
CNAMES
        'CO2'
        'H2O'                                                             /
```

8.3.18 COALADS – DEFINE GAS AND SOLVENT RELATIVE ADSORPTION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The COALADS keyword defines the gas and solvent relative adsorption tables for when the coal phase has been activated via the COAL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.19 COALPP – DEFINE GAS AND SOLVENT PARTIAL PRESSURE ADSORPTION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The COALPP keyword defines the gas and solvent partial pressure adsorption tables for when the coal phase has been activated via the COAL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.20 COLUMNS – DEFINE INPUT FILE COLUMN MARGINS

The COLUMNS keyword defines the input file column margins; characters outside the margins are ignored by the input parser.

See *COLUMNS – Define Input File Column Margins* in the GLOBAL section for a full description.

8.3.21 COPY – COPY ARRAY DATA TO ANOTHER ARRAY

The COPY keyword copies an array (or part of an array) to another array or part of an array. The arrays can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the COPY keyword is being used.

See *COPY – Copy Array Data to Another Array* in the GRID section for a full description.

8.3.22 COPYBOX – COPY ARRAY DATA DEFINED BY A BOX

The COPYBOX keyword copies an array (or part of an array) to part of the same array. The array can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the COPYBOX keyword is being used.

See *COPYBOX – Copy Array Data Defined by a Box* in the GRID section for a full description.

8.3.23 COPYREG – COPY AN ARRAY TO ANOTHER ARRAY BASED ON A REGION NUMBER

The COPYREG keyword copies a specified array or part of an array based on cells with a specific region number to another array. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the COPYREG keyword is read by the simulator. The property arrays can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the COPYREG keyword is being used.

See *COPYREG – Copy an Array to Another Array based on a Region Number* in the GRID section for a full description.

8.3.24 DEBUG – DEFINE THE DEBUG DATA TO BE PRINTED TO FILE

This keyword defines the debug data to be written to the debug file (*.DBG). This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

See *DEBUG – Define the Debug Data to be Printed to File* in the GLOBAL section for a full description.

8.3.25 DENSITY – DEFINE THE SURFACE OIL, WATER GAS DENSITIES FOR THE FLUIDS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

DENSITY defines the oil, water and gas surface densities for the fluids for various regions in the model. The number of DENSITY vector data sets is defined by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section and the allocation of the DENSITY data sets to different grid blocks in the model is done via the PVTNUM keyword in the REGIONS section. One data set consists of one record or line which is terminated by a "/". The surface density or gravity must be entered using either the DENSITY or GRAVITY keywords irrespective of which phases are active in the model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	OILDEN	OILDEN is a real number defining the density of the oil phase at surface conditions.			
		lb/ft^3 37.457	kg/m^3 600	gm/cc 0.6	Defined
2	WATDEN	WATDEN is a real number defining the density of the water phase at surface conditions.			
		lb/ft^3 62.366	kg/m^3 999.014	gm/cc 0.999014	Defined
3	GASDEN	GASDEN is a real number defining the density of the gas phase at surface conditions.			
		lb/ft^3 0.062428	kg/m^3 1.000	gm/cc 0.001	Defined

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.26: DENSITY Keyword Description

Note that provided the first table has been entered, subsequent tables may be defaulted, in this case the prior table is copied to the current table. See the third example for an illustration on how to use this feature.

According to the SPE SI standard[185], ***Relative Density*** (γ) replaces ***Specific Gravity*** as the term used to define the ratio of the density of a known material to the density of reference material, at standard conditions of pressure and temperature. Standard conditions vary throughout the world, but for oil field units one normally uses14.7 psia and 60 °F, whereas for SI units some areas use 101.325 kPa and 15 °C.

See also the GRAVITY keyword in the PROPS section, that can be used to enter the relative density values instead of the density numbers.

[185] *The SI Metric System of Units and SPE Metric Standard, Adopted for Use as a Voluntary Standard by the SPE Board of Directors, June 1983, Society of Petroleum Engineers.*

Examples

The following shows the DENSITY keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to one.

```
--
--        OIL      WAT        GAS
--        DENSITY  DENSITY    DENSITY
--        -------  -------    -------
DENSITY
          39.0     62.37      0.04520                        / PVT DATA REGION 1
```

The next example shows the DENSITY keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to three.

```
--
--        OIL      WAT        GAS
--        DENSITY  DENSITY    DENSITY
--        -------  -------    -------
DENSITY
          38.0     62.30      0.04500                        / PVT DATA REGION 1
          39.0     62.37      0.04520                        / PVT DATA REGION 2
          40.0     62.40      0.04800                        / PVT DATA REGION 3
```

The third, and final, example shows the DENSITY keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to four. Here table two defaults to table one, and table four defaults to table three.

```
--
--        OIL      WAT        GAS
--        DENSITY  DENSITY    DENSITY
--        -------  -------    -------
DENSITY
          38.0     62.30      0.04500                        / PVT DATA REGION 1
                                                             / PVT DATA REGION 2
          39.0     62.37      0.04520                        / PVT DATA REGION 3
                                                             / PVT DATA REGION 3
```

Again, note that there is no terminating "/" for this keyword.

8.3.26 DEPTHTAB – RIVER TIME AND DEPTH TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, DEPTHTAB, defines the river time and depth tables, for when the River option has been activated via the RIVRDIMS keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.27 DIAGDISP – ACTIVATE ALTERNATE FORM OF TRACER DISPERSION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, DIAGDISP, activates the alternate form of tracer dispersion matrix for when the Tracer facility has been activated by the TRACERS keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.28 DIFFC – DEFINE PVT REGION MOLECULAR DIFFUSION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFFC keyword defines the molecular weight of the fluids and diffusion coefficients between phases for each PVT region, for when the Molecular Diffusion option has been activated by the DIFFUSE keyword in the RUNSPEC section. This keyword is optional as OPM Flow will automatically calculate the coefficients, as described by Sandve et al.[186], if the DIFFC keyword is absent from the input deck. The keyword thus allows one to overwrite the automatically calculated values.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	OILMW	OILMW is a real positive number that specifies the molecular weight of the oil in the given PVT region.			None
		lb/lb-M	kg/kg-M	gm/gm-M	
2	GASMW	GASMW is a real positive number that defines the molecular weight of the gas in the given PVT region.			None
		lb/lb-M	kg/kg-M	gm/gm-M	
3	GASGASDF	A real positive number that defines the gas in gas diffusion coefficient in the given PVT region.			None
		ft^2/day	m^2/day	cm^2/hour	
4	OILGASDF	A real positive number that declares the oil in gas diffusion coefficient in the given PVT region.			None
		ft^2/day	m^2/day	cm^2/hour	
5	GASOILDF	A real positive number that specifies the gas in oil diffusion coefficient in the given PVT region.			None
		ft^2/day	m^2/day	cm^2/hour	
6	OILOILDF	A real positive number that defines the oil in oil diffusion coefficient in the given PVT region.			None
		ft^2/day	m^2/day	cm^2/hour	
7	GASOILCD	A real positive number that defines the gas in oil cross phase diffusion coefficient in the given PVT region. This parameter is ignored by OPM Flow and should be defaulted or set equal to zero.			0.0
		ft^2/day	m^2/day	cm^2/hour	

[186] *Tor Harald Sandve1, Sarah E. Gasda, Atgeirr Rasmussen, and Alf Birger Rustad. Convective dissolution in field scale CO_2 storage simulation using the OPM Flow simulator. Submitted to TCCS 11 – Trondheim Conference on CO_2 Capture, Transport and Storage Trondheim, Norway – June 21-23, 2021.*

No.	Name	Description			Default
		Field	Metric	Laboratory	
8	OILOILCD	A real positive number that defines the oil in oil cross phase diffusion coefficient in the given PVT region. This parameter is ignored by OPM Flow and should be defaulted or set equal to zero.			0.0
		ft^2/day	m^2/day	cm^2/hour	

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each record is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.27: DIFFC Keyword Description

Note

The option has been tested in combination with the CO2STORE keyword, but not for the general case at this point.

See also the DIFFUSE keyword in the RUNSPEC section to activate the Molecular Diffusion option.

Example

The example below is based on field units, with NTPVT equal to three on the TABDIMS keyword.

```
--
--       PVT REGION MOLECULAR DIFFUSION TABLES
--
DIFFC
--       OIL     GAS    GAS IN   OIL IN   GAS IN   OIL IN   GAS IN   OIL IN
--       MW      MW     GAS DF   GAS DF   OIL DF   OIL DF   OIL CD   OIL CD
--       ------  -----  -------  -------  -------  -------  -------  ------
         103.20  1.120  1.35E-6  1.05E-7  4.50E-7  1.05E-8                /TAB-1
         102.00  1.130  1.25E-6  1.25E-7  4.80E-7  1.05E-8                /TAB-2
         100.00  1.250  1.22E-6                                          /TAB-3
```

Here the third PVT region has no values for the various oil related diffusion coefficients.

8.3.29 DIFFCGAS – DEFINE PVT REGION GAS COMPONENT DIFFUSION COEFFICIENTS

Description

The DIFFCGAS keyword defines the gas diffusion coefficients for each compositional component in the model and for each PVT region, for when the Molecular Diffusion option has been activated by the DIFFUSE keyword in the RUNSPEC section. This keyword is optional as OPM Flow will automatically calculate the coefficients, as described by Sandve et al.[187], if the DIFFCGAS keyword is absent from the input deck. The keyword thus allows one to overwrite the automatically calculated values.

The keyword should only be used if the CO2STORE keyword and either the GASWAT or the GAS and WATER keywords in the RUNSPEC section, have also be activated for the gas-water two component model.

Note

This is an OPM Flow keyword used with OPM Flow's CO2STORE and GASWAT keywords in the RUNSPEC section, and should not be confused with the more general version of the DIFFCGAS keyword used in the commercial compositional simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	CO2DIFF	A real positive number that declares the CO2 in gas diffusion coefficient in the given PVT region.			None
		ft^2/day	m^2/day	cm^2/hour	
2	WATDIFF	A real positive number that specifies the water in gas diffusion coefficient in the given PVT region.			None
		ft^2/day	m^2/day	cm^2/hour	

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each record is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.28: DIFFCGAS Keyword Description

Note

The option has been tested in combination with the CO2STORE keyword, but not for the general case at this point.

See also the DIFFUSE keyword in the RUNSPEC section to activate the Molecular Diffusion option and the DIFFCWAT keyword in the PROPS section that define the water diffusion coefficients for each compositional component in the model and for each PVT region. Finally, for gas-oil systems the DIFFC keyword in the PROPS section should be used.

[187] *Tor Harald Sandve1, Sarah E. Gasda, Atgeirr Rasmussen, and Alf Birger Rustad. Convective dissolution in field scale CO_2 storage simulation using the OPM Flow simulator. Submitted to TCCS 11 – Trondheim Conference on CO_2 Capture, Transport and Storage Trondheim, Norway – June 21-23, 2021.*

Normally diffusion coefficients are measured in laboratory units, that is cm^2/s, for easy of use, Table 8.29 outlines the conversion factors for converting the laboratory measured diffusion coefficients to those used by the simulator.

Diffusivity Conversion Factors		
Laboratory Measured Units	**Conversion Factor**	**Simulator Units**
1 cm^2/s	92.9979 ft^2/day	Field
	8.64 m^2/day	Metric
	3600 cm2/hour	Laboratory

Table 8.29: Diffusivity Conversion Factors

Example

The example below is based on field units, with NTPVT equal to three on the TABDIMS keyword.

```
--
--       PVT REGION GAS COMPONENT DIFFUSION COEFFICIENTS (OPM FLOW KEYWORD)
--
DIFFCGAS
--       CO2 IN   WAT IN
--       GAS DF   GAS DF
--       -------  -------
         0.160    0.150               / PVT REGION NO. 01
         0.165    0.155               / PVT REGION NO. 02
                                      / PVT REGION NO. 03
```

Here the third PVT region has no values for the two component diffusion coefficients, and therefore the simulator will use correlations to define the diffusivity coefficients for this PVT region.

8.3.30 DIFFCOAL – DEFINE COAL BED METHANE GAS DIFFUSION DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DIFF keyword defines the coal bed methane diffusion data for when the Coal Bed Methane option has been activated via the COAL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.31 DIFFCWAT – DEFINE PVT REGION WATER COMPONENT DIFFUSION COEFFICIENTS

Description

The DIFFCWAT keyword defines the water diffusion coefficients for each compositional component in the model and for each PVT region, for when the Molecular Diffusion option has been activated by the DIFFUSE keyword in the RUNSPEC section. This keyword is optional as OPM Flow will automatically calculate the coefficients, as described by Sandve et al.[188], if the DIFFCWAT keyword is absent from the input deck. The keyword thus allows one to overwrite the automatically calculated values.

The keyword should only be used if the CO2STORE keyword and either the GASWAT or the GAS and WATER keywords in the RUNSPEC section, have also be activated for the gas-water two component model.

Note

This is an OPM Flow keyword used with OPM Flow's CO2STORE and GASWAT keywords in the RUNSPEC section, and should not be confused with the more general version of the DIFFCWAT keyword used in the commercial compositional simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	CO2DIFF	A real positive number that declares the CO2 in water diffusion coefficient in the given PVT region.			None
		ft^2/day	m^2/day	cm^2/hour	
2	WATDIFF	A real positive number that specifies the water in water diffusion coefficient in the given PVT region.			None
		ft^2/day	m^2/day	cm^2/hour	

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each record is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.30: DIFFCWAT Keyword Description

Note

The option has been tested in combination with the CO2STORE keyword, but not for the general case at this point.

See also the DIFFUSE keyword in the RUNSPEC section to activate the Molecular Diffusion option and the DIFFCGAS keyword in the PROPS section that define the gas diffusion coefficients for each compositional component in the model and for each PVT region. Finally, for gas-oil systems the DIFFC keyword in the PROPS section should be used.

[188] *Tor Harald Sandve1, Sarah E. Gasda, Atgeirr Rasmussen, and Alf Birger Rustad. Convective dissolution in field scale CO_2 storage simulation using the OPM Flow simulator. Submitted to TCCS 11 – Trondheim Conference on CO_2 Capture, Transport and Storage Trondheim, Norway – June 21-23, 2021.*

Normally diffusion coefficients are measured in laboratory units, that is cm^2/s, for easy of use Table 8.31 outlines the conversion factors for converting the laboratory measured diffusion coefficients to those used by the simulator.

Diffusivity Conversion Factors		
Laboratory Measured Units	**Conversion Factor**	**Simulator Units**
1 cm^2/s	92.9979 ft^2/day	Field
	8.64 m^2/day	Metric
	3600 cm2/hour	Laboratory

Table 8.31: Diffusivity Conversion Factors

Example

The example below is based on field units, with NTPVT equal to three on the TABDIMS keyword.

```
--
--       PVT REGION WATER COMPONENT DIFFUSION COEFFICIENTS (OPM FLOW KEYWORD)
--
DIFFCWAT
--       CO2 IN   WAT IN
--       WAT DF   WAT DF
--       -------  -------
         0.160    0.150               / PVT REGION NO. 01
         0.165    0.155               / PVT REGION NO. 02
                                      / PVT REGION NO. 03
```

Here the third PVT region has no values for the two component diffusion coefficients, and therefore the simulator will use correlations to define the diffusivity coefficients for this PVT region.

8.3.32 DIFFDP – ACTIVATE DUAL POROSITY MOLECULAR DIFFUSION FOR MATRIX-FRACTURE FLOW ONLY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, DIFFDP, activates the dual porosity molecular diffusion for matrix-fracture flow only option for when the Dual Porosity option has be activated by either the DUALPORO or DUALPERM keywords, and the Diffusivity option has been activated by the DIFFUSE keywords; three keywords are in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.33 DIFFMMF – DEFINE DIFFUSIVITY MULTIPLIERS FOR MATRIX-FRACTURES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, DIFFMMF, defines the diffusivity multipliers for matrix-fractures for when the Dual Porosity option has be activated by either the DUALPORO or DUALPERM keywords, or the Coal Bed Methane option is selected by the COAL keyword, and the Diffusivity option has been activated by the DIFFUSE keywords; all four keywords are in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.34 DPKRMOD – MODIFY MATRIX OIL RELATIVE PERMEABILITY DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The DPKRMOD keyword can be used to modify the matrix oil relative permeability data (oil-water, oil-gas) and the scaling of the fracture to matrix relative permeabilities, for dual porosity runs for when a Dual Porosity model has been activated by either the DUALPORO or DUALPERM keywords in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.35 DSPDEINT – ACTIVATE BRINE TRACER DISPERSION INTERPOLATION BY WATER DENSITY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, DSPDEINT, activates the brine tracer dispersion interpolation by water density option for when the Brine phase is activated in the model by the BRINE keyword in the RUNSPEC section and the DISPERSE keyword in the PROPS section is in the input file. They keyword cause the lookup and interpolation of the DISPERSE tracer concentration to water density, that is the tracer concentration data on the DISPERSE keyword has been replaced by the water density data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.36 ECHO – ACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns on echoing of all the input files to the print file; note that this keyword is activated by default and can subsequently be switched off by the NOECHO activation keyword.

See *ECHO – Activate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

8.3.37 EHYSTR – DEFINE HYSTERESIS MODEL AND PARAMETERS

Description

The EHYSTR keyword defines the hysteresis model and associated parameters when the hysteresis option has been activated by the HYSTER variable on the SATOPTS keyword in the RUNSPEC section. Both the Carlson[189] and Killough[190] models are available.

<table>
<tr><th>No.</th><th>Name</th><th>Description</th><th>Default</th></tr>
<tr><td>1</td><td>HYSTRCP</td><td>HYSTRCP is a positive real value that defines the Killough curvature parameter for capillary pressure hysteresis model.

[189] *Carlson, F. M. "Simulation of Relative Permeability Hysteresis to the Non-Wetting Phase," paper SPE 10157, presented at the SPE Annual Technical Conference & Exhibition, San Antonio, Texas, USA (October 5-7, 1981).*

[190] *Killough, J. E. "Reservoir Simulation with History-dependent Saturation Functions," paper SPE 5106, Society of Petroleum Engineers Journal (1976) 16, No. 1, 37-48.*

No.	Name	Description	Default
3	HYSTREL	HYSTREL is a positive real number that defines the Killough's wetting phase relative permeability curvature parameter. This parameter is only applicable if HYSMOD is set to either 4 or 7. This option is ignored by OPM Flow.	1.0
4	HYSTSGR	HYSTSGR is a positive real number that sets a scaling parameter for the trapped non-wetting phase saturation in the Killough model. This option is ignored by OPM Flow.	0.1
5	HYSTOPT	A character string that determines if the hysteresis model should be activated for relative permeability, capillary pressure curves, or both, and should be set to one of the following: 1) BOTH: apply hysteresis modeling to both relative permeability, and capillary pressure curves. 2) PC: apply hysteresis modeling to capillary pressure curves only. 3) KR: apply hysteresis modeling to relative permeability curves only. For all cases HYSTMOD defines the model to be used for relative permeability hysteresis modeling (if applicable). Capillary pressure hysteresis always uses the Killough capillary pressure model. All three options are supported by OPM Flow.	BOTH
6	HYSTSCAN	A character string that determines the shape of Killough capillary pressure scanning curves when secondary reversal curves, that is for a drainage, imbibition, drainage cycle. 1) RETR: Secondary drainage curves re-traverses the same scanning curve. 2) NEW: Secondary drainage curves follows a new scanning curve and further reversals also generate a new scanning curve. This option is ignored by OPM Flow.	RETR
7	HYSTMOB	A character string that determines how to apply the mobility control correction invoked by the MOBILE variable on the EQLOPTS keyword in the RUNSPEC section. HYSTMOB should be set to one of the following: 1) DRAIN: Only the drainage curve end-points are modified. 2) BOTH: Both the drainage and imbibition curve end-points are modified. The Mobility Control option is not supported in OPM Flow so this parameter has no effect.	DRAIN
8	HYSTWET	A character string that sets the wetting phase in three phase systems to either oil or gas and should be set to one of the following: 1) OIL: Oil is set as the wetting phase and the oil-gas relative permeability curves are determined by HYSTMOD for the wetting phase. 2) GAS: Oil is set as the non-wetting phase and the oil-gas relative permeability curves are determined by HYSTMOD for the non-wetting phase. Note for all the above cases the gas relative permeability curves are always treated as as a non-wetting phase. This option is ignored by OPM Flow.	None

No.	Name	Description	Default
9	HYBAKOIL	Baker model one or model two relative permeability oil phase hysteresis option used in the commercial compositional simulator. Not used and should be defaulted with 1*.	NO
10	HYBAKGAS	Baker model one or model two relative permeability gas phase hysteresis option used in the commercial compositional simulator. Not used and should be defaulted with 1*.	NO
11	HYBAKWAT	Baker model one or model two relative permeability water phase hysteresis option used in the commercial compositional simulator. Not used and should be defaulted with 1*.	NO
12	HYTHRESH	Killough's hysteresis threshold saturation value used in the commercial compositional simulator. Not used and should be defaulted with 1*.	0.0
13	HYSWETRP	Killough's hysteresis wetting phase modification used in the commercial black-oil simulator. Not used and should be defaulted with 1*.	0
Notes: 1) The keyword is terminated by a "/".			

Table 8.32: EHYSTR Keyword Description

Example

```
--
--        HYSTERESIS MODEL AND PARAMETERS
--
--        PC-CUR  MODEL   RELPERM TRAPPED OPTION  SHAPE    MOBILIT  WET
--        HYSTRCP HYSTMOD HYSTREL HYSTSGR HYSTOPT HYSTSCAN HYSTMOB  HYSTWET
EHYSTR
          0.1     0       0.1     1*      KR      1*       1*       1*          /
```

The above example defines the hysteresis model and parameters used in the Norne model. Here the default value is used for the Killough curvature parameter for capillary pressure hysteresis mode, the Carlson hysteresis model is used for the non-wetting phase and SATNUM for the wetting phase, 0.1 is used for Killough's wetting phase relative permeability curvature parameter (this parameter is ignored because the Carlson model has been selected), the default values for the trapped non-wetting phase saturation in the Killough mode (again, this parameter is ignored because the Carlson model has been selected, and the hysteresis modeling is only applied to relative permeability curves.

8.3.38 EHYSTRR – DEFINE HYSTERESIS MODEL AND PARAMETERS VIA SATNUM

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The EHYSTRR keyword defines the hysteresis model and associated parameters via the drainage SATNUM allocation region array, for when the hysteresis option has been activated by the HYSTER variable on the SATOPTS keyword in the RUNSPEC section. Only the Killough[191] model is available for this keyword and the keyword is optional.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped. See also the EHYSTR keyword in the RUNSPEC for an alternative keyword to enter the hysteresis model and associated parameters that is supported by OPM Flow

No.	Name	Description	Default
1	HYSTRCP	HYSTRCP is a positive real value that defines the Killough curvature parameter for capillary pressure hysteresis model. The value should range from 0.05 to 0.10.	0.1
2	HYSTREL	HYSTREL is a positive real number that defines the Killough's wetting phase relative permeability curvature parameter. This parameter is ignored if HYSMOD on the EHYSTR keyword is not set to 4.	1.0
3	HYSTSGR	HYSTSGR is a positive real number that sets a scaling parameter for the trapped non-wetting phase saturation in the Killough model.	0.1

Notes:

1) The keyword is followed by NTSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
2) There is no "/" terminator for the keyword.

Table 8.33: EHYSTRR Keyword Description

Example

```
--
--       HYSTERESIS MODEL AND PARAMETERS VIA SATNUM
--
--       PC-CUR  RELPERM TRAPPED
--       HYSTRCP HYSTREL HYSTSGR
EHYSTRR
         0.04    1.0     1*                          / SATNUM REGION 1
         0.06    1.0     1*                          / SATNUM REGION 2
         0.08    1.0     1*                          / SATNUM REGION 3
         0.10    1.0     1*                          / SATNUM REGION 4
         0.10    1.0     1*                          / SATNUM REGION 5
```

The above example defines the hysteresis model and parameters for when NTSFUN equals five on the TABDIMS keyword in the RUNSPEC section, that is for five SATNUM regions.

[191] *Killough, J. E. "Reservoir Simulation with History-dependent Saturation Functions," paper SPE 5106, Society of Petroleum Engineers Journal (1976) 16, No. 1, 37-48.*

8.3.39 END – DEFINE THE END OF THE INPUT FILE

This keyword marks the end of the input file and can occur in any section. Any keywords and data after the END keyword are ignored.

See *END – Define the End of the Input File* in the GLOBAL section for a full description.

8.3.40 ENDBOX – DEFINE THE END OF THE BOX DEFINED GRID

This keyword marks the end of a previously defined BOX sub-grid as defined by a previously entered BOX keyword. The keyword resets the input grid to be the full grid as defined by the NX, NY, and NZ variables on the DIMENS keyword in the RUNSPEC section.

See *ENDBOX – Define the End of the BOX Defined Grid* in the GRID section for a full description.

8.3.41 ENDFIN – END THE DEFINITION OF A LOCAL GRID REFINEMENT

ENDFIN defines the end of a Cartesian or radial local grid refinement ("LGR") definition and a LGR property definition data set.

See *ENDFIN – End the Definition of a Local Grid Refinement* in the GRID section for a full description.

8.3.42 ENDINC – DEFINE THE END OF AN INCLUDE FILE

This keyword marks the end of an include file specified on the INCLUDE keyword. When the ENDINC keyword is encountered in the INCLUDE file, input data is read from the next keyword in the current file. Any keywords and data after the ENDINC keyword in the INCLUDE file are ignored.

See *ENDINC – Define the End of an Include File* in the GLOBAL section for a full description.

8.3.43 ENDSKIP – DEACTIVATE SKIPPING OF KEYWORDS AND INPUT DATA

Turns off skipping of keywords that was activated by the SKIP, SKIP100, or SKIP300 keywords. Note that for each SKIP keyword activated there must be a corresponding ENDSKIP keyword.

See *ENDSKIP – DeActivate Skipping of Keywords and Input Data* in the GLOBAL section for a full description.

8.3.44 ENKRVD – DEFINE RELATIVE PERMEABILITY END-POINTS VERSUS DEPTH FUNCTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the maximum oil, gas, and water relative permeability values versus depth for the three phases and for when the end-point scaling option has been invoked by the ENDSCALE keyword in the RUNSPEC section. This functionality is not supported in OPM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.45 ENPCVD – DEFINE MAXIMUM CAPILLARY PRESSURE VERSUS DEPTH FUNCTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the maximum gas-oil and water-oil capillary pressure values versus depth for when the end-point scaling option has been invoked by the ENDSCALE keyword in the RUNSPEC section

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.46 ENPTVD – DEFINE RELATIVE PERMEABILITY SATURATION END-POINTS VERSUS DEPTH

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the variation of the relative permeability saturation end-points (SWL, SWCR, etc.) for all three phases versus depth for when the end-point scaling option has been invoked by the ENDSCALE keyword in the RUNSPEC section. This functionality is not supported in OPM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.47 ENSPCVD – DEFINE CAPILLARY PRESSURE END-POINTS VERSUS DEPTH

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the variation of the capillary pressure saturation end-points, connate gas (SGL) and connate water (SWL), versus depth for when the end-point scaling option has been invoked by the ENDSCALE keyword in the RUNSPEC section. This functionality is not supported in OPM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.48 EPSDBGS - WRITE END-POINT DEBUG DATA TO THE DEBUG FILE (MULTIPLE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, EPSDBGS, defines the end-point debug data for multiple grid blocks that should be written to the DEBUG file (*.DBG) for when the End-Point Scaling option has been activated by the ENDSCALE keyword in the RONSPEC section.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

8.3.49 EPSDEBUG - WRITE END-POINT DEBUG DATA TO THE DEBUG FILE (INDIVIDUAL)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, EPSDEBUG, defines the end-point debug data for individual grid blocks that should be written to the DEBUG file (*.DBG) for when the End-Point Scaling option has been activated by the ENDSCALE keyword in the RONSPEC section.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

8.3.50 EQUALREG – SETS AN ARRAY TO A CONSTANT BY REGION NUMBER

The EQUALREG keyword sets a specified array to a constant for cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the EQUALREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the EQUALREG keyword is being used.

See *EQUALREG – Sets an Array to a Constant by Region Number* in the GRID section for a full description.

8.3.51 EQUALS – SETS A SPECIFIED ARRAY TO A CONSTANT

The EQUALS keyword sets a specified array or part of an array to a constant. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the EQUALS keyword is being used.

See *EQUALS – Sets a Specified Array to a Constant* in the GRID section for a full description.

8.3.52 ESSNODE – DEFINE SALT CONCENTRATION DATA FOR WATER-OIL SURFACE TENSION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, ESSNODE, defines the salt concentration data that is used in calculating the water-oil surface tension for when the Brine option has been activated by the BRINE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.53 EXTRAPMS – ACTIVATE EXTRAPOLATION WARNING MESSAGES

The EXTRAPMS keyword activates extrapolation warning messages for when OPM Flow extrapolates the PVT or VFP tables. Frequent extrapolation warning messages should be investigated and resolved as this would indicate possible incorrect data and may result in the simulator extrapolating to unrealistic values.

See *EXTRAPMS – Activate Extrapolation Warning Messages* in the GLOBAL section for a full description.

8.3.54 FHERCHBL – DEFINE HERSCHEL-BULKLEY DATA VERSUS POLYMER CONCENTRATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FHERCHBL keyword defines Herschel-Bulkley rheological property data for Non-Newtonian fluids versus polymer concentration, for when the Polymer option has been invoked via the POLYMER keyword in the RUNSPEC section and Non-Newtonian Fluid phase has been declared active by the NNEWTF keyword, also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.55 FILEUNIT – ACTIVATE UNIT CONSISTENCY VERIFICATION

The FILEUNIT keyword defines the units of the of the data set, and is used to verify that the units in the input deck and any associated include files are consistent grid data. The keyword does not provide for the conversion between different sets of units.

See *FILEUNIT – Activate Unit Consistency Checking* in the GRID section for a full description.

8.3.56 FILLEPS – ACTIVATE SATURATION END-POINT EXPORT TO THE INIT FILE

Description

This keyword switches on the export of the saturation end-point data (SWL, SWCR, SOWCR array etc.) to the *.INIT file so that the data can be viewed in post-processing software like OPM ResInsight.

There is no data required for this keyword.

Example

```
--
--       ACTIVATE SATURATION END-POINT EXPORT TO THE INIT FILE
--
FILLEPS
```

The above example switches on the export of the end-point saturation data to the *.INIT file.

8.3.57 FOAMADS - DEFINE FOAM ROCK ADSORPTION TABLES

Description

The FOAMADS keyword defines the foam rock adsorption tables for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	FOAMCON	A columnar vector of real monotonically increasing down the column values that defines the foam concentration in the solution surrounding the rock. The first entry should be zero to define a no foam concentration data set. Units are dependent on the transport phase specified via the FOAMOPT1 variable on the FOAMOPTS keywod in the PROPS section.			
		Gas: lb/Mscf Water: lb/stb	Gas: kg/sm^3 Water: kg/sm^3	Gas: gm/scc Water: gm/scc	None
2	FOAMRATI	A columnar vector of real increasing down the column values that defines the mass of adsorbed foam per unit mass of rock for a given FOAMCON. The first table data set entry should be zero to define a no foam concentration data set.			
		lb/lb	kg/kg	gm/gm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.34: FOAMADS Keyword Description

Example

```
--
--        FOAM ROCK ADSORPTION TABLE
--
FOAMADS
--        FOAM        FOAM
--        FOAMCON     FOAMRATI
--        -------     --------
              0.0      0.00000
              2.0      0.00003
              4.0      0.00005
              6.0      0.00007
              8.0      0.00009
             10.0      0.00011
             12.0      0.00012
             14.0      0.00015                              / TABLE NO. 01
--        FOAM        FOAM
--        FOAMCON     FOAMRATI
--        -------     --------
              0.0      0.00000
              3.0      0.00004
              5.0      0.00006
              7.0      0.00008
              8.0      0.00009
             10.0      0.00011                              / TABLE NO. 02
```

The above example defines two foam rock adsorption tables assuming NTSFUN equals two and NSSFUN is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section.

8.3.58 FOAMDCYO – DEFINE FOAM DECAY VERSUS OIL SATURATION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMDCYO keyword defines the foam decay half-life versus oil saturation for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.59 FOAMDCYW – DEFINE FOAM DECAY VERSUS WATER SATURATION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMDCYW keyword defines the foam decay half-life versus water saturation for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.60 FOAMFCN – DEFINE FOAM GAS MOBILITY REDUCTION VERSUS CAPILLARY NUMBER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMFCN keyword defines the reduction in gas mobility versus capillary number, for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section, and the FOAMOPT2 parameter on the FOAMOPTS keyword in the PROPS section has been set to the character string FUNC.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.61 FOAMFRM – DEFINE FOAM GAS MOBILITY REDUCTION VERSUS REFERENCE MOBILITY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMFRM keyword defines the reduction in gas mobility versus the reference mobility reduction factor, for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section, and the FOAMOPT2 parameter on the FOAMOPTS keyword in the PROPS section has been set to the character string FUNC.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.62 FOAMFSC – DEFINE FOAM GAS MOBILITY VERSUS SURFACTANT CONCENTRATION FUNCTIONS

Description

The FOAMFSC keyword defines the reduction in gas mobility as a function of the foam surfactant concentration within a grid block. The Foam option must be activated by the FOAM keyword in the RUNSPEC section in order to use this keyword. In addition, the FOAMOPT2 parameter on the FOAMOPTS keyword in the PROPS section must be set to the character string FUNC, in order to activate the functional form of the gas mobility reduction calculations.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	FOAMCON	A real positive value that defines the foam surfactant concentration at which foam modeling becomes active in the model and a strong foam is formed. FOAMCON cannot be defaulted and must be specified for the first table. Subsequent tables can be defaulted and will in this case use the previous tables' entries as the default value.			
		lb/stb	kg/sm^3	gm/scc	None
2	FOAMEXP	A real positive value that defines an exponent that determines the gradient in the change of the reduction in gas mobility due to foam (es in equation (8.51). Note if e_s is less than one then the slope of F_s in equation (8.51) will be infinite at C_s equal to zero. In this case, small surfactant concentrations have a significant effect on the mobility, especially if the reference concentration Csr is also small. If this is the case use MINSURF on this keyword to set a minimum surfactant concentration to avoid small-scale numerical errors from affecting the simulation.			
		dimensionless 1.0	dimensionless 1.0	dimensionless 1.0	Defined
3	MINSURF	MINSURF is a real positive value that defines the minimum surfactant concentration for which the reduction in gas mobility will be calculated. The default value of 1 x 10-20 implies that there is no minimum			
		lb/stb 1×10^{-20}	kg/sm^3 1×10^{-20}	gm/scc 1×10^{-20}	Defined
4	MINSWAT	MINSWAT is a real positive value less than 1.0 that sets the minimum water saturation below which foam has no effect. The default value of 1 x 10-6 implies that there is no minimum. Note that this parameter is only used in the commercial simulator's compositional simulator and is therefore not used by OPM Flow or the commercial simulators black-oil simulator.			
		dimensionless 1×10^{-6}	dimensionless 1×10^{-6}	dimensionless 1×10^{-6}	Defined

No.	Name	Description			Default
		Field	Metric	Laboratory	
Notes: 1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section. 2) Each table must contain just one row and one row only. 3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.					

Table 8.35: FOAMFSC Keyword Description

The gas mobility reduction as a function of surfactant concentration is of the form:

$$F_s = \left(\frac{C_s}{C_s^r} \right)^{e_s} \tag{8.51}$$

Where:

Fs = the resulting gas mobility reduction factor as a function of surfactant concentration,
Cs = surfactant concentration,
Crs = reference surfactant concentration, that is Cs < Csr defines a weak foam and
Cs > Csr defines a strong foam (FOAMCON), and
es = exponent that determines the gradient in the change of the reduction in gas mobility due to foam (FAOAMEXP).

The functional form of the reduction in gas mobility factor (Mrf) is:

$$M_{rf} = \frac{1}{1 + \left(M_r \times F_s \times F_w \times F_o \times F_c \right)} \tag{8.52}$$

Where:

Mr = the reference mobility reduction factor, see the FOAMFRM keyword in the PROPS section,
Fs = gas mobility reduction factor as a function of surfactant concentration, see the FOAMFSC keyword in the PROPS section,
Fw = gas mobility reduction factor as a function of water saturation, see the FOAMFSW keyword in the PROPS section,
Fo = gas mobility reduction factor as a function of oil saturation, see the FOAMFSO keyword in the PROPS section, and
Fc = gas mobility reduction factor as a function of capillary number, see the FOAMFCN keyword in the PROPS section.

See also the FOAM keyword in the RUNSPEC section, the FOAMADS, FOAMMOB, FOAMOPTS and FOAMROCK keywords in the PROPS section.

Example

```
--
--       FOAM GAS MOBILITY VERSUS SURFACTANT CONCENTRATION FUNCTIONS
--
FOAMFSC
--       FOAM       FOAM      FOAM      FOAM
--       FOAMCON    FOAMEXP   MINSURF   MINSWAT
--       -------    -------   -------   -------
           0.001      1.010                        / TABLE NO. 01
           0.002      1.000                        / TABLE NO. 02
                                                   / TABLE NO. 03 (DEFAULTED)
           0.001      0.850  1.0E-10               / TABLE NO. 04
           0.002      1.030                        / TABLE NO. 05
           0.002      1.000                        / TABLE NO. 06
```

Here, NTSFUN equals six on the TABDIMS keyword in the RUNSPEC section and therefore six entries are required for the FOAMFSC keyword. Table number three is completed defaulted and will therefore use all the properties from the previous table, that is table number two.

8.3.63 FOAMFSO – DEFINE FOAM GAS MOBILITY REDUCTION VERSUS OIL SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMFSO keyword defines the reduction in gas mobility versus oil saturation, for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section, and the FOAMOPT2 parameter on the FOAMOPTS keyword in the PROPS section has been set to the character string FUNC.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.64 FOAMFST – DEFINE FOAM GAS-WATER SURFACE TENSION VERSUS SURFACTANT CONCENTRATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMFST keyword defines the gas-water surface tension versus the foam surfactant concentration, for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section, and the FOAMOPT2 parameter on the FOAMOPTS keyword in the PROPS section has been set to the character string FUNC.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.65 FOAMFSW – DEFINE FOAM GAS MOBILITY REDUCTION VERSUS WATER SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMFRM keyword defines the reduction in gas mobility versus water saturation, for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section, and the FOAMOPT2 parameter on the FOAMOPTS keyword in the PROPS section has been set to the character string FUNC.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.66 FOAMMOB - DEFINE FOAM GAS MOBILITY VERSUS FOAM CONCENTRATION TABLES

Description

The FOAMMOB keyword defines the reduction in gas mobility as a function of the foam concentration within a grid block. The Foam option must be activated by the FOAM keyword in the RUNSPEC section in order to use this keyword. In addition, this keyword must be supplied if the foam model is activated.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	FOAMCON	A columnar vector of real monotonically increasing down the column values that defines the foam concentration for the corresponding gas mobility reduction factor (FOAMRATI). The first entry should be zero to define a no foam concentration data set. Units are dependent on the transport phase specified via the FOAMOPT1 variable on the FOAMOPTS keyword in the PROPS section. FOAMOPT1 should be set to either GAS or WATER.			
		Gas: lb/Mscf Water: lb/stb	Gas: kg/sm^3 Water: kg/sm^3	Gas: gm/scc Water: gm/scc	None
2	FOAMRATI	A columnar vector of real decreasing down the column values that defines the corresponding gas mobility reduction factor for a given FOAMCON. The first table data set entry should be one to define a no foam concentration data set. Each FOAMCON/FOAMRATI data set should be terminated by a "/"			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.36: FOAMMOB Keyword Description

See also the FOAM keyword in the RUNSPEC section, the FOAMADS, FOAMOPTS and FOAMROCK keywords in the PROPS section.

Example

```
--
--        FOAM GAS MOBILITY VERSUS FOAM CONCENTRATION TABLES
--
FOAMMOB
--        FOAM        FOAM
--        FOAMCON     FOAMRATI
--        -------     --------
            0.000      1.00000
            0.005      0.50000
            0.010      0.20000
            0.015      0.10000
            0.020      0.07500
            0.025      0.07000
            0.030      0.06500
            0.035      0.06500                              / TABLE NO. 01
--        FOAM        FOAM
--        FOAMCON     FOAMRATI
--        -------     --------
            0.000      1.00000
            0.010      0.50000
            0.015      0.25000
            0.020      0.07500
            0.025      0.07000
            0.030      0.07000                              / TABLE NO. 02
```

Given NTPVT equals two and NPPVT is greater and or equal to eight on the TABDIMS keyword in the RUNSPEC section, the example defines the foam gas mobility versus foam concentration tables for two tables.

There is no terminating "/" for this keyword.

8.3.67 FOAMMOBP – DEFINE FOAM MOBILITY REDUCTION VERSUS OIL PRESSURE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMMOBP keyword defines the reduction in foam mobility reduction versus oil pressure, for when the Foam option has been activated by the FOAM keyword in the RUNSPEC.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.68 FOAMMOBS – DEFINE FOAM MOBILITY REDUCTION VERSUS SHEAR

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The FOAMMOBS keyword defines the reduction in foam mobility reduction versus shear, for when the Foam option has been activated by the FOAM keyword in the RUNSPEC.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.69 FOAMOPTS - DEFINE FOAM MODEL OPTIONS

Description

The FOAMOPTS keyword defines the transport phase for the foam (gas, water or solvent) and how gas mobility reduction should be calculated for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section.

No.	Name	Description	Default
1	FOAMOPT1	A defined character string that specifies the transport phase for the foam, and should be set to one of the following: 1) GAS: for the foam to be transport in the gas phase., 2) WATER: for the foam to be transported in the water phase, or 3) SOLVENT: for the foam to be transported in the solvent phase.	GAS
2	FOAMOPT2	A defined character string that specifies the method to be used to calculate the reduction in gas mobility, and should be set to one of the following: 1) TAB: Sets the reduction in gas mobility is to be calculated based on tables using the FOAMMOB keyword as a function of foam concentration, the FOAMMOBS keyword as a function of shear, or as a function of pressure using the FOAMMOBP keyword. All keywords are in the PROPS section. 2) FUNC: Sets the reduction in gas mobility to be calculated based on a function defined via the FOAMFRM, FOAMFSC, FOAMFSW, FOAMFSO, FOAMFCN, or FOAMFST keywords in the PROPS section. Only the default value of TAB is currently supported by OPM Flow.	TAB
Notes: 1) The keyword is terminated by a "/".			

Table 8.37: FOAMOPTS Keyword Description

Example

```
--
--        FOAMOPT1  FOAMOPT2
--        PHASE     MOBILITY
--        --------  --------
FOAMOPTS
          GAS       TAB                                  / FOAM MODEL OPTIONS
```

The above example defines the transport phase is to be gas and the gas mobility reduction is to use a table as defined by the FOAMMOB keyword as a function of foam concentration, the FOAMMOBS keyword as a function of shear, or as a function of pressure using the FOAMMOBP keyword.

8.3.70 FOAMROCK - DEFINE FOAM ROCK PROPERTIES

Description

The FOAMROCK keyword defines the foam rock properties for when the Foam option has been activated by the FOAM keyword in the RUNSPEC section.

The keyword is recognized by the input deck parser and simulator support is available in the experimental "ebos" simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ADINDX	A positive integer of 1 or 2 that defines foam desorption option, as per: 1) then foam desorption may occur by retracing the foam adsorption isotherm when the local foam concentration in the solution decreases. 2) then no foam desorption may occur. Only the default value of 1 is supported by OPM Flow.			
		dimensionless 1	dimensionless 1	dimensionless 1	Defined
2	DENSITY	A real value that defines the rock in situ density, that is at reservoir conditions.			
		lb/rb	kg/rm^3	gm/rcc	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain just one row and one row only.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.38: FOAMROCK Keyword Description

Note

In the commercial simulator if the POLYMER and SURFACT phases have been activated in conjunction with the FOAM phase then the mass density of rock will be set by the PLYROCK, SURFROCK, or the FOAMROCK keywords depending on the order entered in the run deck. This is not the case for OPM Flow.

OPM Flow's FOAM phase is a standalone implementation and cannot be used in conjunction with the either the POLYMER or SURFACT phases.

Example

```
--
--       FOAM-ROCK PROPERTIES
--
FOAMROCK
--       DESORP   INSITU
--       OPTN     DENSITY
--       ------   -------
           1      1800.0                                  / TABLE NO. 01
           2      1980.0                                  / TABLE NO. 02
           1      2005.0                                  / TABLE NO. 03
```

The above example defines three foam-rock tables, based on the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section being equal to three.

There is no terminating "/" for this keyword.

8.3.71 FORMFEED – DEFINED THE PRINT FILE FORM-FEED CHARACTER

The FORMFEED keyword defines the form-feed character, or carriage control character, for the output print (*.PRT) run summary (*.RSM) files. The keyword should be place at the very top of the input file.

See *FORMFEED – Defined the Print File Form-Feed Character* in the GLOBAL section for a dull description.

8.3.72 GASDENT – DEFINE GAS DENSITY TEMPERATURE COEFFICIENTS

Description

GASDENT defines the gas density as a function of temperature coefficients for when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC. Note this is an OPM Flow keyword used with OPM Flow's black-oil thermal model that is not available in the commercial simulator's black-oil thermal formulation.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	TEMP is a real positive value greater than zero that defines the absolute reference temperature used with TEXP1 and TEXP2 to estimate the change in gas density with respect to temperature.			
		°R 527.67	°K 293.15	°K 293.15	Defined
2	TEXP1	TEXP1 is a real positive value greater than zero that defines the gas thermal expansion coefficient of the first order.			
		1/°R 1.67×10^{-4}	1/°K 3.0×10^{-4}	1/°K 3.0×10^{-4}	Defined
3	TEXP2	TEXP2 is a real positive value greater than zero that defines the gas thermal expansion coefficient of the second order.			
		1/°R2 9.26×10^{-7}	1/°K2 3.0×10^{-6}	1/°K2 3.0×10^{-6}	Defined

Notes:

1) The keyword is followed by NTPVT records as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each data set is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.39: GASDENT Keyword Description

The gas density at a given pressure and temperature is calculated from its value at surface conditions and the gas expansion factor (the reciprocal of the gas formation volume factor) as shown in the following equation:

$$\rho_g(p,T) = \rho_g(p_s,T_s)\, b_g(p,T) \tag{8.53}$$

Where the temperature dependence of the gas expansion factor relative to its value at the reference temperature is calculated as shown in the following equation:

$$b_g(p,T)=\frac{b_g(p,T_{ref})}{1+c_1(T-T_{ref})+c_2(T-T_{ref})^2} \tag{8.54}$$

Where:

ρ_g = gas density
b_g = gas expansion factor
p = pressure
T = temperature
c_1, c_2 = thermal expansion coefficients to first and second order
s = subscript indicating surface conditions
ref = subscript indicating reference conditions

Example

The following example shows the GASDENT keyword using the default values, for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to two.

```
--
--       GAS DENSITY TEMPERATURE COEFFICIENTS (OPM FLOW THERMAL KEYWORD)
--
--       GAS         DENSITY   DENSITY
--       TEMP        COEFF1    COEFF2
--       --------    -------   -------
GASDENT
         1*          1*        1*                          / TABLE NO. 01
         1*          1*        1*                          / TABLE NO. 02
```

There is no terminating "/" for this keyword.

8.3.73 GASJT – DEFINE GAS JOULE-THOMSON COEFFICIENT

Description

GASJT activates the gas Joule-Thomson[192] effect in temperature calculations, and defines the gas Joule-Thomson Coefficient ("JTC") at a given reference pressure, for when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC.

Note

This is an OPM Flow keyword used with OPM Flow's black-oil thermal model, that is not available in the commercial simulator's black-oil thermal formulation.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model, and does not include the Joule-Thomson effect in temperature calculations.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A real positive value that defines the reference pressure for the corresponding Joule-Thomson Coefficient, GASJTC.			
		psia	barsa	atma	None
2	GASJTC	GASJTC is a real positive or negative value that defines the gas phase Joule-Thomson Coefficient. If the value is defaulted (1*) or set to 0, then GASJTC is internally calculated using the thermal gas density data on the GASDENT keyword in the PROPS section. If a non-zero value is specified, then the GASJTC is assumed to be constant and equal to that value.			
		oF/psia	°C/barsa	°C/atma	0

Notes:

1) The keyword is followed by NTPVT records as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each data set is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.40: GASJT Keyword Description

The Joule–Thomson effect is when a real gas, as oppose to an ideal gas, expands, resulting in the temperature of the gas dropping. During passage of a gas through a choke, the internal energy is transferred to kinetic energy with a corresponding reduction in temperature as the velocity increases. The effect for natural gas is approximately 7 °F for every 100 psi pressure reduction, or 0.5 oC per barsa[193], is valid for "normal" pressures and temperatures at the surface.

[192] *Natural Gas Engineering (McGraw-Hill chemical engineering series), Donald L. Katz, Robert I Lee, McGraw-Hill Education, 1990 (ISBN 0071007776, 9780071007771).*

[193] *https://petrowiki.spe.org/Glossary:Joule-thompson_effect.*

Thermodynamically, the Joule–Thomson coefficient is defined as the isenthalpic[194] change in temperature in a fluid caused by a unitary pressure drop, as shown in the following equation:

$$\eta = \left(\frac{\partial T}{\partial P}\right) \tag{8.55}$$

One can also express enthalpy changes in terms of pressure, temperature and volume changes:

$$\eta = \frac{RT^2}{Pc_p}\left(\frac{\partial Z}{\partial T}\right)_P \tag{8.56}$$

Where:

η	=	Joule–Thomson coefficient,
C_g	=	specific heat at constant pressure,
P	=	pressure,
R	=	gas constant,
T	=	temperature, and
Z	=	gas compressibility factor.

Example

The following example shows the GASJT keyword for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section, and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set equal to two.

```
--
--       GAS JOULE-THOMSON COEFFICIENT (OPM FLOW EXTENSION KEYWORD)
--
--       REF         GAS
--       PRESS       JTC
--       --------    -------
GASJT
         20.0        1*                  / TABLE NO. 01
         20.0        0.50                / TABLE NO. 02
```

Here the first entry is defaulted, and the simulator will therefore calculate the gas JTC internally using the data on the GASDENT keyword in the PROPS section.

There is no terminating "/" for this keyword.

[194] *An isenthalpic process or isoenthalpic process, is a process that proceeds without any change in enthalpy, H; or specific enthalpy, h.*

8.3.74 GASVISCT - DEFINE GAS VISCOSITY VERSUS TEMPERATURE FUNCTIONS

Description

GASVISCT defines the gas viscosity as a function of temperature for when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC. The reference pressure for this table is given by the VISCREF keyword in the PROPS section. Note this is an OPM Flow keyword used with OPM Flow's black-oil thermal model that is not available in the commercial simulator's black-oil thermal formulation. However, the keyword and similar functionality is available in the commercial compositional simulator.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	A columnar vector of real monotonically increasing down the column values that defines the temperature values.			
		°F	°C	°C	None
2	VIS	A columnar vector of real increasing down the column values that defines the gas viscosity for the corresponding temperature values (TEMP). VIS should be given at the reference pressure defined by the PRESS variable on the VISCREF keyword.			
		cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.41: GASVISCT Keyword Description

Example

The following example shows the GASVISCT keyword for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set equal to one.

```
--
--       GAS VISCOSITY VERSUS TEMPERATURE TABLES (OPM FLOW EXTENSION KEYWORD)
--
--       GAS         GAS
--       TEMP        VISC
--       --------    -------
GASVISCT
           100.0     0.0500
           110.0     0.0550
           120.0     0.0580
           150.0     0.0620
           165.0     0.0625                                  / TABLE NO. 01
```

There is no terminating "/" for this keyword.

8.3.75 GETDATA – LOAD AND ASSIGN DATA ARRAY FROM INIT OR RESTART FILE

The GETDATA keyword loads a data array from a previously generated INIT or RESTART file and assigns the loaded array to either same array in the run or another array name.

See *GETDATA – Load and Assign Data Array from INIT or RESTART Files* in the GRID section for a full description.

8.3.76 GIALL – DEFINE GI VALUES AND PVT PROPERTIES VERSUS PRESSURE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The GIALL keyword defines the GI values and the associated RVGI, RSGI, BGGI and BOGI values as a function of pressure, for when the GI Pseudo Compositional option has been activated in the model via the GIMODEL keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.77 GINODE – DEFINE GI NODE VALUES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The GINODE keyword defines the Gi node values used when the GIMODEL keyword in the RUNSPEC section has been used to activate the GI Pseudo Compositional option for the run. The keyword is used in conjunction with the RSGI, RVGI, BGGI and BOGI keywords in the PROPS section to describe the fluid properties for the GI Pseudo Compositional option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.78 GRAVCONS – RE-DEFINE GRAVITY CONSTANT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The GRAVCONS keyword re-defines the gravity constant used in various calculations from the default value used by the simulator. Normally this keyword should not be used.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	GRAVCONS	GRAVCONS is a positive real number number that defines the gravity constant used in various calculations.			
		ft^2psi/lb 0.00694	m^2bars/kg 0.0000981	cm^2atm/gm 0.000968	Defined
Notes: 1) The keyword is terminated by a "/".					

Table 8.42: GRAVCONS Keyword Description

Example

```
--
--       RE-DEFINE GRAVITY CONSTANT
--
GRAVITY
         0.0000980665                                    /
```

The above example re-defines the gravity constant to be 0.0000980665 ft2psi/lb from the default value of 0.00694 ft2psi/lb.

8.3.79 GRAVITY– DEFINE THE SURFACE OIL, WATER GAS GRAVITIES FOR THE FLUIDS

Description

GRAVITY defines the oil API gravity and water and gas surface specific gravities for the fluids for various regions in the model. The number of GRAVITY vector data sets is defined by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section and the allocation of the GRAVITY data sets to different grid blocks in the model is done via the PVTNUM keyword in the REGION section. One data set consists of one record or line which is terminated by a "/".

This surface density or gravity must be entered using either the DENSITY or GRAVITY keywords irrespective of which phases are active in the model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	OILAPI	OILAPI is a real number defining the API gravity of the oil phase at surface conditions. The American Petroleum Institute ("API") classifies oils based on an API gravity (γ_{API}), or degrees API (°API), the relationship between relative density (γ_o) of oil and API gravity (γ_{API}) is given by: $$\gamma_{API} = \frac{141.5}{\gamma_o} - 131.5$$			
		°API	°API	°API	None
2	WATGRAV	WATGRAV is a real number defining the specific gravity of the water phase relative to pure water at surface conditions.			
		(water =1.0) 0.7773	(water =1.0) 0.7773	(water =1.0) 0.7773	Defined
3	GASGRAV	GASGRAV is a real number defining the specific gravity of the gas phase relative to air at surface conditions.			
		(air =1.0) 1.000	(air =1.0) 1.000	(air =1.0) 1.000	Defined
Notes: 1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section. 2) Each data set is by terminated by a "/" at the end of the line and there is no "/" terminator for the keyword.					

Table 8.43: GRAVITY Keyword Description

According to the SPE SI standard[195], ***Relative Density*** (γ) replaces ***Specific Gravity*** as the term used to define the ratio of the density of a known material to the density of reference material, at standard conditions of pressure and temperature. Standard conditions vary throughout the world, but for oil field units one normally uses14.7 psia and 60 °F, while for SI units some areas use 101.325 kPa and 15 °C.

Note that provided the first table has been entered, subsequent tables may be defaulted, in this case the

[195] *The SI Metric System of Units and SPE Metric Standard, Adopted for Use as a Voluntary Standard by the SPE Board of Directors, June 1983, Society of Petroleum Engineers.*

prior table is copied to the current table. See the third example for an illustration on how to use this feature. See also the DENSITY keyword in the PROPS section.

Examples

The following shows the GRAVITY keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to one.

```
--
--        OIL      WAT        GAS
--        GRAVITY  GRAVITY    GRAVITY
--        -------  -------    -------
GRAVITY
           39.0     1.012      0.650                / GRAVITY PVT DATA REGION 1
```

The next example shows the GRAVITY keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to three.

```
--
--        OIL      WAT        GAS
--        GRAVITY  GRAVITY    GRAVITY
--        -------  -------    -------
GRAVITY
           37.0     1.012      0.650                / GRAVITY PVT DATA REGION 1
           38.0     1.012      0.646                / GRAVITY PVT DATA REGION 2
           39.0     1.012      0.640                / GRAVITY PVT DATA REGION 3
```

The third and final example shows the GRAVITY keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to four. Here table two defaults to table one, and table four defaults to table three.

```
--
--        OIL      WAT        GAS
--        GRAVITY  GRAVITY    GRAVITY
--        -------  -------    -------
GRAVITY
           37.0     1.012      0.650                / GRAVITY PVT DATA REGION 1
                                                    / GRAVITY PVT DATA REGION 2

```

Again, note that there is no terminating "/" for this keyword.

8.3.80 GSF - GAS SATURATION FUNCTION TABLES (GAS-WATER SYSTEMS)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The GSF keyword defines the gas relative permeability and gas-water capillary pressure data versus gas saturation tables for when only gas and water are present in the input deck. This keyword should only be used if the gas and water phases are present in the run, and can therefore also be used with the CO2STORE and H2STORE models. In addition, the keyword must be used in conjunction with the WSF keyword in the PROPS section, that defines the water relative permeability versus water saturation for gas-water systems.

Note

GSF is a compositional keyword in the commercial compositional simulator, and will therefore cause an error in the commercial black-oil simulator.

Currently, both the GSF and WSF keywords can only be used with the CO2STORE and H2STORE models.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGAS	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the gas saturation.			
		dimensionless	dimensionless	dimensionless	None
2	KRG	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the gas relative permeability. Note that the first entry in the column must be zero.			
		dimensionless	dimensionless	dimensionless	None
3	PCWG	A columnar vector of real values that are either equal or increasing down the column that defines the gas-water capillary pressure.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.44: GSF Keyword Description

See also the *WSF - Water Saturation Tables versus Water Saturation (Gas-Water and CO2STORE Systems)* keyword in the PROPS section, that defines the water saturation as a function of water saturation for when only the gas and water phases are present in the model.

              0.55    0.1020      0.0
              0.60    0.1412      0.0
              0.65    0.1870      0.0
              0.70    0.2412      0.0
              0.77    0.3288      0.0
              0.82    0.4000      0.0
              0.85    0.4450      0.0                        / TABLE NO. 02
```

The example defines two GSF tables for when gas and water are present in the input deck. In the tables the gas-water capillary pressure data has been set to zero.

8.3.81 HA – HISTORY MATCH END-POINT GRADIENT ADDITIVE MODIFIER

Description

The HA series of keywords defines the history match end-point gradient parameters used to set the additive cumulative end point data, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. In addition, the End-Point Scaling option must also be activated by the ENDSCALE keyword which is also in the RUNSPEC section. The keyword consists of the first two characters of "HA" followed by the end-point keyword shown in Table 8.45, for example, HASWL.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Type	End-Point Keyword	Oil-Water End-Point Definitions
Saturation	SWL	Connate water saturation, that is the smallest water saturation in a water saturation function table.
	SWCR	Critical water saturation, that is the largest water saturation for which the water relative permeability is zero.
	SOWCR	Critical oil-in-water saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-water system.
Relative Permeability	KRW	Relative permeability of water at the maximum water saturation (normally the maximum water saturation is one).
	KRO	Relative permeability of oil at the maximum oil saturation.
	KRWR	Relative permeability of water at the residual oil saturation or the residual gas saturation in a gas-water run.
	KRORW	Relative permeability of oil at the critical water saturation.
Capillary Pressure	SWLPC	Capillary pressure connate water saturation, that is the smallest water saturation in a water saturation function table.
Type	**End-Point Keyword**	**Gas-Oil End-Point Definitions**
Saturation	SGL	Connate gas saturation, that is the smallest gas saturation in a gas saturation function table.
	SGCR	Critical gas saturation, that is the largest gas saturation for which the gas relative permeability is zero.
	SOGCR	Critical oil-in-gas saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-gas-connate water system.
Relative Permeability	KRG	Relative permeability of gas at the maximum gas saturation.
	KRGR	Relative permeability of gas at the residual oil saturation or the critical water saturation in a gas-water run.
	KRORG	Relative permeability of oil at the critical gas saturation.

Type	End-Point Keyword	Oil-Water End-Point Definitions
Capillary Pressure	SGLPC	Capillary pressure connate gas saturation, that is the smallest gas saturation in a gas saturation function table.

Table 8.45: HA Keyword List

See also the HMPROPS keyword in the PROPS section that allows the use of the ADD, BOX, EQUALS, COPY, MINVALUE, and MAXVALUE keywords to be used with the HA and HM series of keywords.

8.3.82 HDISP – DEFINE TRACER MECHANICAL DISPERSIVITY PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HDISP keyword is combined with three character tracer name, specified by the TRACER keyword in the PROPS section, to define the tracer's mechanical dispersivity parameters.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.83 HM – HISTORY MATCH END-POINT GRADIENT MULTIPLICATIVE MODIFIER

Description

The HM series of keywords defines the history match end-point gradient parameters used to set the multiplicative cumulative end point data, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. In addition, the End-Point Scaling option must also be activated by the ENDSCALE keyword which is also in the RUNSPEC section. The keyword consists of the first two characters of "HM" followed by the end-point keyword shown in Table 8.46, for example, HMSWL.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Type	End-Point Keyword	Oil-Water End-Point Definitions
Saturation	SWL	Connate water saturation, that is the smallest water saturation in a water saturation function table.
	SWCR	Critical water saturation, that is the largest water saturation for which the water relative permeability is zero.
	SOWCR	Critical oil-in-water saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-water system.
Relative Permeability	KRW	Relative permeability of water at the maximum water saturation (normally the maximum water saturation is one).
	KRO	Relative permeability of oil at the maximum oil saturation.
	KRWR	Relative permeability of water at the residual oil saturation or the residual gas saturation in a gas-water run.
	KRORW	Relative permeability of oil at the critical water saturation.
Capillary Pressure	SWLPC	Capillary pressure connate water saturation, that is the smallest water saturation in a water saturation function table.
Type	**End-Point Keyword**	**Gas-Oil End-Point Definitions**
Saturation	SGL	Connate gas saturation, that is the smallest gas saturation in a gas saturation function table.
	SGCR	Critical gas saturation, that is the largest gas saturation for which the gas relative permeability is zero.
	SOGCR	Critical oil-in-gas saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-gas-connate water system.
Relative Permeability	KRG	Relative permeability of gas at the maximum gas saturation.
	KRGR	Relative permeability of gas at the residual oil saturation or the critical water saturation in a gas-water run.
	KRORG	Relative permeability of oil at the critical gas saturation.

Type	End-Point Keyword	Oil-Water End-Point Definitions
Capillary Pressure	SGLPC	Capillary pressure connate gas saturation, that is the smallest gas saturation in a gas saturation function table.

Table 8.46: HM Keyword List

See also the HMPROPS keyword in the PROPS section that allows the use of the ADD, BOX, EQUALS, COPY, MINVALUE, and MAXVALUE keywords to be used with the HA and HM series of keywords.

8.3.84 HMMROCK – HISTORY MATCH ROCK COMPRESSIBILITY GRADIENT CUMULATIVE MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HMMROCK defines the rock compressibility gradient cumulative multipliers to be applied to the rock compressibility as defined by the ROCK keyword in the PROPS section, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. The constant should be a real number.

The allocation of the ROCK tables to different grid blocks in the model is done via the PVTNUM or the SATNUM keywords in the REGION section.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

8.3.85 HMMROCKT – HISTORY MATCH ROCK COMPACTION GRADIENT CUMULATIVE MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HMMROCKT defines the rock compaction gradient cumulative multipliers to be applied to the compaction data entered by the ROCTAB or ROCKTABH keywords in the PRROPS section, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section

The ROCKTAB keyword defines the rock compaction attributes to be applied for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section. ROCKTAB defines pore volume and transmissibility multipliers versus pressure that are used in the compaction calculations. If the RKTRMDIR has been activated in the PROPS section, then the transmissibility multiplier is directional dependent

This keyword should only be used if compaction option has been enabled.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

8.3.86 HMPROPS – HISTORY MATCH END-POINT SECTION START

Description

HMPROPS defines the start of a history match end-points section, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. In addition, the End-Point Scaling option must also be activated by the ENDSCALE keyword which is also in the RUNSPEC section. The keyword allows for the BOX, EQUALS, COPY, MINVALUE, MAXVALUE and ADD keywords to be used with the HA and HM series of keywords that reference the end-point scaling arrays, that is: HMKRG, HMKRGR, HMKRO, HMKRORG, HMKRORW, HMKRW, HMKRWR, HMPCW, HMPCG, HMSGCR, HMSOWCR, HMSOGCR, HMSWCR, and HMSWL keywords.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.87 HMROCK – HISTORY MATCH ROCK COMPRESSIBILITY GRADIENT PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HMROCK keyword defines the history match rock compressibility gradient parameters for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section

See also the HMDIMS keyword in the RUNSPEC section that specifies the dimensions for the gradient option, including the maximum number of rock gradient parameters that can be used with the History Match Gradient option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.88 HMROCKT – HISTORY MATCH ROCK COMPACTION GRADIENT PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HMROCKT keyword defines the history match rock compaction gradient parameters for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section, and the history match rock compaction data has been entered via the HMMROCKT, ROCKTAB and ROCKTABH keywords in the PROPS section.

See also the HMDIMS keyword in the RUNSPEC section that specifies the dimensions for the gradient option, including the maximum number of rock gradient parameters that can be used with the History Match Gradient option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.89 HMRREF – HISTORY MATCH ROCK TABLE REFERENCE PRESSURE VALUES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HMRREF keyword defines the history match rock compaction reference pressure gradient values to be used in conjunction with HMMROCKT, ROCKTAB and ROCKTABH keywords in the PROPS section, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. The history match rock compaction data is entered via the HMMROCKT, ROCKTAB and ROCKTABH keywords in the PROPS section.

See also the HMDIMS keyword in the RUNSPEC section that specifies the dimensions for the gradient option, including the maximum number of rock gradient parameters that can be used with the History Match Gradient option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.90 HWKRO – END-POINT SCALING OF GRID CELL KRO(SWL) (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWKRO defines the scaling parameter for the oil relative permeability value at the connate water saturation (SWL), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil relative permeability in the high salinity water wet oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.91 HWKRORG – END-POINT SCALING OF GRID CELL KRO(SGCR) (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWKRORG defines the scaling parameter for the relative permeability of oil at the critical gas saturation (SGCR), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil relative permeability in the high salinity water wet oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.92 HWKRORW – END-POINT SCALING OF GRID CELL KRO(SWCR) (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWKRORW defines the scaling parameter for the relative permeability of oil at the critical water saturation (SWCR), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil relative permeability in the high salinity water wet oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.93 HWKRW – END-POINT SCALING OF GRID CELL KRW(SW =1.0) (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWKRW defines the scaling parameter at the maximum oil relative permeability value (SWU), that is for Sw = 1.0, for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water relative permeability in the high salinity water wet water relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.94 HWKRWR – END-POINT SCALING OF GRID CELL KRWR(SW=1.0) (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWKRWR defines the scaling parameter at the maximum oil relative permeability value (SWU), that is for Sw = 1.0, for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water relative permeability in the high salinity water wet water relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.95 HWPCW – END-POINT SCALING OF GRID CELL WATER CAPILLARY PRESSURE (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWPCW defines the maximum water-oil pressure values for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section. The keyword re-scales the oil-water capillary pressure in the high salinity water wet capillary saturation tables from a cell's assigned saturation function by the grid block's HWPCW value.

The capillary pressure for a grid block is scaled by:

$$P_c = P_{c_{TABLE}} \left(\frac{HWPCW}{P_{c_{TABLE-MAX}}} \right) \quad (8.57)$$

Where:

P_c	=	the resulting high salinity water wet water capillary pressure for a grid cell.
HWPCW	=	the maximum capillary pressure from the HWPCW array for a given cell.
$P_{c_{TABLE}}$	=	the capillary pressure in the high salinity water wet water capillary pressure table allocated to the grid block.
$P_{c_{TABLE-MAX}}$	=	the maximum capillary pressure in the high salinity water wet water capillary pressure table allocated to the grid block (that is at the connate water saturation).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.96 HWSOGCR – END-POINT SCALING GRID CELL SOGCR (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWSOGCR defines the critical oil saturation with respect to gas ("SOGCR"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil saturation in the high salinity water wet oil-gas relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.97 HWSOWCR – END-POINT SCALING GRID CELL SOWCR (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWSOWCR defines the critical oil saturation with respect to water ("SOWCR"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil saturation in the high salinity water wet water-oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.98 HWSWCR – END-POINT SCALING GRID CELL SWCR (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWSWCR defines the critical water saturation ("SWCR"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water saturation in the high salinity water wet water-oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.99 HWSWL – END-POINT SCALING GRID CELL SWL (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWSWL defines the connate water saturation ("SWL"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water saturation in the high salinity water wet water-oil relative permeability saturation tables, as well as the associated capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.100 HWSWLPC – END-POINT SCALING GRID CELL SWLPC (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWSWLPC defines the capillary pressure connate water saturation ("SWLPC"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water saturation in the high salinity water wet water-oil capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

Note the keyword only applies the scaling to the capillary pressures tables, unlike the HWSWL keyword that applies the scaling to both the capillary pressure and relative permeability tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.101 HWSWU – END-POINT SCALING GRID CELL SWU (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

HWSWU defines the maximum water saturation("SWU"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water saturation in the high salinity water wet water-oil relative permeability saturation tables, as well as the associated capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.102 HYDRHEAD – DEFINE HYDRAULIC HEAD OUTPUT REFERENCE DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HYDRHEAD keyword defines the hydraulic head reference data for when the hydraulic head information is requested to be written out via one on the SUMMARY keywords (BHD, BHDF, etc.) in the SUMMARY section, or to the RESTART file via the HYDH or HYDHFW variables on the RESTART keyword

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.103 HYMOBGDR – ACTIVATE CARLSON AND KILLOUGH ALTERNATIVE DRAINAGE HYSTERESIS OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, HYMOBGDR, activates the Carlson and Killough alternative secondary drainage hysteresis option for when the hysteresis option has been activated by the HYSTER variable on the SATOPTS keyword in the RUNSPEC section, and either the Carlson[196] or Killough[197] models have been selected via the EHYSTR keyword in the PROPS section. Due to numerical accuracy, the gas saturation may fall below the critical gas saturation (SGCR), that is the largest gas saturation for which the gas relative permeability is zero, and gas would therefore be immobile until the gas saturation increases above SGCR. This option overcomes this situation by letting the gas become mobile once it starts increasing, effectively setting the SGCR to the current gas saturation.

There is no data required for this keyword and there is no terminating "/" for this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Example

```
--
--       ACTIVATE CARLSON AND KILLOUGH ALTERNATIVE DRAINAGE HYSTERESIS OPTION
--
HYMOBGDR
```

8.3.104 HYSTCHCK - ACTIVATE HYSTERESIS IMBIBITION AND DRAINAGE END-POINT VALIDATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HYSTCHCK keyword activate the hysteresis imbibition and drainage end-point check to validate that the two sets of end-points are consistent, for when the Hysteresis option has been activated by the HYSTER variable on the SATOPTS keyword in the RUNSPEC section, and the ENDSCALE keyword in the RUNSPEC section has been activated to enable end-point scaling.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.105 IKRG – END-POINT SCALING OF GRID CELL KRG(SGU) (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

IKRG defines the imbibition scaling parameter at the maximum gas relative permeability value (ISGU), normally ISGU is equal to 1.0 - Swc, for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the Hysteresis option. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IKRG	IKRG is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling IKRG imbibition values for each cell in the model. Repeat counts may be used, for example 50*0.400. dimensionless			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the IKRGX±, IKRGY± and IKRGZ± series of the keywords should be used.

Table 8.47: IKRG Keyword Description

For the two point scaling option and for the IKRGR gas relative permeability array NOT present in the input deck the krg value for a grid block is scaled by:

$$k_{rg} = k_{rg\,TABLE}\left(\frac{IKRG}{k_{rg\,TABLE-MAX}}\right) \tag{8.58}$$

Where:

krg = the resulting krg value for a grid cell.
IKRG = the scaling gas relative permeability value from the IKRG array for a given cell.
$k_{rg\,TABLE}$ = the gas relative permeability from a grid block's gas-oil table at the grid blocks gas saturation.
$k_{rg\,TABLE-MAX}$ = the maximum gas relative permeability from a grid block's gas-oil table, that is at the connate water saturation (Swc).

If the IKRGR keyword is present in the input deck then the scaling matches the imbibition relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Phases Present	Critical Saturation
1	Gas-Oil	$S_{critical}$ = 1.0 – ISOGCR - ISWL
2	Gas-Oil-Water	$S_{critical}$ = 1.0 – ISOGCR - ISWL
3	Gas-Water	$S_{critical}$ = 1.0 – ISWCR

Table 8.48: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWUX, ISWUY and ISWUZ instead of ISWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWUX, ISWUX-, ISWUY, ISWUY-, ISWUZ and ISWUZ-, instead of the ISWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the IKRG, IKRGR, IKRO, IKRORG, IKRORW, IKRW and IKRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is IKRGX, IKRGY and IKRGZ instead of IKRG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is IKRGX, IKRGX-, IKRGY, IKRGY-,I KRGZ and IKRGZ-, instead of the IKRG keyword.

Example

The example below defines an input box for the whole grid and for layers one to three, for layer one IKRG is set equal to 0.550, for layer two IKRG equals 0.575, and for layer three IKRG equals 0.600.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET IKRG VALUES FOR THREE LAYERS IN THE MODEL
--
IKRG
         1000*0.550  1000*0.575  1000*0.600               /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

8.3.106 IKRGR – END-POINT SCALING OF GRID CELL KRGR(1-SOGCR) (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

IKRGR defines the imbibition scaling parameter at the relative permeability of gas at residual oil saturation (1 – ISOGCR), or critical water saturation in a gas-water run (Swc), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the Hysteresis option. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IKRGR	IKRGR is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned imbibition scaling IKRGR values for each cell in the model. In addition, for a given grid block IKGRGT should be less than IKRG. Repeat counts may be used, for example 50*0.400.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the IKRGRX± , IKRGRY± and IKRGRZ± series of the keywords should be used

Table 8.49: IKRGR Keyword Description

When the IKRGR keyword is present in the input deck then the scaling matches the imbibition relative permeability at the critical saturation of the displacing phase (oil or water).

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Phases Present	Critical Saturation
1	Gas-Oil	$S_{critical}$ = 1.0 – ISOGCR - ISWL
2	Gas-Oil-Water	$S_{critical}$ = 1.0 – ISOGCR - ISWL
3	Gas-Water	$S_{critical}$ = 1.0 – ISWCR

Table 8.50: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used,

that is ISWUX, ISWUY and ISWUZ instead of ISWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWUX, ISWUX-, ISWUY, ISWUY-, ISWUZ and ISWUZ-, instead of the ISWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the IKRG, IKRGR, IKRO, IKRORG, IKRORW, IKRW and IKRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is IKRGX, IKRGY and IKRGZ instead of IKRG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is IKRGX, IKRGX-, IKRGY, IKRGY-,I KRGZ and IKRGZ-, instead of the IKRG keyword.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one IKRRG is set equal to 0.500, for layer two IKRGR equals 0.570, and for layer three IKRGR equals 0.580.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET IKRGR VALUES FOR THREE LAYERS IN THE MODEL
--
IKRGR
         10000*0.500  10000*0.570  10000*0.580               /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The next example does exactly the same thing using the EQUALS keyword instead.

```
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         IKRGR'      0.5000       1*  1*   1*  1*    1   1  / IKRGR FOR LAYER 1
         IKRGR'      0.5700       1*  1*   1*  1*    2   2  / IKRGR FOR LAYER 2
         IKRGR'      0.5800       1*  1*   1*  1*    3   3  / IKRGR FOR LAYER 3
/
```

8.3.107 IKRO – END-POINT SCALING OF GRID CELL KRO(SWL) (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

IKRO defines the scaling parameter for the imbibition oil relative permeability value at the connate water saturation (ISWL), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the Hysteresis option. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IKRO	IKRO is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned imbibition scaling IKRO values for each cell in the model. Repeat counts may be used, for example 50*0.500.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the IKROX±, IKROY± and IKROZ± series of the keywords should be used.

Table 8.51: IKRO Keyword Description

For the two point scaling option and for the IKRORW or IKRORG oil imbibition relative permeability arrays NOT being present in the input deck the kro value for a grid block is scaled by:

$$k_{ro} = k_{ro\,TABLE}\left(\frac{IKRO}{k_{ro\,TABLE-MAX}}\right) \tag{8.59}$$

Where:

kro = the resulting kro value for a grid cell.
$IKRO$ = the scaling oil relative permeability value from the IKRO array for a given cell.
$k_{ro\,TABLE}$ = the oil relative permeability from a grid block's oil relative permeability table at the grid blocks oil saturation.
$k_{ro\,TABLE-MAX}$ = the maximum oil relative permeability from a grid block's oil relative table, that is at the critical water saturation (Swcr).

If the IKRORW or IKRORG keywords are present in the input deck then the scaling matches the relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Keywords Present	Critical Saturation
1	KRORW	$S_{critical}$ = 1.0 – SWCR - SGL
2	KRORG	$S_{critical}$ = 1.0 – SGCR - SWL

Table 8.52: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWUX, ISWUY and ISWUZ instead of ISWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWUX, ISWUX-, ISWUY, ISWUY-, ISWUZ and ISWUZ-, instead of the ISWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the IKRG, IKRGR, IKRO, IKRORG, IKRORW, IKRW and IKRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is IKRGX, IKRGY and IKRGZ instead of IKRG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is IKRGX, IKRGX-, IKRGY, IKRGY-,I KRGZ and IKRGZ-, instead of the IKRG keyword.

Example

The example below defines an input box for the whole grid and for layers one to three, for layer one IKRO is set equal to 0.850, for layer two IKRO equals 0.875, and for layer three IKRO equals 0.900.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          IKRO        0.8500        1*  1*   1*  1*    1   1  / IKRO FOR LAYER 1
          IKRO        0.8750        1*  1*   1*  1*    2   2  / IKRO FOR LAYER 2
          IKRO        0.9000        1*  1*   1*  1*    3   3  / IKRO FOR LAYER 3
/
```

8.3.108 IKRORG – END-POINT SCALING OF GRID CELL KRO(SGCR) (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

IKRORG defines the scaling parameter for the imbibition relative permeability of oil at the critical gas saturation (ISGCR), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the Hysteresis option. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IKRORG	IKRORG is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned imbibition scaling IKRORG values for each cell in the model. Repeat counts may be used, for example 50*0.850.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the IKRORGX±, IKRORGY± and IKRORGZ± series of the keywords should be used.

Table 8.53: IKRORG Keyword Description

When the IKRORG keyword is present in the input deck then the scaling matches the imbibition relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Keywords Present	Critical Saturation
1	IKRORW	$S_{critical}$ = 1.0 – ISWCR - ISGL
2	IKRORG	$S_{critical}$ = 1.0 – ISGCR - SWL

Table 8.54: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWUX, ISWUY and ISWUZ instead of ISWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible

versions of the aforementioned arrays should be used, that is ISWUX, ISWUX-, ISWUY, ISWUY-, ISWUZ and ISWUZ-, instead of the ISWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the IKRG, IKRGR, IKRO, IKRORG, IKRORW, IKRW and IKRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is IKRGX, IKRGY and IKRGZ instead of IKRG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is IKRGX, IKRGX-, IKRGY, IKRGY-,I KRGZ and IKRGZ-, instead of the IKRG keyword.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one IKRORG is set equal to 0.755, for layer two IKRORG equals 0.775, and for layer three IKRORG equals 0.800.

```

8.3.109 IKRORW – END-POINT SCALING OF GRID CELL KRO(SWCR) (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

IKRORW defines the scaling parameter for the imbibition relative permeability of oil at the critical water saturation (ISWCR), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the Hysteresis option. The SCALECRS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IKRORW	IKRORW is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned imbibition scaling IKRORW values for each cell in the model. Repeat counts may be used, for example 50*0.850			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the IKRORWX±, IKRORWY± and IKRORWZ± series of the keywords should be used.

Table 8.55: IKRORW Keyword Description

When the IKRORW keyword is present in the input deck then the scaling matches the imbibition relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Keywords Present	Critical Saturation
1	IKRORW	$S_{critical}$ = 1.0 – ISWCR - ISGL
2	IKRORG	$S_{critical}$ = 1.0 – ISGCR - ISWL

Table 8.56: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWUX, ISWUY and ISWUZ instead of ISWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible

versions of the aforementioned arrays should be used, that is ISWUX, ISWUX-, ISWUY, ISWUY-, ISWUZ and ISWUZ-, instead of the ISWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the IKRG, IKRGR, IKRO, IKRORG, IKRORW, IKRW and IKRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is IKRGX, IKRGY and IKRGZ instead of IKRG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is IKRGX, IKRGX-, IKRGY, IKRGY-,I KRGZ and IKRGZ-, instead of the IKRG keyword.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one IKRORW is set equal to 0.755, for layer two IKRORW equals 0.775, and for layer three IKRORW equals 0.800.

/
```

8.3.110 IKRW – END-POINT SCALING OF GRID CELL KRW(SW =1.0) (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

IKRW defines the scaling parameter at the maximum imbibition water relative permeability value (ISWU), that is for Sw = 1.0, for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the Hysteresis option. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IKRW	IKRW is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned imbibition scaling IKRW values for each cell in the model. Repeat counts may be used, for example 50*1.000.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the IKRWX±, IKRWY± and IKRWZ± series of the keywords should be used.

Table 8.57: IKRW Keyword Description

For the two point scaling option and for the IKRWR water relative permeability array NOT present in the input deck the krw value for a grid block is scaled by:

$$k_{rw} = k_{rw\,TABLE}\left(\frac{IKRW}{k_{rw\,TABLE-MAX}}\right) \tag{8.60}$$

Where:

krw = the resulting IKRW value for a grid cell.
$IKRW$ = the scaling water relative permeability value from the IKRW array for a given cell.
$k_{rw\,TABLE}$ = the water relative permeability from a grid block's oil relative permeability table at the grid blocks water saturation.
$k_{rw\,TABLE-MAX}$ = the maximum water relative permeability from a grid block's water relative table, that is at the maximum water saturation.

If the IKRWR keyword is present in the input deck then the scaling matches the imbibition relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Phases Present	Critical Saturation
1	Gas-Oil	$S_{critical}$ = 1.0 – ISOWCR - ISGL
2	Gas-Oil-Water	$S_{critical}$ = 1.0 – ISOWCR - ISGL
3	Gas-Water	$S_{critical}$ = 1.0 – ISGCR

Table 8.58: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWUX, ISWUY and ISWUZ instead of ISWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWUX, ISWUX-, ISWUY, ISWUY-, ISWUZ and ISWUZ-, instead of the ISWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the IKRG, IKRGR, IKRO, IKRORG, IKRORW, IKRW and IKRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is IKRGX, IKRGY and IKRGZ instead of IKRG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is IKRGX, IKRGX-, IKRGY, IKRGY-,I KRGZ and IKRGZ-, instead of the IKRG keyword.

Example

The example below defines an input box for the whole grid and for layers one to three, for layer one IKRW is set equal to 0.850, for layer two IKRW equals 0.875, and for layer three IKRW equals 0.900.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET IKRW VALUES FOR THREE LAYERS IN THE MODEL
--
IKRW
         10000*0.850  10000*0.875  10000*0.900               /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

8.3.111 IKRWR – END-POINT SCALING OF GRID CELL KRWR(SOWCR) (IMBIBITION)

Description

IKRWR defines the scaling parameter at the imbibition critical oil to water saturation value (ISOWCR), for the imbibition water relative permeability curve, for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the Hysteresis option. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IKRWR	IKRWR is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned imbibition scaling IKRWR values for each cell in the model. Repeat counts may be used, for example 50*1.000.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the IKRWRX±, IKRWRY± and IKRWRZ± series of the keywords should be used.

Table 8.59: IKRWR Keyword Description

When the IKRWR keyword is present in the input deck then the scaling matches the imbibition relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Phases Present	Critical Saturation
1	Gas-Oil	$S_{critical}$ = 1.0 – ISOWCR - ISGL
2	Gas-Oil-Water	$S_{critical}$ = 1.0 – ISOWCR - ISGL
3	Gas-Water	$S_{critical}$ = 1.0 – ISGCR

Table 8.60: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWUX, ISWUY and ISWUZ instead of ISWU, There is also the facility to make the directional end-

point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWUX, ISWUX-, ISWUY, ISWUY-, ISWUZ and ISWUZ-, instead of the ISWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the IKRG, IKRGR, IKRO, IKRORG, IKRORW, IKRW and IKRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is IKRGX, IKRGY and IKRGZ instead of IKRG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is IKRGX, IKRGX-, IKRGY, IKRGY-,I KRGZ and IKRGZ-, instead of the IKRG keyword.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one IKRWR is set equal to 0.755, for layer two IKRWR equals 0.775, and for layer three IKRWR equals 0.800.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET IKRWR VALUES FOR THREE LAYERS IN THE MODEL
--
IKRWR
         10000*0.755  10000*0.775  10000*0.800               /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The next example does exactly the same thing using the EQUALS keyword instead.

```
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         IKRWR       0.7550       1*  1*   1*  1*    1   1  / IKRWR FOR LAYER 1
         IKRWR       0.7750       1*  1*   1*  1*    2   2  / IKRWR FOR LAYER 2
         IKRWR       0.8000       1*  1*   1*  1*    3   3  / IKRWR FOR LAYER 3
/
```

8.3.112 IMKRVD – IMBIBITION RELATIVE PERMEABILITY END-POINTS VERSUS DEPTH FUNCTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the maximum imbibition oil, gas, and water relative permeability versus depth for the three phases. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the Hysteresis option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.113 IMPCVD – IMBIBITION MAXIMUM CAPILLARY PRESSURE VERSUS DEPTH FUNCTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the maximum imbibition gas-oil and water-oil capillary pressure values versus depth for when the end-point scaling option has been invoked by the ENDSCALE keyword in the RUNSPEC section and the HYSTER option on the SATOPTS keyword in the RUNSPEC section has been activated to invoke the Hysteresis option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.114 IMPORT – IMPORT GRID FILE DATA AT THE CURRENT POSITION

The IMPORT keyword informs the simulator to continue reading input data from the specified IMPORT file. When the end of the IMPORT file is reached, input data is read from the next keyword in the current file. Normally IMPORT files are generated by grid pre-processing software and the keyword allows for both formatted and unformatted (binary) files to be loaded.

See *IMPORT – Import Grid File Data at the Current Position* in the GRID section for a full description.

8.3.115 IMPTVD – IMBIBITION RELATIVE PERMEABILITY SATURATION END-POINTS VERSUS DEPTH

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the variation of the imbibition relative permeability saturation end-points (SWL, SWCR, etc.) for all three phases versus depth., for when the end-point scaling option has been invoked by the ENDSCALE keyword in the RUNSPEC section, and the HYSTER option on the SATOPTS keyword in the RUNSPEC section has been activated to invoke the Hysteresis option. This functionality is not supported in OPM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.116 IMSPCVD – IMBIBITION CAPILLARY PRESSURE CONNATE SATURATIONS VERSUS DEPTH

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the imbibition capillary pressure gas and water connate saturations values versus depth for when the end-point scaling option has been invoked by the ENDSCALE keyword in the RUNSPEC section, and the HYSTER option on the SATOPTS keyword in the RUNSPEC section has been activated to invoke the Hysteresis option. This functionality is not supported in OPM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.117 INCLUDE – LOAD ANOTHER DATA FILE AT THE CURRENT POSITION

The INCLUDE keyword informs OPM Flow to continue reading input data from the specified INCLUDE file. When the end of the INCLUDE file is reached, or the ENDINC keyword is encountered in the included file, input data is read from the next keyword in the current file.

See *INCLUDE – Load Another Data File at the Current Position* in the GLOBAL section for a full description.

8.3.118 INTPC – ACTIVATE DUAL POROSITY INTEGRATED CAPILLARY PRESSURE OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The INTPC keyword activates the integrated capillary pressure option for the oil, gas or both phases, for when a Dual Porosity model has been activated by either the DUALPORO or DUALPERM keywords in the RUNSPEC section. In addition, the keyword can only be used if the Gravity Drainage option has been specified by either the GRAVDR or GRAVDRM in the RUNSPEC section. Basically, activating this feature results in the simulator adjusting the capillary pressure curves by integrating the matrix capillary pressure curves over the matrix block height to calculate the average saturation.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.119 IONXROCK - DEFINE ION EXCHANGE CONSTANT BY SATURATION TABLE REGIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The IONXROCK keyword activates ion exchange and defines the ion exchange constant by saturation table regions, for when the brine phase has been activated by the BRINE keyword and the Multi-Component Brine model, that allows for the water phase to have multiple water salinities, has been activated by the ECLMC keyword. Both keywords are in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.120 IONXSURF - DEFINE SURFACTANT ION EXCHANGE CONSTANT BY SATURATION TABLE REGIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The IONXROCK keyword activates ion exchange on surfactant micellae[198] and defines the ion exchange constant by surfactant equivalent molecular weight for saturation table regions, for when the brine and surfactant phases has been activated by the BRINE and SURFACT keywords, and the Multi-Component Brine model, that allows for the water phase to have multiple water salinities, has been activated by the ECLMC keyword. All three keywords are in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[198] *Particle of colloidal dimensions that exists in equilibrium with the molecules or ions in solution from which it is formed. A micella or micelle (plural micellae or micelles, respectively) is an aggregate (or supramolecular assembly) of surfactant molecules dispersed in a liquid colloid. A typical micella in aqueous solution forms an aggregate with the hydrophilic "head" regions in contact with surrounding solvent, sequestering the hydrophobic single-tail regions in the micella centre (https://en.wikipedia.org/wiki/Micelle).*

8.3.121 IPCG – END-POINT SCALING OF GRID CELL GAS CAPILLARY PRESSURE (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

IPCG defines the maximum imbibition gas-oil capillary pressure values for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the hysteresis option. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IPCG	IPCG is an array of positive real numbers assigning the maximum imbibition gas capillary pressure values for each cell in the model. Repeat counts may be used, for example 30*100.0.			
		psia	bars	atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 8.61: IPCG Keyword Description

The capillary pressure for a grid block is scaled by:

$$P_c = P_{c_{TABLE}} \left(\frac{IPCG}{P_{c_{TABLE-MAX}}} \right) \quad (8.61)$$

Where:

Pc = the resulting imbibition gas-oil capillary pressure for a grid cell.
$IPCG$ = the maximum capillary pressure from the IPCG array for a given cell.
$P_{c_{TABLE}}$ = the capillary pressure in the imbibition capillary pressure table allocated to the grid block.
$P_{c_{TABLE-MAX}}$ = the maximum capillary pressure in the imbibition capillary pressure table allocated to the grid block at $S_g = 1 - S_{wco}$.

See also the PCG keyword for the equivalent drainage functionality.

Example

```
--
--        DEFINE GRID BLOCK IPCG DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
IPCG
          100*50.0  100*75.0  100*125.0                                    /
```

The above example defines the IPCG for 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.122 IPCW – END-POINT SCALING OF GRID CELL WATER CAPILLARY PRESSURE (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

IPCW defines the maximum imbibition water-oil or water-gas capillary pressure values for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the HYSTER option on the SATOPTS keyword in the RUNSPEC section has to be activated to invoke the hysteresis option. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	IPCW	IPCW is an array of positive real numbers assigning the maximum imbibition water capillary pressure values for each cell in the model. Repeat counts may be used, for example 30*100.0.			
		psia	bars	atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 8.62: IPCW Keyword Description

The capillary pressure for a grid block is scaled by:

$$P_c = P_{c_{TABLE}} \left(\frac{IPCW}{P_{c_{TABLE-MAX}}} \right) \quad (8.62)$$

Where:

Pc = the resulting imbibition water capillary pressure for a grid cell.
$IPCW$ = the maximum capillary pressure from the IPCW array for a given cell.
$P_{c_{TABLE}}$ = the capillary pressure in the imbibition capillary pressure table allocated to the grid block.
$P_{c_{TABLE-MAX}}$ = the maximum capillary pressure in the imbibition capillary pressure table allocated to the grid block (that is at the connate water saturation).

See also the PCW keyword for the equivalent drainage functionality.

Example

```
--
--        DEFINE GRID BLOCK IPCW DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
IPCW
          100*50.0  100*75.0   100*125.0                                    /
```

The above example defines the IPCW for 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.123 ISGCR – END-POINT SCALING OF GRID CELL CRITICAL GAS SATURATION (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISGCR defines the imbibition critical gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The critical gas saturation is defined as the maximum gas saturation for which the gas relative permeability is zero in a two-phase relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISGCR	ISGCR is an array of real numbers assigning the critical gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.03			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the critical gas saturation used with the end-point scaling option. If directional end-point scaling has been activated then the ISGCRX± , ISGCRX± and ISGCRX± series of keywords should be used.

Table 8.63: ISGCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the IKRG, IKROG, IKROW and IKRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISGCRX, ISGCRY and ISGCRZ instead of ISGCR. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISGCRX, ISGCRX-, ISGCRY, ISGCRY-, ISGCRZ and ISGCRZ-, instead of the ISGCR keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT ISGCR DATA FOR CELLS (NX x NY x NZ = 300)
ISGCR
         300*0.050                                                          /
```

The above example defines a constant critical gas saturation of 0.05 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.124 ISGL – END-POINT SCALING OF GRID CELL CONNATE GAS SATURATION (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISGL defines the imbibition connate gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The connate gas saturation is defined as the minimum gas saturation in a two-phase gas relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISGL	ISGL is an array of real numbers assigning the connate gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.03 dimensionless			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the connate gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the ISGLX± , ISGLY± and ISGZ± series of keywords should be used.

Table 8.64: ISGL Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISGLX, ISGLY and ISGLZ instead of ISGL. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISGLX, ISGLX-, ISGLY, ISGLY-, ISGLZ and ISGLZ-, instead of the ISGL keyword.

Example

```
--
--        DEFINE GRID BLOCK END-POINT ISGL DATA FOR ALL CELLS (NX x NY x NZ = 300)
ISGL
          300*0.030                                                              /
```

The above example defines a constant connate gas saturation of 0.03 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.125 ISGLPC – END-POINT SCALING OF GRID CELL CAPILLARY PRESSURE CONNATE GAS SATURATION (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISGLPC defines the imbibition connate gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The connate gas saturation is defined as the minimum gas saturation in a two-phase gas relative permeability table. The keyword only applies the scaling to the imbibition capillary pressures tables, unlike the ISGL keyword that applies the scaling to both the capillary pressure and relative permeability tables. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISGLPC	ISGLPC is an array of real numbers assigning the connate gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. If ISGLPC is omitted from the input deck the values will be defaulted to those on the ISGL series of keywords. If the ISGL series of keywords are missing from the input deck then the values are taken from the cell allocated capillary pressure table. Repeat counts may be used, for example 30*0.03			Taken from SGL or from the cell allocated capillary pressure table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the connate gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the ISGLX± , ISGLY± and ISGZ± series of keywords should be used.

Table 8.65: ISGLPC Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISGLX, ISGLY and ISGLZ instead of ISGL or ISGLPC. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISGLX, ISGLX-, ISGLY, ISGLY-, ISGLZ and ISGLZ-, instead of the ISGL or ISGLPC keywords.

Missing Some Functionality - Use with Caution.

Example

```
--
--       DEFINE GRID BLOCK END-POINT ISGLPC DATA FOR ALL CELLS
-       (NX x NY x NZ = 300)
ISGLPC
         300*0.030                                                    /
```

The above example defines a constant connate gas saturation of 0.03 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.126 ISGU – END-POINT SCALING OF GRID CELL MAXIMUM GAS SATURATION (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISGU defines the imbibition maximum gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The maximum gas saturation is defined as the maximum gas saturation in a two-phase gas relative permeability table. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISGU	ISGU is an array of real numbers assigning the maximum gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.70			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the maximum gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the ISGUX± , ISGUX± and ISGU± series of keywords should be used.

Table 8.66: ISGU Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISGUX, ISGUY and ISGUZ instead of ISGU. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISGUX, ISGUX-, ISGUY, ISGUY-, ISGUZ and ISGUZ-, instead of the ISGU keyword.

Example

```
--
--        DEFINE GRID BLOCK END-POINT ISGU DATA FOR ALL CELLS (NX x NY x NZ = 300)
ISGU
          300*0.700                                                          /
```

The above example defines a constant connate gas saturation of 0.70 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.127 ISOGCR – END-POINT SCALING OF GRID CELL CRITICAL OIL SATURATION TO GAS (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISOGCR defines the imbibition critical oil saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The critical oil saturation with respect to gas is defined as the maximum oil saturation for which the oil relative permeability is zero in a two-phase gas-oil relative permeability table. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISOGCR	ISOGCR is an array of real numbers assigning the critical oil saturation with respect to gas values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.30			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the critical gas saturation used with the end-point scaling option. If directional end-point scaling has been activated then the ISOGCRX± , ISOGCRX± and ISOGCRX± series of keywords should be used.

Table 8.67: ISOGCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISOGCRX, ISOGCRY and ISOGCRZ instead of ISOGCR. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISOGCRX, ISOGCRX-, ISOGCRY, ISOGCRY-, ISOGCRZ and ISOGCRZ-, instead of the ISOGCR keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT ISOGCR DATA FOR ALL CELLS
--       (NX x NY x NZ = 300)
--
ISOGCR
         300*0.200                                                    /
```

The above example defines a constant critical gas saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.128 ISOWCR – END-POINT SCALING OF GRID CELL CRITICAL OIL SATURATION TO WATER (IMBIB.)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISOWCR defines the imbibition critical oil saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The critical oil saturation with respect to water is defined as the maximum oil saturation for which the oil relative permeability is zero in a two-phase oil-water relative permeability table. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISOWCR	ISOWCR is an array of real numbers assigning the critical oil saturation with respect to water values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.30			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the critical gas saturation used with the end-point scaling option. If directional end-point scaling has been activated then the ISOWCRX± , ISOWCRX± and ISOWCRX± series of keywords should be used.

Table 8.68: ISOWCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISOWCRX, ISOWCRY and ISOWCRZ instead of ISOWCR. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISOWCRX, ISOWCRX-, ISOWCRY, ISOWCRY-, ISOWCRZ and ISOWCRZ-, instead of the ISOWCR keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT ISOWCR DATA FOR ALL CELLS
--       (NX x NY x NZ = 300)
--
ISOWCR
         300*0.200                                                    /
```

The above example defines a constant critical gas saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section

8.3.129 ISWCR – END-POINT SCALING OF GRID CELL CRITICAL WATER SATURATION (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISWCR defines the imbibition critical water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The critical water saturation is defined as the maximum water saturation for which the water relative permeability is zero in a two-phase relative permeability table. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISWCR	ISWCR is an array of real numbers assigning the critical water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.20			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the critical water saturation used with the end-point scaling option. If directional end-point scaling has been activated then the ISWCRX± , ISWCRX± and ISWCRX± series of keywords should be used.

Table 8.69: ISWCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWCRX, ISWCRY and ISWCRZ instead of ISWCR. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWCRX, ISWCRX-, ISWCRY, ISWCRY-, ISWCRZ and ISWCRZ-, instead of the ISWCR keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT ISWCR DATA FOR ALL CELLS
--       (NX x NY x NZ = 300)
--
ISWCR
  300*0.200                                                    /
```

The above example defines a constant critical water saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.130 ISWL – END-POINT SCALING OF GRID CELL CONNATE WATER SATURATION (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISWL defines the imbibition connate water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The connate water saturation is defined as the minimum water saturation in a two-phase water relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISWL	ISWL is an array of real numbers assigning the connate water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.15			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the connate gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the ISWLX± , ISWLY± and ISWZ± series of keywords should be used.

Table 8.70: ISWL Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWLX, ISWLY and ISWLZ instead of ISWL. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWLX, ISWLX-, ISWLY, ISWLY-, ISWLZ and ISWLZ-, instead of the ISWL keyword.

Example

```
--
--        DEFINE GRID BLOCK END-POINT ISWL DATA FOR ALL CELLS (NX x NY x NZ = 300)
--
ISWL
          300*0.150                                                              /
```

The above example defines a constant connate water saturation of 0.15 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.131 ISWLPC – END-POINT SCALING GRID CELL CAPILLARY PRESSURE CONNATE WATER SATURATIONS (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISWLPC defines the imbibition connate water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The connate water saturation is defined as the minimum water saturation in a two-phase water relative permeability table. The keyword only applies the scaling to the imbibition capillary pressures tables, unlike the ISWL keyword that applies the scaling to both the capillary pressure and relative permeability tables. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISWLPC	ISWLPC is an array of real numbers assigning the connate water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. If ISWLPC is omitted from the input deck the values will be defaulted to those on the ISGL series of keywords. If the ISWL series of keywords are missing from the input deck then the values are taken from the cell allocated capillary pressure table. Repeat counts may be used, for example 30*0.15			Taken from SWL or from the cell allocated capillary pressure table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the connate gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the ISWLX± , ISWLY± and ISWZ± series of keywords should be used.

Table 8.71: ISWLPC Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWLX, ISWLY and ISWLZ instead of ISWL or ISWLPC. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWLX, ISWLX-, ISWLY, ISWLY-, ISWLZ and ISWLZ-, instead of the ISWL or ISWLPC keywords.

Missing Some Functionality - Use with Caution.

Example

```
--
--      DEFINE GRID BLOCK END-POINT ISWLPC DATA FOR ALL CELLS (
--      NX x NY x NZ = 300)
--
ISWLPC
         300*0.150                                                              /
```

The above example defines a constant connate water saturation of 0.15 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.132 ISWU – END-POINT SCALING OF GRID CELL MAXIMUM WATER SATURATION (IMBIBITION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ISWU defines the imbibition maximum water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE in the RUNSPEC section and the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section. The maximum water saturation is defined as the maximum water saturation in a two-phase water relative permeability table. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ISWU	ISWU is an array of real numbers assigning the maximum water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.70			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the maximum water saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the ISWUX± , ISWUX± and ISWU± series of keywords should be used.

Table 8.72: ISWU Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the ISWL, ISWCR, ISWU, ISGL, ISGCR, ISGU, ISOWCR, and ISOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is ISWUX, ISWUY and ISWUZ instead of ISWU. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is ISWUX, ISWUX-, ISWUY, ISWUY-, ISWUZ and ISWUZ-, instead of the ISWU keyword.

Example

```
--
--        DEFINE GRID BLOCK END-POINT ISWU DATA FOR ALL CELLS (NX x NY x NZ = 300)
--
ISWU
          300*0.700                                                              /
```

The above example defines a constant connate gas saturation of 0.70 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.133 KRG – END-POINT SCALING OF GRID CELL KRG(SGU) (DRAINAGE)

Description

KRG defines the scaling parameter at the maximum drainage gas relative permeability value (SGU), normally SGU is equal to 1.0 - Swc, for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	KRG	KRG is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling KRG values for each cell in the model. Repeat counts may be used, for example 50*0.400. dimensionless			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the KRGX±, KRGY± and KRGZ± series of the keywords should be used.

Table 8.73: KRG Keyword Description

For the two point scaling option and for the KRGR gas relative permeability array NOT present in the input deck the krg value for a grid block is scaled by:

$$k_{rg} = k_{rg\,TABLE}\left(\frac{KRG}{k_{rg\,TABLE-MAX}}\right) \quad (8.63)$$

Where:

krg = the resulting krg value for a grid cell.
KRG = the scaling gas relative permeability value from the KRG array for a given cell.
$k_{rg\,TABLE}$ = the gas relative permeability from a grid block's gas-oil table at the grid blocks gas saturation.
$k_{rg\,TABLE-MAX}$ = the maximum gas relative permeability from a grid block's gas-oil table, that is at the connate water saturation (Swc).

If the KRGR keyword is present in the input deck then the scaling matches the relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Phases Present	Critical Saturation
1	Gas-Oil	$S_{critical}$ = 1.0 – SOGCR - SWL
2	Gas-Oil-Water	$S_{critical}$ = 1.0 – SOGCR - SWL
3	Gas-Water	$S_{critical}$ = 1.0 – SWCR

Table 8.74: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWUX, SWUY and SWUZ instead of SWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWUX, SWUX-, SWUY, SWUY-, SWUZ and SWUZ-, instead of the SWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the KRG, KRGR, KRO, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is KRGX, KRGY and KRGZ instead of KRG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is KRGX, KRGX-, KRGY, KRGY-, KRGZ and KRGZ-, instead of the KRG keyword.

If the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section, then the equivalent imbibition arrays prefixed with the letter I, for example IKRG, can be used to scale KRG for the relative permeability imbibition tables.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one KRG is set equal to 0.555, for layer two KRG equals 0.575, and for layer three KRG equals 0.600.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET KRG VALUES FOR THREE LAYERS IN THE MODEL
--
KRG
         10000*0.555  10000*0.575  10000*0.600              /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The next example does exactly the same thing using the EQUALS keyword instead.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------

8.3.134 KRGR – END-POINT SCALING OF GRID CELL KRGR(1-SOGCR) (DRAINAGE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

KRGR defines the scaling parameter at the relative permeability of gas at residual oil saturation (1 – SOGCR), or critical water saturation in a gas-water run (Swc), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	KRGR	KRGR is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling KRGR values for each cell in the model. In addition, for a given grid block KGRG should be less than KRG. Repeat counts may be used, for example 50*0.400.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the KRGRX± , KRGRY± and KRGRZ± series of the keywords should be used.

Table 8.75: KRGR Keyword Description

When the KRGR keyword is present in the input deck then the scaling matches the relative permeability at the critical saturation of the displacing phase (oil or water).

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Phases Present	Critical Saturation
1	Gas-Oil	$S_{critical}$ = 1.0 – SOGCR - SWL
2	Gas-Oil-Water	$S_{critical}$ = 1.0 – SOGCR - SWL
3	Gas-Water	$S_{critical}$ = 1.0 – SWCR

Table 8.76: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWUX, SWUY and SWUZ instead of SWU, There is also the facility to make the directional end-point

scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWUX, SWUX-, SWUY, SWUY-, SWUZ and SWUZ-, instead of the SWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the KRG, KRGR, KRO, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is KRGRX, KRGRY and KRGRZ instead of KRGR, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is KRGRX, KRGRX-, KRGRY, KRGRY-, KRGRZ and KRGRZ-, instead of the KRGR keyword.

If the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section, then the equivalent imbibition arrays suffixed with the letter I, for example IKRGR, can be used to define the KRGR for the relative permeability imbibition tables.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one KRGR is set equal to 0.500, for layer two KRGR equals 0.570, and for layer three KRGR equals 0.580.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)

BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET KRGR VALUES FOR THREE LAYERS IN THE MODEL
--
KRGR
         10000*0.500  10000*0.570  10000*0.580              /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The next example does exactly the same thing using the EQUALS keyword instead.

```
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         KRGR        0.5000       1*  1*   1*  1*    1   1  / KRGR FOR LAYER 1
         KRGR        0.5700       1*  1*   1*  1*    2   2  / KRGR FOR LAYER 2
         KRGR        0.5800       1*  1*   1*  1*    3   3  / KRGR FOR LAYER 3
/
```

8.3.135 KRO – END-POINT SCALING OF GRID CELL KRO(SWL) (DRAINAGE)

Description

KRO defines the scaling parameter for the drainage oil relative permeability value at the connate water saturation (SWL), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	KRO	KRO is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling KRO values for each cell in the model. Repeat counts may be used, for example 50*0.500.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the KROX±, KROY± and KROZ± series of the keywords should be used.

Table 8.77: KRO Keyword Description

For the two point scaling option and for the KRORW or KRORG oil relative permeability arrays NOT being present in the input deck the kro value for a grid block is scaled by:

$$k_{ro} = k_{ro\,TABLE}\left(\frac{KRO}{k_{ro\,TABLE-MAX}}\right) \quad (8.64)$$

Where:

kro = the resulting kro value for a grid cell.
KRO = the scaling oil relative permeability value from the KRO array for a given cell.
$k_{ro\,TABLE}$ = the oil relative permeability from a grid block's oil relative permeability table at the grid blocks oil saturation.
$k_{ro\,TABLE-MAX}$ = the maximum oil relative permeability from a grid block's oil relative table, that is at the critical water saturation (Swcr).

If the KRORW or KRORG keywords are present in the input deck then the scaling matches the relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Keywords Present	Critical Saturation
1	KRORW	$S_{critical}$ = 1.0 – SWCR - SGL
2	KRORG	$S_{critical}$ = 1.0 – SGCR - SWL

Table 8.78: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWUX, SWUY and SWUZ instead of SWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWUX, SWUX-, SWUY, SWUY-, SWUZ and SWUZ-, instead of the SWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the KRG, KRGR, KRO, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is KROX, KROY and KROZ instead of KRO, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is KROX, KROX-, KROY, KROY-, KROZ and KROZ-, instead of the KRO keyword.

If the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section, then the equivalent imbibition arrays suffixed with the letter I, for example IKRO, can be used to define the KRO for the relative permeability imbibition tables.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one KRO is set equal to 0.855, for layer two KRO equals 0.875, and for layer three KRO equals 0.900.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET KRO VALUES FOR THREE LAYERS IN THE MODEL
--
KRO
         10000*0.855  10000*0.875  10000*0.900              /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The next example does exactly the same thing using the EQUALS keyword instead.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          KRO         0.8550        1*  1*   1*  1*    1   1  / KRO FOR LAYER 1
          KOG         0.8750        1*  1*   1*  1*    2   2  / KRO FOR LAYER 2
          KRO         0.9000        1*  1*   1*  1*    3   3  / KRO FOR LAYER 3
/
```

8.3.136 KRORG – END-POINT SCALING OF GRID CELL KRO(SGCR) (DRAINAGE)

Description

KRORG defines the scaling parameter for the drainage relative permeability of oil at the critical gas saturation (SGCR), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	KRORG	KRORG is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling KRORG values for each cell in the model. Repeat counts may be used, for example 50*0.850.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the KRORGX±, KRORGY± and KRORGZ± series of the keywords should be used.

Table 8.79: KRORG Keyword Description

When the KRORG keyword is present in the input deck then the scaling matches the relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Keywords Present	Critical Saturation
1	KRORW	$S_{critical}$ = 1.0 – SWCR - SGL
2	KRORG	$S_{critical}$ = 1.0 – SGCR - SWL

Table 8.80: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWUX, SWUY and SWUZ instead of SWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWUX, SWUX-, SWUY, SWUY-, SWUZ and SWUZ-, instead of the SWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the KRG, KRGR, KRORG, KRORGRG, KRORGRW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is KRORGX, KRORGY and KRORGZ instead of KRORG, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is KRORGX, KRORGX-, KRORGY, KRORGY-, KRORGZ and KRORGZ-, instead of the KRORG keyword.

If the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section, then the equivalent imbibition arrays suffixed with the letter I, for example IKRORG, can be used to define the KRORG for the relative permeability imbibition tables.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one KRORG is set equal to 0.755, for layer two KRORG equals 0.775, and for layer three KRORG equals 0.800.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------

         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET KRORG VALUES FOR THREE LAYERS IN THE MODEL
--
KRORG
         10000*0.755  10000*0.775  10000*0.800               /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The next example does exactly the same thing using the EQUALS keyword instead.

```
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         KRORG       0.7550       1*  1*   1*  1*    1   1  / KRORG FOR LAYER 1
         KRORG       0.7750       1*  1*   1*  1*    2   2  / KRORG FOR LAYER 2
         KRORG       0.8000       1*  1*   1*  1*    3   3  / KRORG FOR LAYER 3
/
```

8.3.137 KRORW – END-POINT SCALING OF GRID CELL KRO(SWCR) (DRAINAGE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

KRORW defines the scaling parameter for the drainage relative permeability of oil at the critical water saturation (SWCR), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The SCALECRS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	KRORW	KRORW is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling KRORW values for each cell in the model. Repeat counts may be used, for example 50*0.850			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the KRORWX±, KRORWY± and KRORWZ± series of the keywords should be used.

Table 8.81: KRORW Keyword Description

When the KRORW keyword is present in the input deck then the scaling matches the relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Keywords Present	Critical Saturation
1	KRORW	$S_{critical}$ = 1.0 – SWCR - SGL
2	KRORG	$S_{critical}$ = 1.0 – SGCR - SWL

Table 8.82: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWUX, SWUY and SWUZ instead of SWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of

the aforementioned arrays should be used, that is SWUX, SWUX-, SWUY, SWUY-, SWUZ and SWUZ-, instead of the SWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the KRG, KRGR, KRORW, KRORWRG, KRORWRW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is KRORWX, KRORWY and KRORWZ instead of KRORW, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is KRORWX, KRORWX-, KRORWY, KRORWY-, KRORWZ and KRORWZ-, instead of the KRORW keyword.

If the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section, then the equivalent imbibition arrays suffixed with the letter I, for example IKRORW, can be used to define the KRORW for the relative permeability imbibition tables.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one KRORW is set equal to 0.755, for layer two KRORW equals 0.775, and for layer three KRORW equals 0.800.

```

```

8.3.138 KRW – END-POINT SCALING OF GRID CELL KRW(SW =1.0) (DRAINAGE)

Description

KRW defines the scaling parameter at the maximum drainage water relative permeability value (SWU), that is for Sw = 1.0, for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	KRW	KRW is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling KRW values for each cell in the model. Repeat counts may be used, for example 50*1.000.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the KRWX±, KRWY± and KRWZ± series of the keywords should be used.

Table 8.83: KRW Keyword Description

For the two point scaling option and for the KRWR water relative permeability array NOT present in the input deck the krw value for a grid block is scaled by:

$$k_{rw} = k_{rw\,TABLE}\left(\frac{KRW}{k_{rw\,TABLE-MAX}}\right) \tag{8.65}$$

Where:

krw = the resulting KRW value for a grid cell.
KRW = the scaling water relative permeability value from the KRW array for a given cell.
$k_{rw\,TABLE}$ = the water relative permeability from a grid block's oil relative permeability table at the grid blocks water saturation.
$k_{rw\,TABLE-MAX}$ = the maximum water relative permeability from a grid block's water relative table, that is at the maximum water saturation.

If the KRWR keyword is present in the input deck then the scaling matches the relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Phases Present	Critical Saturation
1	Gas-Oil	$S_{critical}$ = 1.0 – SOWCR - SGL
2	Gas-Oil-Water	$S_{critical}$ = 1.0 – SOWCR - SGL
3	Gas-Water	$S_{critical}$ = 1.0 – SGCR

Table 8.84: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWUX, SWUY and SWUZ instead of SWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWUX, SWUX-, SWUY, SWUY-, SWUZ and SWUZ-, instead of the SWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the KRG, KRGR, KRW, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is KRWX, KRWY and KRWZ instead of KRW, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is KRWX, KRWX-, KRWY, KRWY-, KRWZ and KRWZ-, instead of the KRW keyword.

If the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section, then the equivalent imbibition arrays suffixed with the letter I, for example IKRW, can be used to define the KRW for the relative permeability imbibition tables.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one KRW is set equal to 0.855, for layer two KRW equals 0.875, and for layer three KRW equals 0.900.

```

8.3.139 KRWR – END-POINT SCALING OF GRID CELL KRWR(SOWCR) (DRAINAGE)

Description

KRWR defines the scaling parameter at the drainage critical oil to water saturation value (SOWCR), for the drainage water relative permeability curve, for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The SCALCERS keyword in the PROPS section defines the options used in the re-scaling process, the options are two point scaling and three point scaling.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	KRWR	KRWR is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling KRWR values for each cell in the model. Repeat counts may be used, for example 50*1.000.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) Note this the directional independent version of the keyword used with the end-point scaling option. If directional end-point scaling has been activated then the KRWRX±, KRWRY± and KRWRZ± series of the keywords should be used.

Table 8.85: KRWR Keyword Description

When the KRWR keyword is present in the input deck then the scaling matches the relative permeability at the critical saturation of the displacing phase.

If three point scaling option has been selected via the SCALECRS keyword in the PROPS section the critical displacing phase is defined as:

No	Phases Present	Critical Saturation
1	Gas-Oil	$S_{critical}$ = 1.0 – SOWCR - SGL
2	Gas-Oil-Water	$S_{critical}$ = 1.0 – SOWCR - SGL
3	Gas-Water	$S_{critical}$ = 1.0 – SGCR

Table 8.86: Critical Displacement Relationships

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWUX, SWUY and SWUZ instead of SWU, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of

the aforementioned arrays should be used, that is SWUX, SWUX-, SWUY, SWUY-, SWUZ and SWUZ-, instead of the SWU keyword.

End-point scaling also allows the entered relative permeability functions to be scale on the relative permeability values using the KRG, KRGR, KRWR, KRORG, KRORW, KRWR and KRWRR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is KRWRX, KRWRY and KRWRZ instead of KRWR, There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is KRWRX, KRWRX-, KRWRY, KRWRY-, KRWRZ and KRWRZ-, instead of the KRWR keyword.

If the hysteresis model option has been activated on the SATOPTS keyword in the RUNSPEC section, then the equivalent imbibition arrays suffixed with the letter I, for example IKRWR, can be used to define the KRWR for the relative permeability imbibition tables.

Examples

The first example defines an input box for the whole grid and for layers one to three, for layer one KRWR is set equal to 0.755, for layer two KRWR equals 0.775, and for layer three KRWR equals 0.800.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET KRWR VALUES FOR THREE LAYERS IN THE MODEL
--
KRWR
         10000*0.755  10000*0.775  10000*0.800               /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

The next example does exactly the same thing using the EQUALS keyword instead.

```
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         KRWR        0.7550       1*  1*   1*  1*    1   1  / KRWR FOR LAYER 1
         KRWR        0.7750       1*  1*   1*  1*    2   2  / KRWR FOR LAYER 2
         KRWR        0.8000       1*  1*   1*  1*    3   3  / KRWR FOR LAYER 3
/
```

8.3.140 LANGMPL – DEFINE LANGMUIR PRESSURE GRID CELL MULTIPLIER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, LANGMPL, defines the coal bed methane Langmuir Adsorption[199] pressure multiplier for each grid block, for when the Coal Bed Methane option has been activated via the COAL keyword in the RUNSPEC section. The keyword applies the multiplier to the pressure values in a cell's allocated Langmuir table when calculating a cell's adsorption capacity. See the LANGMUIR keyword in the PROPS section for specifying the Langmuir tables for the model.

Note that if he Dual Porosity model has been activated by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section, then LANGMPL applies to only the matrix grid block.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[199] *Langmuir, Irving (June 1918). "The Adsorption of Gases on Plane Surface of Glass, Mica and Platinum". The Research Laboratory of the General Electric Company. 40 (9): 1361–1402. doi:10.1021/ja02242a004*

8.3.141 LANGMUIR – LANGMUIR ADSORPTION ISOTHERM TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LANGMUIR keyword defines the coal bed methane Langmuir Adsorption Isotherms[200] tables, for when the Coal Bed Methane option has been activated via the COAL keyword in the RUNSPEC section. See the COALNUM keyword in the GRID section for allocating the Langmuir tables to the grid blocks and also the LANGMPL keyword in the PROPS section for re-scaling the pressure values in the tables that are allocated to a cell.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[200] *Langmuir, Irving (June 1918). "The Adsorption of Gases on Plane Surface of Glass, Mica and Platinum". The Research Laboratory of the General Electric Company. 40 (9): 1361–1402. doi:10.1021/ja02242a004*

8.3.142 LANGSOLV – LANGMUIR ADSORPTION ISOTHERM SOLVENT TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LANGMUIR keyword defines the coal bed methane Langmuir Adsorption Isotherms[201] Solvent tables, for when the Coal Bed Methane option has been activated via the COAL keyword and the Solvent phase has been declared by the SOLVENT keyword in the RUNSPEC section. See the COALNUM keyword in the GRID section for allocating the Langmuir solvent tables to the grid blocks, and also the LANGMUIR keyword in the PROPS section for defining the Langmuir Adsorption Isotherm tables. Keywords COALADS and COALPP, also in the PROPS section, are used to specify the relative adsorption data in runs containing the solvent phase.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[201] *Langmuir, Irving (June 1918). "The Adsorption of Gases on Plane Surface of Glass, Mica and Platinum". The Research Laboratory of the General Electric Company. 40 (9): 1361–1402. doi:10.1021/ja02242a004*

8.3.143 LCUNIT – DEFINE LINEAR COMBINATION RATE AND VOLUME UNITS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LCUNIT keyword defines the units for the Linear Combination facility which allows for a linear combination of oil, gas and water rates and volumes to be used as combination targets and constraints in controlling group and well production and injection data. See also the LINCOM in the SCHEDULE section that defines the actual linear combination equation.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.144 LKRO – END-POINT SCALING OF GRID CELL KRO(SWL) (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LKRO defines the scaling parameter for the oil relative permeability value at the connate water saturation (SWL), for all the cells in the model via an array, for when the Low Salt option and the End-point Scaling options has been activated by the LOWSALT and the ENDSCALE keywords in the RUNSPEC section. The data is used to scale the oil relative permeability in the low salinity oil wet oil relative permeability saturation tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.145 LKRORG – END-POINT SCALING OF GRID CELL KRO(SGCR) (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LKRORG defines the scaling parameter for the relative permeability of oil at the critical gas saturation (SGCR), for all the cells in the model via an array, for when the Low Salt option and the End-point Scaling options has been activated by the LOWSALT and the ENDSCALE keywords in the RUNSPEC section. The data is used to scale the oil relative permeability in the low salinity oil wet oil relative permeability saturation tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.146 LKRORW – END-POINT SCALING OF GRID CELL KRO(SWCR) (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LKRORW defines the scaling parameter for the relative permeability of oil at the critical water saturation (SWCR), for all the cells in the model via an array, for when the Low Salt option and the End-point Scaling options has been activated by the LOWSALT and the ENDSCALE keywords in the RUNSPEC section. The data is used to scale the oil relative permeability in the low salinity oil wet oil relative permeability saturation tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.147 LKRW – END-POINT SCALING OF GRID CELL KRW(SW =1.0) (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LKRW defines the scaling parameter at the maximum oil relative permeability value (SWU), that is for Sw = 1.0, for all the cells in the model via an array, for when the Low Salt option and the End-point Scaling options has been activated by the LOWSALT and the ENDSCALE keywords in the RUNSPEC section. The data is used to scale the water relative permeability in the low salinity oil wet water relative permeability saturation tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.148 LKRWR – END-POINT SCALING OF GRID CELL KRWR(SOWCR) (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LKRWR defines the scaling parameter at the maximum oil relative permeability value (SWU), that is for Sw = 1.0, for all the cells in the model via an array, for when the Low Salt option and the End-point Scaling options has been activated by the LOWSALT and the ENDSCALE keywords in the RUNSPEC section. The data is used to scale the water relative permeability in the low salinity oil wet water relative permeability saturation tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.149 LPCW – END-POINT SCALING OF GRID CELL WATER CAPILLARY PRESSURE (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LPCW defines the maximum oil-water pressure values for all the cells in the model via an array, for when the Low Salt option and the End-point Scaling options has been activated by the LOWSALT and the ENDSCALE keywords in the RUNSPEC section. The keyword re-scales the oil-water capillary pressure in the low salinity oil wet capillary saturation tables from a cell's assigned saturation function by the grid block's LPCW value.

The capillary pressure for a grid block is scaled by:

$$P_c = P_{c_{TABLE}} \left(\frac{LPCW}{P_{c_{TABLE-MAX}}} \right) \tag{8.66}$$

Where:

P_c = the resulting low salt oil wet water capillary pressure for a grid cell.

$LPCW$ = the maximum capillary pressure from the LPCW array for a given cell.

$P_{c_{TABLE}}$ = the capillary pressure in the low salt oil wet capillary pressure table allocated to the grid block.

$P_{c_{TABLE-MAX}}$ = the maximum capillary pressure in the low salt oil capillary pressure table allocated to the grid block (that is at the connate water saturation).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.150 LSALTFNC - DEFINE LOW SALT WEIGHTING FACTORS VERSUS SALT CONCENTRATION FUNCTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LSALTFNC keyword defines the low salt weighting factors versus salt concentration functions for when the Low Salt option has been activated by the LOWSALT keyword in the RUNSPEC section. The tables are used to modify the oil and water relative permeability saturation end-points, as well as the water-oil capillary pressure end-points, for different salt concentrations within a grid cell.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.151 LSOGCR – END-POINT SCALING GRID CELL SOGCR (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LSOGCR defines the critical oil saturation with respect to gas ("SOGCR"), for all the cells in the model via an array, for when the Low Salt option has been selected. The data is used to scale the oil saturation in the low salinity oil wet oil-gas relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.152 LSOWCR – END-POINT SCALING GRID CELL SOWCR (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LSOWCR defines the critical oil saturation with respect to water ("SOWCR"), for all the cells in the model via an array, for when the Low Salt option has been selected. The data is used to scale the oil saturation in the low salinity oil wet water-oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.153 LSWCR – END-POINT SCALING GRID CELL SWCR (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LSWCR defines the critical water saturation ("SWCR"), for all the cells in the model via an array, for when the Low Salt option has been selected. The data is used to scale the water saturation in the low salinity oil wet water-oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.154 LSWL – END-POINT SCALING GRID CELL SWL (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LSWL defines the connate water saturation ("SWL"), for all the cells in the model via an array, for when the Low Salt option has been selected. The data is used to scale the water saturation in the low salinity oil wet water-oil relative permeability saturation tables, as well as the associated capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.155 LSWLPC – END-POINT SCALING GRID CELL SWLPC (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LSWLPC defines the capillary pressure connate water saturation ("SWLPC"), for all the cells in the model via an array, for when the Low Salt option has been selected. The data is used to scale the water saturation in the low salinity oil wet water-oil capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section.

Note the keyword only applies the scaling to the capillary pressures tables, unlike the LSWL keyword that applies the scaling to both the capillary pressure and relative permeability tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.156 LSWU – END-POINT SCALING GRID CELL SWU (LOW SALINITY AND OIL WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LSWU defines the maximum water saturation("SWU"), for all the cells in the model via an array, for when the Low Salt option has been selected. The data is used to scale the water saturation in the low salinity oil wet water-oil relative permeability saturation tables, as well as the associated capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.157 LWKRO – END-POINT SCALING OF GRID CELL KRO(SWL) (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWKRO defines the scaling parameter for the oil relative permeability value at the connate water saturation (SWL), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil relative permeability in the low salinity water wet oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.158 LWKRORG – END-POINT SCALING OF GRID CELL KRO(SGCR) (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWKRORG defines the scaling parameter for the relative permeability of oil at the critical gas saturation (SGCR), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil relative permeability in the low salinity water wet oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.159 LWKRORW – END-POINT SCALING OF GRID CELL KRO(SWCR) (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWKRORW defines the scaling parameter for the relative permeability of oil at the critical water saturation (SWCR), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil relative permeability in the low salinity water wet oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.160 LWKRW – END-POINT SCALING OF GRID CELL KRW(SW =1.0) (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWKRW defines the scaling parameter at the maximum water relative permeability value (SWU), that is for Sw = 1.0, for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water relative permeability in the low salinity water wet water relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.161 LWKRWR – END-POINT SCALING OF GRID CELL KRWR(SW=1.0) (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWKRWR defines the scaling parameter at the critical oil to water saturation value (SOWCR), for the water relative permeability curve, for all the cells in the model via an array, and for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water relative permeability in the low salinity water wet water relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.162 LWPCW – END-POINT SCALING OF GRID CELL WATER CAPILLARY PRESSURE (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWPCW defines the maximum water-oil pressure values for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section. The keyword re-scales the oil-water capillary pressure in the low salinity water wet capillary saturation tables from the cell's assigned saturation function by the grid block's LWPCW value.

The capillary pressure for a grid block is scaled by:

$$P_c = P_{c_{TABLE}} \left(\frac{HWPCW}{P_{c_{TABLE-MAX}}} \right) \tag{8.67}$$

Where:

P_c = the resulting high salinity water wet water capillary pressure for a grid cell.

$HWPCW$ = the maximum capillary pressure from the HWPCW array for a given cell.

$P_{c_{TABLE}}$ = the capillary pressure in the high salinity water wet water capillary pressure table allocated to the grid block.

$P_{c_{TABLE-MAX}}$ = the maximum capillary pressure in the high salinity water wet water capillary pressure table allocated to the grid block (that is at the connate water saturation).

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.163 LWSOGCR – END-POINT SCALING GRID CELL SOGCR (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWSOGCR defines the critical oil saturation with respect to gas ("SOGCR"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil saturation in the low salinity water wet oil-gas relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.164 LWSOWCR – END-POINT SCALING GRID CELL SOWCR (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWSOWCR defines the critical oil saturation with respect to water ("SOWCR"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the oil saturation in the low salinity water wet water-oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.165 LWSWCR – END-POINT SCALING GRID CELL SWCR (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWSWCR defines the critical water saturation ("SWCR"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water saturation in the low salinity water wet water-oil relative permeability saturation tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.166 LWSWL – END-POINT SCALING GRID CELL SWL (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWSWL defines the connate water saturation ("SWL"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water saturation in the low salinity water wet water-oil relative permeability saturation tables, as well as the associated capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.167 LWSWLPC – END-POINT SCALING GRID CELL SWLPC (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWSWLPC defines the capillary pressure connate water saturation ("SWLPC"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water saturation in the low salinity water wet water-oil capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

Note the keyword only applies the scaling to the capillary pressures tables, unlike the LWSWL keyword that applies the scaling to both the capillary pressure and relative permeability tables.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.168 LWSWU – END-POINT SCALING GRID CELL SWU (LOW SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

LWSWU defines the maximum water saturation("SWU"), for all the cells in the model via an array, for when the Low Salt and Surfactant Wettability options have been selected. The data is used to scale the water saturation in the low salinity water wet water-oil relative permeability saturation tables, as well as the associated capillary pressure tables. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Low Salt option should be activated by the LOWSALT keyword in the RUNSPEC section and the Surfactant Wettability option activated by the SURFACT or SURFACTW keywords, which are also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.169 MASSFLOW – DEFINE RIVER MASS FLOW VERSUS TIME TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The MASSFLOW keyword defines the upstream river mass flow versus time tables for rivers, for when the River option has been activated via the RIVRDIMS keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.170 MAXVALUE – SETS A MAXIMUM VALUE FOR AN ARRAY ELEMENT

The MAXVALUE keyword sets a maximum value for the specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the MAXVALUE keyword is being used.

See *MAXVALUE – Sets a Maximum Value for an Array Element* in the GRID section for a full description.

8.3.171 MESSAGE – OUTPUT USER MESSAGE

The MESSAGE keyword outputs a user message to the terminal, as well as to the print (*.PRT) and debug (*.DBG) files. Note this is different to the MESSAGES keyword, that defines OPM Flows message print limits and stop limits generated by the simulator.

See *MESSAGE – Output User Message* in the GLOBAL section for a full description.

8.3.172 MESSAGES – DEFINE MESSAGE PRINT LIMITS AND STOP LIMITS

The MESSAGES keyword defines the print and stops levels for various messages. The "print limits" set the maximum number of messages that will be printed, after which no more messages will be printed and the "stop limits" terminate the run when these limits are exceeded. There are six levels of message that increase in severity from informative all the way to programming errors, as outlined in Error: Reference source not found.

See *MESSAGES – Define Message Print Limits and Stop Limits* in the GLOBAL section for a full description.

8.3.173 MINVALUE – SET A MINIMUM VALUE FOR AN ARRAY ELEMENT

The MINVALUE keyword sets a minimum value for the specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the MINVALUE keyword is being used.

See *MINVALUE – Set a Minimum Value for an Array Element* in the GRID section for a full description.

8.3.174 MICPPARA – DEFINE MICROBIALLY INDUCED CALCITE PRECIPITATION PARAMETERS

Description

The MICPPARA keyword defines the model parameters for when the MICP model has been activated via the MICP keyword in the RUNSPEC section. In addition to the MICP keyword the water phase should be made active via the WATER keyword in the RUNSPEC section. See Landa-Marbán et al[202] and [203] for further information on the model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DENBIO	A real positive value that defines the density of the biofilm.			
		lb/rft^3 2.18	kg/rm^3 35.0	gm/rcc 0.035	Defined
2	DENCAL	A real positive value that sets the calcite density.			
		lb/rft^3 169.18	kg/rm^3 2710.0	gm/rcc 2.710	Defined
3	DETRAT	DETRAT is a real positive value that stipulates the biofilm detachment rate.			
		feet/cP 8.53 x 10^{-13}	m/cP 2.6 x 10^{-1}3	cm/cP 2.6 x 10^{-1}1	Defined
4	CRIPOR	CRIPOR is a real positive value that defines the critical porosity., the value of porosity that equates to the minimum permeability MINPER.			
		dimensionless	dimensionless	dimensionless	0.10
5	FITFAC	A real positive value that declares the exponent in the porosity-permeability relationship. $$K = k_o\left[\left(\frac{\phi-\phi_{crit}}{\phi_0-\phi_{crit}}\right)^{\alpha} + k_{min}\right]\frac{k_o}{k_o+k_{min}}$$ Where α is FITFAC in the above equation. See Landa-Marbán et al202 and [203] for details.			
		dimensionless	dimensionless	dimensionless	3.0
6	HVEOXY	HVEOXY is a real positive value that stipulates the half-velocity coefficient for oxygen.			Defined

[202] *Landa-Marbán, D., Tveit, S., Kumar, K., Gasda, S.E., 2021. Practical approaches to study microbially induced calcite precipitation at the eld scale. Int. J. Greenh. Gas Control 106, 103256. https://doi.org/10.1016/j.ijggc.2021.103256.*

[203] *Landa-Marbán, D., Kumar, K., Tveit, S., Gasda, S.E., 2021. Numerical studies of CO2 leakage remediation by micp-based plugging technology. In: Røkke, N.A. and Knuutila, H.K. (Eds) Short Papers from the 11th International Trondheim CCS conference, ISBN: 978-82-536-1714-5, 284-290.*

No.	Name	Description			Default
		Field	Metric	Laboratory	
		lb/rft^3 1.25 x 10^{-6}	kg/rm^3 2.0 x 10^{-5}	gm/rcc 2.0 x 10^{-8}	
7	HVEURE	A real positive value that defines the half-velocity coefficient for urea.			
		lb/rft^3 1.33	kg/rm^3 21.3	gm/rcc 0.213	Defined
8	MGRRAT	MGRRAT is a real positive value that sets the maximum specific growth rate.			
		1/days 3.6	1/days 3.6	1/hours 0.15	Defined
9	MOXCON	A real positive value that stipulates the maximum injected oxygen concentration.			
		lb/stb 2.5 x 10^{-3}	kg/sm^3 0.04	gm/scc 4.0 x 10^{-5}	Defined
10	MURCON	MURCON is a real positive value that defines the maximum injected urea concentration.			
		lb/stb 3.75	kg/sm^3 60.0	gm/scc 0.060	Defined
11	MURUTI	A real positive value that sets the maximum rate of urea utilization.			
		1/days 1391	1/days 1391	1/hours 57.96	Defined
12	MIARAT	MIARAT is a real positive value that declares the microbial attachment rate.			
		1/days 0.074	1/days 0.074	1/hours 0.003	Defined
13	MIDRAT	A real value that defines the microbial death rate.			
		1/days 0.028	1/days 0.0028	1/hours 0.001	Defined
14	MINPER	MINPER is a real positive value that defines the minimum permeability.			
		mD	mD	mD	1.013 x 10^{5}
15	OXCFAC	A real value that stipulates the oxygen consumption factor.			
		dimensionless	dimensionless	dimensionless	0.5
16	TOLCLO	TOLCLO is a real positive value that defines the tolerance to be used in the calculation of the clogging termination criteria.			
		dimensionless	dimensionless	dimensionless	1.0 x 10^{-4}

No.	Name	Description			Default
		Field	Metric	Laboratory	
17	YGRCOE	A real value that sets the yield growth coefficient.			
		dimensionless	dimensionless	dimensionless	0.5
Notes: 1) The keyword is terminated by a "/".					

Table 8.87: MICPPARA Keyword Description

Note

1) This is an OPM Flow specific keyword.
2) Unlike some of the other PROPS keywords that allocate fluid and rock properties to different regions of the model using the PVTNUM and SATNUM keywords in the REGIONS section, the MICPPARA keyword parameters are applied to all the cells in the model.

Example

```
--
--       DEFINE MICROBIALLY INDUCED CALCITE PRECIPITATION PARAMETERS
--
--       DEN     DEN     DET     CRI     FIT     HVE     HVE     MGR
--       BIOF    CAL     RAT     POR     FAC     OXY     URE     RAT
--       ------  ------  ------  ------  ------  ------  ------  ------  ------
--       MOX     MUR     MUR     MIA     MID     MIN     OXC     TOL     YGR
--       CON     CON     UTI     RAT     RAT     PER     FAC     CLO     COE
--       ------  ------  ------  ------  ------  ------  ------  ------  ------
MICPPARA
         35.     2710.   2.6E-13 0.1     3.      2E-5    21.3    3.6
         0.04    60.     1391.   0.074   0.028  1.013E-5 0.5     1E-4    0.5    /
```

The above example defines the 17 model parameters for the MICP model in the metric system.

8.3.175 MISC – DEFINE SOLVENT MISCIBILITY-IMMISCIBILITY TRANSFORM FUNCTIONS

Description

MISC defines the transformation between the miscible and immiscible relative permeability models, for when the MISCIBLE and SOLVENT keywords in the RUNSPEC section have been activated. The keyword can only be used with the MISCIBLE option and for when the oil, water, gas and solvent phases are active in the model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SSOL	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the solvent fraction with respect to the solvent and gas saturation, and is defined by: $\frac{S_s}{(S_g + S_s)}$ Where Sg is the gas saturation and Ss is the solvent saturation. Note that the first entry in the columnar vector should be zero and the last entry should be one to fully define the solvent fraction range.			
		dimensionless	dimensionless	dimensionless	None
2	MISC	A columnar vector of real equal or increasing down the column values that are greater than or equal to zero and less then one, that define the corresponding miscibility for the corresponding solvent fraction SSOL. The first entry in the columnar vector should be zero and the last entry should be one to fully define the miscible-immiscible relationship.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTMISC tables as declared on the MISCIBLE keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSMISC rows as declared on the MISCIBLE keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.88: MISC Keyword Description

Example

```
--
--       SOLVENT MISCIBILITY-IMMISCIBLITY TRANSFORM TABLE
--
MISC
--       SSOL       MISC
--       FRAC       FRAC
--       -------    --------
          0.0000     0.0000
          0.2000     0.2500
          0.5000     0.7500
          1.0000     1.0000                                  / TABLE NO. 01

--       SSOL       MISC
--       FRAC       FRAC
--       -------    --------
          0.0000     0.0000
          0.3000     0.2500
          0.6000     1.0000
          1.0000     1.0000                                  / TABLE NO. 02
```

The above example defines two solvent miscible-immiscible transform tables assuming NTMISC equals two and NSMISC is greater than or equal to four on the MISCIBLE keyword in the RUNSPEC section.

8.3.176 MLANG – DEFINE LANGMUIR MAXIMUM GAS CONCENTRATION FOR ALL GRID CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, MLANG, defines the coal bed methane Langmuir Adsorption[204] maximum gas concentration for each grid cell used to scale the Langmuir isotherm table allocated to the cell, for when the Coal Bed Methane option has been activated via the COAL keyword in the RUNSPEC section. See the LANGMUIR keyword in the PROPS section for specifying the Langmuir tables for the model.

Note that if he Dual Porosity model has been activated by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section, then MLANG applies to only the matrix grid block.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[204] *Langmuir, Irving (June 1918). "The Adsorption of Gases on Plane Surface of Glass, Mica and Platinum". The Research Laboratory of the General Electric Company. 40 (9): 1361–1402. doi:10.1021/ja02242a004*

8.3.177 MLANGSLV – DEFINE LANGMUIR MAXIMUM SOLVENT CONCENTRATION FOR ALL GRID CELLS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, MLANGSLV, defines the coal bed methane Langmuir Adsorption[205] maximum solvent concentration for each grid cell used to scale the Langmuir isotherm solvent table allocated to the cell, for when the Coal Bed Methane option has been activated via the COAL keyword in the RUNSPEC section. In addition, the Solvent phase must have been declared by the SOLVENT keyword in the RUNSPEC section. See the COALNUM keyword in the GRID section for allocating the Langmuir solvent tables to the grid blocks, and also the LANGMUIR keyword in the PROPS section for defining the Langmuir Adsorption Isotherm tables. Keywords COALADS and COALPP, also in the PROPS section, are used to specify the relative adsorption data in runs containing the solvent phase.

Note that if he Dual Porosity model has been activated by either the DUALPORO or the DUALPERM keywords in the RUNSPEC section, then MLANGSLV applies to only the matrix grid block.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[205] *Langmuir, Irving (June 1918). "The Adsorption of Gases on Plane Surface of Glass, Mica and Platinum". The Research Laboratory of the General Electric Company. 40 (9): 1361–1402. doi:10.1021/ja02242a004*

8.3.178 MSFN – MISCIBLE NORMALIZED RELATIVE PERMEABILITY TABLES

Description

The MSFN keyword defines the miscible normalized relative permeability tables for when the MISCIBLE and or SOLVENT options have been activated in the RUNSPEC section using the respective keyword. The MISCIBLE keyword invokes a three component formulation (oil, water and solvent gas or an oil, water and solvent oil). Whereas the SOLVENT keyword results in a four component model (oil, water and gas plus a solvent). This keyword should only be used if the MISCIBLE and or SOLVENT options have been activated.

No.	Name	Description	Default
1	SGAS	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the gas plus solvent saturation.	None
2	KRSG	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the gas plus solvent relative permeability multiplier.	None
3	KRO	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the oil relative permeability multiplier.	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by "/" and there is no "/" terminator for the keyword.

Table 8.89: MSFN Keyword Description

Example

```
--
--        MISCIBLE NORMALIZED RELATIVE PERMEABILITY TABLES
--
MSFN
--        SGAS        KRSG          KRO
--        FRAC
--        --------   --------      --------
           0.0000     0.0000        1.0000
           1.0000     1.0000        0.0000                    / TABLE NO. 01

--        SGAS        KRSG          KRO
--        FRAC
--        --------   --------      --------
           0.0000     0.0000        1.0000
           0.2000     0.2000        0.8000
           0.4000     0.3000        0.7000
           0.6000     0.4000        0.6000
           0.8000     0.5000        0.4000
           1.0000     1.0000        0.0000                    / TABLE NO. 02
```

The above example defines two MSN tables for use the MISCIBLE and SOLVENT options.

8.3.179 MULTIPLY – MULTIPLY A SPECIFIED ARRAY BY A CONSTANT

The MULTIPLY keyword multiplies a specified array or part of an array by a constant. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

See *MULTIPLY – Multiply a Specified Array by a Constant* in the GRID section for a full description.

8.3.180 MULTIREG – MULTIPLY AN ARRAY BY A CONSTANT BASED ON A REGION NUMBER

The MULTIREG keyword multiplies an array or part of an array by a constant for cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTIREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the MULTIREG keyword is being used.

See *MULTIREG – Multiply an Array by a Constant based on a Region Number* in the GRID section for a full description.

8.3.181 NCOMPS – CONFIRM NUMBER OF COMPOSITIONAL COMPONENTS

Description

This keyword confirms the maximum number of compositional components in the model, as such it should have the same number of components as that declared via the COMPS keyword in the RUNSPEC section. The keyword should only be used if the CO2STORE keyword and either the GASWAT or the GAS and WATER keywords in the RUNSPEC section, have also be activated for the gas-water two component model.

Note

This is an OPM Flow keyword used with OPM Flow's CO2STORE and GASWAT keywords in the RUNSPEC section, and should not be confused with the more general version of the NCOMPS keyword used in the commercial compositional simulator.

Secondly, although OPM Flow parses the keyword, the simulator currently ignores the data for this keyword.

No.	Name	Description	Default
1	NCOMPS	A positive integer defining the maximum number of compositional components in the model. Secondly the number of components must be the same as that enter via the COMPS keyword in the RUNSPEC section. Only the default value of two is currently supported by OPM Flow.	2
Notes: 1) The keyword is terminated by a "/".			

Table 8.90: NCOMPS Keyword Description

Example

The following example defines how to confirm a two component formulation to be used with the CO2STORE and GASWAT options.

```
--
--        CONFIRM NUMBER OF COMPOSITIONAL COMPONENTS (OPM FLOW KEYWORD)
--
NCOMPS
         2                                                                  /
```

8.3.182 NOECHO – DEACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns off echoing of all the input files to the print file. Note by default echoing of the inputs files is active. but can subsequently be switched off by the NOECHO activation keyword.

See *NOECHO – Deactivate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

8.3.183 NOWARN – DEACTIVATE WARNING MESSAGES

Turns off warning messages to be printed to the print file; note that this keyword is deactivated by default and can subsequently be switched off by the WARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN.

See *NOWARN – Deactivate Warning Messages* in the GLOBAL section for a full description.

8.3.184 NOWARNEP – DEACTIVATE END-POINT SCALING WARNING MESSAGES

Description

The NOWARNEP keyword deactivates the writing out of warning messages associated with checking the consistency of saturation table end-points; however error messages are still reported by the simulator.

Hence, OPM Flow ignores this keyword but it is documented here for completeness.

There is no data required for this keyword and there is no terminating "/" for this keyword.

Example

```
--
--        DEACTIVATE END-POINT SCALING WARNING MESSAGES
--
NOWARNEP
```

The above example switches off the writing out of warning messages associated with checking the consistency of saturation table end-points;

8.3.185 OILDENT – DEFINE OIL DENSITY TEMPERATURE COEFFICIENTS

Description

OILDENT defines the oil density as a function of temperature coefficients for when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC. Note this is an OPM Flow keyword used with OPM Flow's black-oil thermal model that is not available in the commercial simulator's black-oil thermal formulation.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	TEMP is a real positive value greater than zero that defines the absolute reference temperature used with TEXP1 and TEXP2 to estimate the change in oil density with respect to temperature.			
		°R 527.67	K 293.15	K 293.15	Defined
2	TEXP1	TEXP1 is a real positive value greater than zero that defines the oil thermal expansion coefficient of the first order.			
		1/°R 1.67×10^{-4}	1/K 3.0×10^{-4}	1/K 3.0×10^{-4}	Defined
3	TEXP2	TEXP2 is a real positive value greater than zero that defines the oil thermal expansion coefficient of the second order.			
		1/°R2 9.26×10^{-7}	1/K2 3.0×10^{-6}	1/K2 3.0×10^{-6}	Defined

Notes:

1) The keyword is followed by NTPVT records as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each data set is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.91: OILDENT Keyword Description

The oil density at a given pressure and temperature is calculated from its value at surface conditions and the oil shrinkage factor (the reciprocal of the oil formation volume factor) as shown in the following equation:

$$\rho_o(p,T) = \rho_o(p_s,T_s)\, b_o(p,T) \tag{8.68}$$

Where the temperature dependence of the oil shrinkage factor relative to its value at the reference temperature is calculated as shown in the following equation:

$$b_o(p,T)=\frac{b_o(p,T_{ref})}{1+c_1(T-T_{ref})+c_2(T-T_{ref})^2} \tag{8.69}$$

Where:

ρ_o = oil density
b_o = oil shrinkage factor
p = pressure
T = temperature
c_1, c_2 = thermal expansion coefficients to first and second order
s = subscript indicating surface conditions
ref = subscript indicating reference conditions

Example

The following example shows the OILDENT keyword using the default values, for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to two.

```
--
--       OIL DENSITY TEMPERATURE COEFFICIENTS (OPM FLOW THERMAL KEYWORD)
--
--       OIL         DENSITY   DENSITY
--       TEMP        COEFF1    COEFF2
--       --------    -------   -------
OILDENT
         1*          1*        1*                          / TABLE NO. 01
         1*          1*        1*                          / TABLE NO. 02
```

There is no terminating "/" for this keyword.

8.3.186 OILJT – DEFINE OIL JOULE-THOMSON COEFFICIENT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

OILJT activates the oil Joule-Thomson effect[206] in temperature calculations, and defines the oil Joule-Thomson Coefficient ("JTC") at a given reference pressure, for when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC.

Note

This is an OPM Flow keyword used with OPM Flow's black-oil thermal model, that is not available in the commercial simulator's black-oil thermal formulation.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model, and does not include the Joule-Thomson effect in temperature calculations.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A real positive value that defines the reference pressure for the corresponding Joule-Thomson Coefficient, OILJTC.			
		psia	barsa	atma	None
2	OILJTC	OILJTC is a real positive or negative value that defines the oil phase Joule-Thomson Coefficient. If the value is defaulted (1*) or set to 0, then OILJTC is internally calculated using the thermal oil density data on the OILDENT keyword in the PROPS section. If a non-zero value is specified, then the OILJTC is assumed to be constant and equal to that value.			
		oF/psia	°C/barsa	°C/atma	0

Notes:

1) The keyword is followed by NTPVT records as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each data set is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.92: OILJT Keyword Description

The Joule–Thomson effect is when a real gas, as oppose to an ideal gas, expands, resulting in the temperature of the gas dropping[207]. For liquids the effect is the opposite, that is the internal energy is transferred to kinetic energy with a corresponding increase in temperature as velocity increases.

Thermodynamically, the Joule–Thomson coefficient is defined as the isenthalpic[208] change in temperature in a fluid caused by a unitary pressure drop, as shown in the following equation:

[206] *The Joule–Thomson coefficient is defined as the change in temperature with respect to an increase in pressure at constant enthalpy.*

[207] *Natural Gas Engineering (McGraw-Hill chemical engineering series), Donald L. Katz, Robert I Lee, McGraw-Hill Education, 1990 (ISBN 0071007776, 9780071007771).*

$$\eta = \left(\frac{\partial T}{\partial P}\right) \tag{8.70}$$

Which can also express as[209]:

$$\eta = (T\alpha - 1)\frac{1}{(\rho C_p)} - \left(\frac{g}{C_p}\frac{dp}{dz}\right)^{-1} \tag{8.71}$$

Setting the gravity term, g, to zero we have:

$$\eta = (T\alpha - 1)\frac{1}{(\rho C_b)} \tag{8.72}$$

Where:

η	=	Joule–Thomson coefficient (oC/Pa),
α	=	thermal expansivity at constant pressure (1/oC),
C_p	=	specific heat at constant pressure (J/kg oC),
g	=	gravitational acceleration (m/s2)
P	=	pressure (Pa),
T	=	temperature (oC), and
z	=	height (m).

Example

The following example shows the OILJT keyword for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section, and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set equal to two.

```
--
--       OIL JOULE-THOMSON COEFFICIENT (OPM FLOW EXTENSION KEYWORD)
--
--       REF         OIL
--       PRESS       JTC
--       --------    -------
OILJT
         20.0        1*                  / TABLE NO. 01
         20.0        -0.20               / TABLE NO. 02
```

Here the first entry is defaulted, and the simulator will therefore calculate the oil JTC internally using the data on the OILDENT keyword in the PROPS section.

There is no terminating "/" for this keyword.

[208] *An isenthalpic process or isoenthalpic process, is a process that proceeds without any change in enthalpy, H; or specific enthalpy, h.*

[209] *Pippard, A.B.: Elements of Classical Thermodynamics: For Advanced Students of Physics. Cambridge University Press, Cambridge, UK (1957)*

8.3.187 OILVISCT – DEFINE OIL VISCOSITY VERSUS TEMPERATURE FUNCTIONS

Description

OILVISCT defines the oil viscosity as a function of temperature for when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. The reference pressure and solution gas-oil ratio of the oil for this table is given by the VISCREF keyword in the PROPS section. Note this is an OPM Flow keyword used with OPM Flow's black-oil thermal model that is not available in the commercial simulator's black-oil thermal formulation.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	A columnar vector of real monotonically increasing down the column values that defines the temperature values.			
		°F	°C	°C	None
2	VIS	A columnar vector of real increasing down the column values that defines the oil viscosity for the corresponding temperature values (TEMP). VIS should be given at the reference pressure and solution gas-oil ratio as defined by PRESS and RS variables on the VISCREF keyword.			
		cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.93: OILVISCT Keyword Description

There is no terminating "/" for this keyword.

Example

The following example shows the OILVISCT keyword for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set equal to one.

```
--
--       OIL VISCOSITY VERSUS TEMPERATURE TABLES (OPM FLOW EXTENSION KEYWORD)
--
--       OIL         OIL
--       TEMP        VISC
--       --------    -------
OILVISCT
           100.0     0.600
           110.0     0.650
           120.0     0.680
           150.0     0.720
           165.0     0.725                                  / TABLE NO. 01
```

8.3.188 OPERATE – DEFINE MATHEMATICAL OPERATIONS ON ARRAYS

This keyword, OPERATE, defines mathematical operations on property arrays (NTG, PORO etc.) and optionally using another property array as input to the function. The keyword allows for various mathematical functions and their associated variables to be defined and applied to the selected array data. Input constants can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

See *OPERATE – Define Mathematical Operations on Arrays* in the GRID section for a full description.

8.3.189 OPERATER – DEFINE MATHEMATICAL OPERATIONS ON ARRAYS BY REGION

This keyword defines the mathematical operations on arrays for specific regions in the commercial simulator and is currently not supported by OPM Flow. However, similar functionality is provided by the ADD and MULTIPLY keywords.

See *OPERATER – Define Mathematical Operations on Arrays by Region* in the GRID section for a full description.

8.3.190 OVERBURD – DEFINE ROCK OVERBURDEN PRESSURE VERSUS DEPTH TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The OVERBURD keyword defines the overburden pressures versus depth relationship to be applied for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section.

The rock compaction pore volume and transmissibility multipliers, entered via the ROCKTAB, ROCK2D and ROCK2DTR keywords, are applied to the pore pressure, unless the OVERBURD keyword is included in the input deck. When the OVERBURD keyword is present the multipliers are applied to the effective pore volume pressure, that is $P_{(effective)} = P_{(Pressure)} - P_{(overburden)}$. If the keyword is not present in the input deck then the overburden pressure is set to zero.

This keyword should only be used if compaction option has been enabled.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DEPTH	A columnar vector of real monotonically increasing down the column values that defines the depth for corresponding overburden pressure parameter PRESS.			
		feet	m	cm	None
2	PRESS	A columnar vector of real monotonically increasing down the column values that defines the corresponding overburden pressure for the given DEPTH.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTROCC tables as declared on the ROCKCOMP keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.94: OVERBURD Keyword Description

See also the ROCKTAB, ROCK2D, ROCK2DTR, and ROCKWNOD keywords in the PROPS section.

Examples

The example below defines three overburden tables, assuming NTROCC is equal to three on the ROCKCOMP keyword and NPPVT is greater than or equal to four on the TABDIMS keyword.

```
--
--        OVERBURDEN PRESSURE VERSUS DEPTH TABLES
--
OVERBURD
--        DEPTH     OVERBURDEN
--        FEET      PRESSURE
--        ------    ----------
          1000.0     300.000
          2000.0     600.000
          3000.0     900.000
          4000.0    1200.000                                  / TABLE N0. 01
--        DEPTH     OVERBURDEN
--        FEET      PRESSURE
--        ------    ----------
          1000.0     200.000
          2000.0     400.000
          3000.0     800.000
          4000.0    1000.000                                  / TABLE N0. 02
--        DEPTH     OVERBURDEN
--        FEET      PRESSURE
--        ------    ----------
          1000.0     400.000
          2000.0     800.000
          3000.0    1100.000
          4000.0    1500.000                                  / TABLE N0. 03
```

Note that there must be exactly NTROCC tables entered for this keyword, otherwise an error will occur.

```
--
--        ROCK COMPACTION TABLES
--
ROCKTAB
--        PRESS     PORV      TX(YZ)
--                  MULT      MULT
--        ------    ------    ------
          1000.0    0.9600    0.9650
          1500.0    0.9800    0.9850
          3000.0    0.9900    0.9950
          4500.0    1.0000    1.0000
          4750.0    1.0100    1.0100                          / TABLE NO. 01
--        PRESS     PORV      TX(YZ)
--                  MULT      MULT
--        ------    ------    ------
          1000.0    0.9600    0.9650
          1500.0    0.9800    0.9850
          3000.0    0.9900    0.9950
          4500.0    1.0000    1.0000
          4750.0    1.0100    1.0100                          / TABLE NO. 02
--        PRESS     PORV      TX(YZ)
--                  MULT      MULT
--        ------    ------    ------
          1000.0    0.9600    0.9650
          2000.0    0.9800    0.9850
          3000.0    0.9900    0.9950
          4000.0    1.0100    1.0100                          / TABLE NO. 03
```

Here ROCKTAB tables one and two are identical.

8.3.191 PCG – END-POINT SCALING OF GRID CELL MAXIMUM GAS CAPILLARY PRESSURE (DRAINAGE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PCG defines the maximum drainage gas-oil capillary pressure values for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The keyword can be used with all grid types.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped. See also the IPCG keyword for the equivalent imbibition functionality.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PCG	PCG is an array of positive real numbers assigning the maximum drainage gas-oil capillary pressure values for each cell in the model. Repeat counts may be used, for example 30*100.0.			
		psia	bars	atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) If the HYSTER on the SATOPTS keyword in the RUNSPEC section has been activated to invoke hysteresis then PCG scales the drainage curve and IPCG scales the imbibition curve.

3) The keyword is terminated by a "/".

Table 8.95: PCG Keyword Description

The capillary pressure for a grid block is scaled by:

$$P_c = P_{c_{TABLE}} \left(\frac{PCG}{P_{c_{TABLE-MAX}}} \right) \quad (8.73)$$

Where:

P_c = the resulting drainage gas-oil capillary pressure for a grid cell.
PCG = the maximum capillary pressure from the PCG array for a given cell.
$P_{c_{TABLE}}$ = the capillary pressure in the drainage capillary pressure table allocated to the grid block.
$P_{c_{TABLE-MAX}}$ = the maximum capillary pressure in the drainage capillary pressure table allocated to the grid block at $S_g = 1 - S_{wco}$.

Example

```
--
--       DEFINE GRID BLOCK PCG DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PCG
         100*50.0  100*75.0  100*125.0                                          /
```

The above example defines the PCW for 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.192 PCG32D – GAS-OIL CAPILLARY PRESSURE VERSUS OIL AND WATER SATURATION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, PCG32D, enables the gas-oil capillary pressure data to be entered as a function of both oil and water saturations. The keyword should be used in conjunction with the SGF32D keyword in the PROPS section. See also the PCW32D keyword in the PROPS section that provides similar functionality for the water-oil capillary pressure data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.193 PCW – END-POINT SCALING OF GRID CELL WATER CAPILLARY PRESSURE (DRAINAGE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PCW defines the maximum drainage water-oil or water-gas capillary pressure values for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. The keyword can be used with all grid types.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PCW	PCW is an array of positive real numbers assigning the maximum drainage water capillary pressure values for each cell in the model. Repeat counts may be used, for example 30*100.0.			
		psia	bars	atm	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) If the HYSTER on the SATOPTS keyword in the RUNSPEC section has been activated to invoke hysteresis then PCW scales the drainage curve and IPCW scales the imbibition curve.

3) The keyword is terminated by a "/".

Table 8.96: PCW Keyword Description

See also the IPCW keyword for the equivalent imbibition functionality.

The capillary pressure for a grid block is scaled by:

$$P_c = P_{c_{TABLE}} \left(\frac{PCW}{P_{c_{TABLE-MAX}}} \right) \quad (8.74)$$

Where:

P_c = the resulting drainage water capillary pressure for a grid cell.

PCW = the maximum capillary pressure from the PCW array for a given cell.

$P_{c_{TABLE}}$ = the capillary pressure in the drainage capillary pressure table allocated to the grid block.

$P_{c_{TABLE-MAX}}$ = the maximum capillary pressure in the drainage capillary pressure table allocated to the grid block (that is at the connate water saturation).

Example

```
--
--        DEFINE GRID BLOCK PCW DATA FOR ALL CELLS (BASED ON NX x NY x NZ = 300)
--
PCW
          100*50.0  100*75.0  100*125.0                                          /
```

The above example defines the PCW for 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.194 PCW32D – WATER-OIL CAPILLARY PRESSURE VERSUS OIL AND GAS SATURATION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, PCW32D, enables the water-oil capillary pressure data to be entered as a function of both oil and gas saturations. The keyword should be used in conjunction with the SWF32D keyword in the PROPS section. See also the PCG32D keyword in the PROPS section that provides similar functionality for the gas-oil capillary pressure data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.195 PECOEFS – DEFINE PETRO-ELASTIC MODEL COEFFICIENTS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PECOEFS keyword defines the Petro-Elastic model coefficients.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.196 PEGTAB – PETRO-ELASTIC PRESSURE SHEAR MODULUS TABLE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PEGTAB series of keywords define a series of coefficients of a polynomial function used in the calculation of the shear modulus in the petro-elastic model. The series of keywords consist of: PEGTAB0 PEGTAB1, PEGTAB2, PEGTAB3, PEGTAB4, PEGTAB5, PEGTAB6, and PEGTAB7.

This series of keywords are ignored by OPM Flow and have no effect on the simulation.

8.3.197 PEKTAB – PETRO-ELASTIC PRESSURE BULK MODULUS TABLE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PEKTAB series of keywords define a series of coefficients of a polynomial function used in the calculation of the bulk modulus in the petro-elastic model. The series of keywords consist of: PEKTAB0 PEKTAB1, PEKTAB2, PEKTAB3, PEKTAB4, PEKTAB5, PEKTAB6, and PEKTAB7.

This series of keywords are ignored by OPM Flow and have no effect on the simulation.

8.3.198 PERMFACT – PERMEABILITY MULTIPLICATION FACTOR AS A FUNCTION OF POROSITY CHANGE

Description

PERMFACT defines the permeability multiplication factor due to a change in porosity. Currently the keyword is used in conjunction with OPM Flow's Salt Precipitation model, in which the pore space is reduced due to salt precipitating in the pore space, causing a reduction in porosity and an associated reduction in permeability.

Note

This is an OPM Flow specific keyword for the simulator's Salt Precipitation model that is activated by the BRINE and PRECSALT keywords and declaring that vaporized water is present in the run via the VAPWAT keyword. All three keywords are in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	POROFAC	A real monotonically increasing positive columnar vector that defines the porosity ($\frac{\phi}{\phi_0}$) factor for the corresponding PERMFAC vector. In the simulator's Salt Precipitation model, the maximum value of Φ is Φ0, implying a maximum value of one for POROFAC.			
		dimensionless	dimensionless	dimensionless	None
2	PERMFAC	A real positive monotonically increasing columnar vector that defines the permeability (k) multiplier associated with POROFAC and used to scale a grid block's permeability due to the reduction in pore volume caused by salt precipitation. Where: $PERMFAC = m(\phi)$ $with\ k = m(\phi)k_0$			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) There must be same number of entries for each column.
4) Each table is terminated by a single "/" and the keyword is terminated by a "/".

Table 8.97: PERMFACT Keyword Description

The porosity reduction is a function of the volume fraction of salt (ss) precipitated out of the vaporized water phase, that is:

$$\phi = (1 - s_s)\,\phi_o \tag{8.75}$$

The porosity and associated permeability factor data can be calculated using a permeability-porosity

relationship, for example:

$$\frac{k}{k_o} = \left(\frac{\phi - \phi_c}{\phi_o - \phi_c} \right)^{\gamma} \tag{8.76}$$

Where:

k_o and ϕ_o	=	the initial permeability and porosity,
k and ϕ	=	the actual permeability and porosity that changes due to precipitation or dissolution of the salt,
ϕ_c	=	the residual porosity at which permeability is zero, and
γ	=	a positive exponent.

See also Kozeny-Carment (extended)[210], [211] and [212] and Verma-Pruess[213] for additional functional forms that can be used to derive the tabulated data that can be entered via the PERMFACT keyword.

Example

The example below defines two PERMFACT tables assuming NTPVT equals two and NPPVT is greater than or equal to five on the TABDIMS keyword in the RUNSPEC section.

```
--
--       PERMEABILITY FACTOR REDUCTION DUE TO SALT PRECIPITATION
--       (OPM FLOW KEYWORD)
--
PERMFACT
--       PORO       PERM
--       FACTOR     FACTOR
--       -------    --------
         0.00        0.0000
         0.25        0.0625
         0.50        0.2500
         0.75        0.5625
         1.00        1.0000                    / TABLE NO. 01
--       -------    --------
         0.00        0.0000
         0.25        0.0625
         0.50        0.2500
         0.75        0.5625
         1.00        1.0000                    / TABLE NO. 02
/
```

Both tables use equation (8.76) with Φc equal to zero and ɣ equal to 2.0. Note that PERMFACT changes the permeability in all three dimensions, that is the PERMX, PERMY and PERMZ arrays are all modified.

Finally, notice that the terminating "/" for this keyword.

8.3.199 PLMIXPAR – DEFINE THE POLYMER TODD-LONGSTAFF MIXING PARAMETERS

Description

The PLMIXPAR keyword defines the Todd-Longstaff[214] mixing parameters for when the polymer option has been activated by the POLYMER keyword in the RUNSPEC section. This keyword must be present in the input deck if the POLYMER keyword has been activated.

Note that this keyword is used only for the polymer option, if the MISCIBLE keyword in the RUNSPEC section has been invoked then in addition the TLMIXPAR keyword is also required to define the Todd-Longstaff mixing parameters for the MISCIBLE option.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PLMVIS	A real positive value that is greater than or equal to zero and less than or equal to one, that defines the viscosity Todd-Longstaff mixing parameter for each polymer region.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NPLMIX tables as declared on the REGDIMS keyword in the RUNSPEC section, for each rock region. There should be only one row per table.

2) Each entry is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.98: PLMIXPAR Keyword Description

Example

```
--
--       POLYMER TODD-LONGSTAFF MIXING PARAMETERS
--
PLMIXPAR
--       PLM
--       VISCOS
--       -------
         0.3500                                    / TABLE NO. 01
         0.2500                                    / TABLE NO. 02
         0.6500                                    / TABLE NO. 03
```

The above example defines three polymer Todd-Longstaff mixing parameter data sets, based on the NPLMIX variable on the REGDIMS keyword in the RUNSPEC section being equal to three.

[214] *Todd, M. and Longstaff, W. "The Development, Testing and Application of a Numerical Simulator for Predicting Miscible Flood Performance," paper SPE 3484, Journal of Canadian Petroleum Technology (1972) 24, No. 7, 874-882.*

8.3.200 PLYADS - DEFINE POLYMER ROCK ADSORPTION TABLES

Description

The PLYADS keyword defines the rock polymer adsorption tables for when the polymer option has been activated by the POLYMER keyword in the RUNSPEC section. Alternatively, the functions can be entered via the PLYADSS keyword in the PROPS section for when salt sensitivity is to be considered.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	POLCON	A columnar vector of real monotonically increasing down the column values that defines the polymer concentration in the solution surrounding the rock. The first entry should be zero to define a no polymer concentration.			
		lb/stb	kg/sm^3	gm/scc	None
2	POLRATIO	A columnar vector of real increasing down the column values that defines the mass of adsorbed polymer per unit mass of rock. The first entry should be zero to define a zero ratio of polymer concentration.			
		lb/lb	kg/kg	gm/gm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.99: PLYADS Keyword Description

See also the PLYADSS keyword in the PROPS section to also define rock polymer adsorption tables when the polymer concentration is a function of salinity.

Example

```
--
--       POLYMER ROCK ADSORPTION TABLE
--
PLYADS
--       POLYMER    POLYMER
--       POLCON     POLRATIO
--       -------    --------
             0.0     0.00000
             2.0     0.00003
             4.0     0.00005
             6.0     0.00007
             8.0     0.00009
            10.0     0.00011
            12.0     0.00012
            14.0     0.00015                              / TABLE NO. 01
--       POLYMER    POLYMER
--       POLCON     POLRATIO
--       -------    --------
             0.0     0.00000
             3.0     0.00004
             5.0     0.00006
             7.0     0.00008
             8.0     0.00009
            10.0     0.00011                              / TABLE NO. 02
```

The above example defines two polymer rock adsorption tables assuming NTSFUN equals two and NSSFUN is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section.

There is no terminating "/" for this keyword.

8.3.201 PLYADSS - DEFINE POLYMER ROCK ADSORPTION WITH SALT DEPENDENCE TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PLYADSS keyword defines the rock polymer adsorption tables for when the polymer and the salt options has been activated by the POLYMER and BRINE keywords in the RUNSPEC section.

Note that the BRINE option is not currently supported by OPM Flow; however, the polymer rock adsorption functions without salt dependence may be entered via the PLYADS keyword in the PROPS section, for when salt sensitivity is not to be considered.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	POLCON	A columnar vector of real monotonically increasing down the column values that defines the polymer concentration in the solution surrounding the rock. The first entry should be zero to define a no polymer and no salt concentration data set. POLCON should only be given for the first entry of the POLCON/POLRATIO set and skipped until another POLCON/POLRATIO table is entered.			
		lb/stb	kg/sm^3	gm/scc	None
2	POLRATIO	A columnar vector of real increasing down the column values that defines the mass of adsorbed polymer per unit mass of rock of the saturated concentration of polymer adsorbed by the rock for a given POLCON and the salt concentration given by SALTCON on the ADSALNOD keyword in the PROPS section. The first table data set entry should be zero to define a no polymer and no salt concentration data set. Subsequent POLRATIO values define the POLCON/POLRATIO combinations for a given salt concentration as listed (and in the same order) by the SALTCON variable on the ADSALNOD keyword in the PROPS section. Each POLCON/POLRATIO/SALT data sets should be terminated by a "/"			
		lb/lb	kg/kg	gm/gm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.100: PLYADSS Keyword Description

See also the PLYADS keyword in the PROPS section to also define rock polymer adsorption tables when the polymer concentration is not a function of salinity.

Example

```
--
--       SETS SALT CONCENTRATION FOR POLYMER SOLUTION ADSORPTION
--       VIA SATNUM ARRAY ALLOCATION
--
--       SALT
--
ADSALNOD
         1.0
         5.0
         10.5
         25.0      / SATNUM TABLE NO. 01
--
--       POLYMER ROCK ADSORPTION WITH SALT DEPENDENCY TABLE
--
PLYADSS
--       POLYMER    POLYMER
--       POLCON     POLRATIO
--       -------    --------
             0.0     0.00000
                     0.00000
                     0.00000
                     0.00000                              / TABLE NO. 01
--       POLYMER    POLYMER
--       POLCON     POLRATIO
--       -------    --------
             1.0     0.00002
                     0.00003
                     0.00004
                     0.00005                              / TABLE NO. 02

--       POLYMER    POLYMER
--       POLCON     POLRATIO
--       -------    --------
             2.0     0.00003
                     0.00004
                     0.00005
                     0.00006                              / TABLE NO. 03
--       POLYMER    POLYMER
--       POLCON     POLRATIO
--       -------    --------
             3.0     0.00004
                     0.00005
                     0.00006
                     0.00007                              / TABLE NO. 04
```

The above example defines four polymer rock adsorption tables for four salt concentration on the ADSALNOD keyword, assuming NTSFUN equals one and NSSFUN is greater than or equal to four on the TABDIMS keyword in the RUNSPEC section.

There is no terminating "/" for this keyword.

8.3.202 PLYATEMP – DEFINE POLYMER ADSORPTION TABLE TEMPERATURE

Description

This keyword defines the polymer adsorption temperature for subsequent polymer adsorption tables entered via the PLYADS and PLYADSS keywords in the PROPS section. The Polymer option must have been activated by the POLYMER keyword in the RUNSPEC section and the Thermal option invoked by the THERMAL keyword, also in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PLYATEMP	Single real positive value that defines polymer adsorption temperature for subsequent polymer adsorption tables.			
		°F	°C	°C	None
Notes: 1) The keyword is terminated by a "/".					

Table 8.101: PLYATEMP Keyword Description

Example

The example shows how to enter the polymer adsorption data using the PLYADS keyword for two different temperatures.

```
--
--        RESERVOIR
--        TEMPERATURE
--        -----------
PLYATEMP
          60.0                                          / TEMPERATURE
--
--        POLYMER ROCK ADSORPTION TABLE
--
PLYADS
--        POLYMER    POLYMER
--        POLCON     POLRATIO
--        -------    --------
              0.0     0.00000
              2.0     0.00003
              4.0     0.00005
              6.0     0.00007
              8.0     0.00009
             10.0     0.00011
             12.0     0.00012
             14.0     0.00015                          / TABLE NO. 01
```

```
--
--        POLYMER    POLYMER
--        POLCON     POLRATIO
--        -------    --------
              0.0     0.00000
              3.0     0.00004
              5.0     0.00006
              7.0     0.00008
              8.0     0.00009
             10.0     0.00011                                  / TABLE NO. 02

              0.0     0.00000
              2.0     0.00003
              4.0     0.00005
              6.0     0.00007
              8.0     0.00009
             10.0     0.00011
             12.0     0.00012
             14.0     0.00015                                  / TABLE NO. 01
--
--        POLYMER    POLYMER
--        POLCON     POLRATIO
--        -------    --------
              0.0     0.00000
              3.0     0.00004
              5.0     0.00006
              7.0     0.00008
              8.0     0.00009
             10.0     0.00011                                  / TABLE NO. 02
```

Here the first PLYATEMP keyword defines the temperature to be 60 oF for the subsequent two polymer rock adsorption tables, assuming NTSFUN equals four and NSSFUN is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section. The next PLYATEMP keyword defines the temperature to be 120 oF for the subsequent two polymer rock adsorption tables.

8.3.203 PLYCAMAX - DEFINE POLYMER-ROCK MAXIMUM ADSORPTION BY CELL

Description

The PLYCAMAX keyword defines the maximum polymer-rock adsorption value used in the calculation of the resistance factor for the water phase by individual grid block, for when the Polymer option has been activated by the POLYMER keyword in the RUNSPEC section. See the POLMAX parameter on the PLYROCK keyword in the PROPS section for setting the property for the whole grid.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.204 PLYDHFLF - DEFINE POLYMER THERMAL DEGRADATION HALF-LIFE TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PLYDHFLF keyword defines the polymer thermal degradation half-life with respect to temperature functions for when the polymer option has been activated by the POLYMER keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	A columnar vector of real monotonically increasing down the column values that defines the polymer thermal degradation temperature.			
		°F	°C	°C	None
2	POLHFLF	A columnar vector of real values that defines the corresponding polymer half-life.			
		days	days	hours	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.102: PLYDHFLF Keyword Description

Example

```
--
--       POLYMER THERMAL DEGRADATION HALF-LIFE TABLE
--
PLYDHFLF
--       POLYMER    POLYMER
--       TEMP       HALF-LIFE
--       -------    ---------
             0.0     365.000
            40.0     200.000
            80.0     150.000
           120.0     100.000                              / TABLE NO. 01
--       POLYMER    POLYMER
--       TEMP       HALF-LIFE
--       -------    --------
             0.0     365.000
            50.0     175.000
            75.0     140.000
           100.0     120.000
           125.0      90.000
           150.0      85.000                              / TABLE NO. 02
```

The example defines two polymer thermal degradation half-life tables, based on the NTPVT variable on the TABDIMS keyword in the RUNSPEC section being equal to two and NPPVT variable on the same keyword being greater than or equal to six.

8.3.205 PLYESAL – DEFINE POLYMER EFFECTIVE SALINITY COEFFICIENT

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, PLYESAL, defines the polymer effective salinity coefficient as well as enabling the effective salinity calculation for polymer adsorption. The keyword should only be used if the BRINE keyword has been declared to activate the brine phase, the ECLMC keyword to enable the Multi-Component Brine model, and the POLYMER keyword has been used to activate the polymer phase. All three keywords are in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.206 PLYKRRF – DEFINE POLYMER ROCK PERMEABILITY REDUCTION BY CELL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PLYKRRF keyword defines the polymer rock permeability reduction factor to the water phase by individual cell, for when the Polymer option has been activated by the POLYMER keyword in the RUNSPEC section. PLYKRRF should consist of an array of real positive values that are greater than or equal to one. See the PERMFAC parameter on the PLYROCK keyword in the PROPS section for setting the property for the whole grid.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.207 PLYMAX - DEFINE POLYMER-SALT VISCOSITY MIXING CONCENTRATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PLYMAX keyword defines maximum polymer and salt concentrations that are to be used in the mixing parameter calculation of the fluid component viscosities, for when the Polymer option has been activated by the POLYMER keyword in the RUNSPEC section.

Note that If the BRINE option has not be activated by the BRINE keyword in the RUNSPEC section, then the salt concentrations in the second column are ignored.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	POLCON	A real value that defines the polymer concentration in the solution which is used to calculate maximum polymer fluid component viscosity.			
		lb/stb	kg/sm^3	gm/scc	None
2	SALTCON	A real value that defines the salt concentration in the solution which is used to calculate maximum polymer fluid component viscosity. Note that If the BRINE option has not been activated by the BRINE keyword in the RUNSPEC section, then this variable is ignored; however, there should still be dummy entries in this case. This variable is ignored as the BRINE and POLYMER combination is not implemented in OPM Flow.			
		lb/stb	kg/sm^3	gm/scc	None

Notes:

1) The keyword is followed by NPLMIX tables as declared on the REGDIMS keyword in the RUNSPEC section, for each rock region. There should be only one row per table.
2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.103: PLYMAX Keyword Description

Note

Currently, combining the BRINE and POLYMER models is not implemented in OPM Flow, and therefore SALTCON parameter on the PLYMAX keyword is ignored.

Example

```
--
--       POLYMER-SALT VISCOSITY MIXING CONCENTRATIONS
--
PLYMAX
--       POLYMER    SALT
--       POLCON     SALTCON
--       -------    --------
         0.0100      0.0500                              / TABLE NO. 01
         0.0075      0.0400                              / TABLE NO. 02
         0.0050      0.0300                              / TABLE NO. 03
```

The above example defines three polymer-salt viscosity mixing concentrations, based on the NPLMIX variable on the REGDIMS keyword in the RUNSPEC section being equal to three.

8.3.208 PLYMWINJ – POLYMER MOLECULAR WEIGHT MODEL THROUGHPUT AND VELOCITY TABLE

Description

This keyword, PLYMWINJ, describes the relationship of the injected polymer molecular weight as a function of polymer throughput and polymer velocity, for the simulator's Polymer Molecular Weight Transport option, that uses the polymer molecular weight in calculating the polymer viscosity. The table is a two dimensional table that relates the polymer throughput values and velocity values to derive the resulting molecular weight of the injected polymer, which is then used via the PLYVHM keyword in the PROPS section, to derive the polymer molecular weight scaled viscosity.

This keyword should only be used if the POLYMER and POLYMW keywords in the RUNSPEC section are also activated.

Note

This is an OPM Flow specific keyword that employs an alternative polymer flood model based on a Polymer Molecular Weight Transport equation, that is not available in the commercial simulator.

The model has been tested using metric units; however, using either field or laboratory units with the option should be considered experimental.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1-1	PLYMWNUM	A positive integer value greater than zero and less than or equal to the NTPMWINJ variable, as defined on the PINTDIMS keyword in the RUNSPEC section, that defines the PLYMWINJ Polymer Molecular Weight Model throughput and velocity table number.			None
2-1	THRUPUT	A real positive monotonically increasing vector, that defines the polymer throughput values. The first entry should be zero to define a no throughput data set, and each vector record should be on a separate line terminated by a "/".			None
		feet^3/feet^2	m^3/m^2	cm^3/cm^2	
3-1	VELOCITY	A real positive monotonically increasing vector, that defines the polymer velocity values. The first entry should be zero to define a no velocity data set, and each vector record should be on a separate line terminated by a "/".			None
		feet/day	m/day	cm/hour	

No.	Name	Description			Default
		Field	Metric	Laboratory	
4-1	POLYMW	A series of real positive vectors representing the polymer molecular weights for all combinations of the polymer throughput values (THRUPUT) and velocity values (VELOCITY), organized as a series of vectors POLYMW(THRUPUT,VELOCITY). Thus, the first vector represents the molecular weights of the first THRUPUT value and each entry in the vector is the corresponding molecular weight of the associated VELOCITY vector. Each vector should be on a separate line and should be terminated by a "/". Thus, if THRUPUT has three entries and VELOCITY has four, then there should be three vectors, with each vector containing four elements representing molecular weight values, as a function of THRUPUT and VELOCITY.			None
		lb/lb-M	kg/kg-M	gm/gm-M	

Notes:

1) The keyword should be terminated by a "/", but may be repeated up to NTPMWINJ times, as per the PINTDIMS keyword in the RUNSPEC section, to allow for the input of multiple tables.

Table 8.104: PLYMWINJ Keyword Description

Unlike other PROPS section table keywords, that enable multiple tables following the keyword to be entered, the PLYMWINJ keyword requires that the keyword itself must be repeated for each table, as is shown in the example on the following page.

See also the WPMITAB keyword in the SCHEDULE section, that assigns the PLYMWINJ tables to the water injection wells, as well as the SKPRWAT, SKPRPOLY, and PLYVMH keywords, in the PROPS section, that are the additional property keywords required for the Polymer Molecular Weight Transport option.

The WSKPTAB keyword in the SCHEDULE section may be used to assign the SKPRPOLY and SKPRWAT tables to water injections wells, that enable the calculation of the wellbore skin pressure based on the fluids being injected.

Note that the standard polymer property data keywords: PLYROCK, PLYADS, PLYMAX, etc., are still required to fully describe the polymer fluid.

Example

Given NTPMWINJ equals two on the PINTDIMS keyword in the RUNSPEC section, then two PLYWINJ tables are required to be entered:

```
--
--        POLYMER MOLECULAR WEIGHT MODEL THROUGHPUT AND VELOCITY TABLE
--        (OPM FLOW PROPS KEYWORD)
--
PLYMWINJ
          1                              / TABLE NUMBER

          20.0    19.0    18.0    16.0  / POLYMW(OUTPUT=1, VELOCITY=1 TO N)
          20.0    16.0    14.0    12.0  / POLYMW(OUTPUT=2, VELOCITY=1 TO N)
          20.0    12.0     8.0     4.0  / POLYMW(OUTPUT=3, VELOCITY=1 TO N)
/
PLYMWINJ
          2                              / TABLE NUMBER
--
--        THROUGHPUT VALUES
--
          0.0     200.0   400.0          /
--
--        VELOCITY VALUES
--
          0.0     50.0    70.0    100.0 /
--
--        POLYMW VALUES
--
          20.0    19.0    18.0    16.0  / POLYMW(OUTPUT=1, VELOCITY=1 TO N)
          20.0    16.0    14.0    12.0  / POLYMW(OUTPUT=2, VELOCITY=1 TO N)
          20.0    12.0     8.0     4.0  / POLYMW(OUTPUT=3, VELOCITY=1 TO N)
/
```

As mentioned previously, the PLYMWINJ keyword requires that the keyword itself must be repeated for each table, as is shown in the above example.

8.3.209 PLYRMDEN - DEFINE POLYMER MODEL IN SITU ROCK DENSITY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PLYRMDEN keyword defines the in situ rock density at reservoir conditions by individual cell, for when the Polymer option has been activated by the POLYMER keyword in the RUNSPEC section. PLYRMDEN should consist of an array of real positive values. See the DENSITY parameter on the PLYROCK keyword in the PROPS section for setting the property for the whole grid.

8.3.210 PLYROCK - DEFINE POLYMER-ROCK PROPERTIES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PLYROCK keyword defines rock properties for when the Polymer option has been activated by the POLYMER keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PSPACE	A real positive value that is greater than or equal to zero and less the maximum water saturation and less than one, that defines available pore space for this rock type.			
		dimensionless	dimensionless	dimensionless	None
2	PERMFAC	A real positive value that is greater than or equal to one that defines decrease in the rock permeability to the water phase when the maximum amount of polymer has been adsorbed.			
		dimensionless	dimensionless	dimensionless	None
3	DENSITY	A real value that defines the rock in-situ density, that is at reservoir conditions.			
		lb/rb	kg/rm^3	gm/rcc	None
4	ADINDX	A positive integer of 1 or 2 that defines the polymer desorption option. 1) then polymer desorption may occur by retracing the polymer adsorption isotherm when the local polymer concentration in the solution decreases. 2) then no polymer desorption may occur.			
		dimensionless 1	dimensionless 1	dimensionless 1	Defined
5	POLMAX	A real positive non-zero value that defines the maximum polymer adsorption to be used in the calculation of the resistance factor for the water phase.			
		lb/lb	kg/kg	gm/gm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section, for each polymer flooding region. There should be only one row per table.
2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.105: PLYROCK Keyword Description

Example

```
--
--       POLYMER-ROCK PROPERTIES
--
PLYROCK
--       PORE      PERM      INSITU    DESORP  MAX
--       SPACE     FACTOR    DENSITY   OPTN    POLY
--       ------   --------   -------   ------  -------
         0.1200    1.7500    1800.0      1     0.00012     / TABLE NO. 01
         0.1300    1.8500    1980.0      2     0.00015     / TABLE NO. 02
         0.1500    1.9500    2005.0      1     0.00014     / TABLE NO. 03
```

The above example defines three polymer-rock tables, based on the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section being equal to three.

There is no terminating "/" for this keyword.

8.3.211 PLYSHEAR – ACTIVATE AND DEFINE POLYMER SHEARING PARAMETERS

Description

The PLYSHEAR keyword activates and defines the polymer shear thinning-thickening option for when the polymer option has been activated by the POLYMER keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	VELOCITY	A columnar vector of real monotonically increasing down the column values that defines the water-polymer flow velocity. The VELOCITY value for the first row in the table should be zero.			
		feet/day	m/day	cm/hour	None
2	VISFAC	A columnar vector of real values that defines a factor that scales the effective water and polymer viscosities for when shear thinning-thickening of the polymer occurs. Normally VISFAC value for the first row in the table should be one.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.106: PLYSHEAR Keyword Description

Example

```
--
--       ACTIVATE AND DEFINE POLYMER SHEARING PARAMETERS
--
PLYSHEAR
--       WAT-POLY    VISCOSITY
--       VELOCITY    FACTOR
--       --------    ---------
             0.0       1.000
             1.0       0.900
             3.0       0.800
             6.0       0.700                          / TABLE NO. 01
--       WAT-POLY    VISCOSITY
--       VELOCITY    FACTOR
--       --------    ---------
             0.0       1.000
             1.0       0.900
             2.0       0.800
             4.0       0.750
             6.0       0.700
             8.0       0.650                          / TABLE NO. 02
```

The above example activates the polymer shear thinning-thickening option and defines two polymer shear thinning-thickening tables, based on the NTPVT variable on the TABDIMS keyword in the RUNSPEC section being equal to two and NPPVT variable on the same keyword being greater than or equal to six.

8.3.212 PLYSHLOG - ACTIVATE AND DEFINE THE POLYMER SHEARING LOGARITHMIC PARAMETERS

Description

This keyword activates and defines the parameters for the logarithm-based polymer shear thinning/thickening option.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1-1	POLCON	A real positive value that defines the reference polymer concentration for the VELOCITY and VISFAC data for this keyword.			
		lb/stb	kg/sm^3	gm/scc	None
1-2	SALTCON	A real positive value that defines the reference salt concentration for the VELOCITY and VISFAC data for this keyword. Note that If the BRINE option has not been activated by the BRINE keyword in the RUNSPEC section, then this variable is ignored. This variable is ignored as the BRINE option is not implemented in OPM Flow.			
		lb/stb	kg/sm^3	gm/scc	None
1-3	TEMP	A real positive value defines the reference polymer temperature for the VELOCITY and VISFAC data for this keyword. Note that If the TEMP option has not been activated by the TEMP keyword in the RUNSPEC section, then this variable is ignored. This variable is ignored as the TEMP and POLYMER options combination is not implemented in OPM Flow.			
		°F	°C	°C	None
1-4	/	Record terminated by a "/"			Not Applicable
2-1	VELOCITY	A columnar vector of real monotonically increasing down the column values that defines the water-polymer flow velocity for the reference conditions of POLCON, SALTCON and TEMP. The VELOCITY value for the first row in the table should be a very small value that is greater than zero and less than 1 x 10-6.			
		feet/day	m/day	cm/hour	None
2-2	VISFAC	A columnar vector of real positive values that define the dimensionless shear effect multiplier for the given VELOCITY entry for the reference conditions of POLCON, SALTCON and TEMP. Normally VISFAC value for the first row in the table should be one.			
		dimensionless	dimensionless	dimensionless	None
1-4	/	Record terminated by a "/"			Not Applicable

No.	Name	Description			Default
		Field	Metric	Laboratory	

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must be entered with two records, with entries 1-1, 1-2, 1-3 and 1-4 representing record number one and 2-1, 2-2 and 2-3 representing record number two in the "No." column in this table.
3) Each of the records are terminated by a "/" and is explicitly shown in the above rows.
4) For record number two a minimum of two rows and a maximum of NPPVT rows, as declared on the TABDIMS keyword in the RUNSPEC section, are required.
5) There is no "/" terminator for the keyword.

Table 8.107: PLYSHLOG Keyword Description

See the PLYSHEAR keyword for the alternative polymer shear thinning/thickening option that is also implemented in OPM Flow.

Example

The following example show how to enter two PLYSHLOG tables given that the NTPVT variable on the TABDIMS keyword in the RUNSPEC section is set equal to two.

```
--
--        POLYMER SHEARING LOGARITHMIC PARAMETERS
--
PLYSHLOG
--        REF          REF         REF
--        POLCON       SALTCON     TEMP
--        --------     -------     ----
          0.5
/
--
--        VELOCITY     VISFAC
--        --------     -------
          0.0000001     1.00
          0.000001      1.10
          0.0001        1.30
          0.001         1.47
          0.01          1.67
          0.1           2.00
          1.0           2.20
          10.0          2.30
          100.0         2.40
          1000.0        2.40
                                                    / TABLE NO. 01
--        REF          REF         REF
--        POLCON       SALTCON     TEMP
--        --------     -------     ----
          0.5
/
```

```
--
--        VELOCITY    VISFAC
--        --------    -------
          0.0000001    1.00
          0.000001     1.10
          0.0001       1.35
          0.001        1.57
          0.01         1.87
          0.1          2.20
          1.0          2.40
          10.0         2.60
          100.0        2.65
          1000.0       2.65
                                    / TABLE NO. 02
```

The example activates the polymer logarithmic shear thinning-thickening option and defines two polymer shear thinning-thickening tables, based on the NTPVT variable on the TABDIMS keyword in the RUNSPEC section being equal to two and NPPVT variable on the same keyword being greater than or equal to ten.

8.3.213 PLYTRRF – DEFINE POLYMER ROCK PERMEABILITY REDUCTION VERSUS TEMPERATURE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PLYTRRF keyword defines the polymer rock permeability reduction factor to the water phase as a function of temperature, for when the Polymer option has been activated by the POLYMER keyword in the RUNSPEC section. See the PLYTRRF keyword for the options on how this data is used in the polymer model and the PERMFAC parameter on the PLYROCK keyword for setting the property for the whole grid for a constant temperature. Both keywords are in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.214 PLYTRRFA – DEFINE POLYMER ROCK PERMEABILITY REDUCTION VERSUS TEMPERATURE OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PLYTRRFA keyword defines the how the polymer rock permeability reduction factor to the water phase as a function of temperature data, entered via the PLYTRRA keyword in the PROPS section, should be used. This keyword should only be used if the Polymer option has been activated by the POLYMER keyword in the RUNSPEC section. See the PERMFAC parameter on the PLYROCK keyword in the PROPS section for setting the property for the whole grid for a constant temperature.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.215 PLYVISC – DEFINE POLYMER VISCOSITY SCALING FACTORS

Description

PLYSVISC defines the polymer viscosity scaling factors used to determine the relationship of pure water viscosity with respect to increasing polymer concentration within a grid block. The polymer option must be activated by the POLYMER keyword in the RUNSPEC section in order to use this keyword.

The BRINE option in the RUNSPEC should be deactivated if this keyword is to be used.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	POLCON	A columnar vector of real monotonically increasing down the column values that defines the polymer concentration in the solution surrounding the rock. The first entry should be zero to define a no polymer concentration.			
		lb/stb	kg/sm^3	gm/scc	None
2	VISFAC	A columnar vector of real increasing or equal values that defines a factor that scales the effective viscosity of the solution for the given POLCON entry. Normally VISFAC value for the first row in the table should be one.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.108: PLYVISC Keyword Description

Example

```
--
--       POLYMER VISCOSITY SCALING FACTOR TABLES
--
PLYVISC
--       POLYMER     VISCOSITY
--       POLCON      VISFAC
--       --------    ---------
          0.0000       1.000
          0.0002      10.000
          0.0004      20.000
          0.0008      40.000                          / TABLE NO. 01
```

```
--       POLYMER     VISCOSITY
--       POLCON      VISFAC
--       --------    ---------
          0.0000       1.000
          0.0003      10.000
          0.0005      20.000
          0.0007      40.000
          0.0009      45.000
          0.0011      55.000                          / TABLE NO. 02
```

The example defines two polymer viscosity scaling factor tables, based on the NTPVT variable on the TABDIMS keyword in the RUNSPEC section being equal to two and NPPVT variable on the same keyword being greater than or equal to six.

8.3.216 PLYVISCS – DEFINE POLYMER-SALT VISCOSITY SCALING FACTORS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PLYSVISCS defines the polymer-salt viscosity scaling factor tables applied to pure water that are used to determine the viscosity of a polymer-salt mixture with respect to increasing polymer concentration within a grid block. The polymer option must be activated by the POLYMER keyword, as well as the brine phase declared by the BRINE keyword in the RUNSPEC section in order to use this keyword. However the ECLM keyword in the RUNSPEC must not be used with this keyword.

See also the PLYVSCST keyword in the PROPS section to enter polymer viscosity scaling factor data that is dependent on both salt and reservoir temperature.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.217 PLYVISCT – DEFINE POLYMER-TEMPERATURE VISCOSITY SCALING FACTORS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PLYSVISCT defines the polymer-temperature viscosity scaling factor tables applied to pure water that are used to determine the viscosity of the polymer at a given temperature with respect to increasing polymer concentration within a grid block. Both the polymer option must be activated by the POLYMER keyword and the temperature option invoked by the TEMP keyword in the RUNSPEC section in order to use this keyword. However the BRINE keyword in the RUNSPEC must not be used with this keyword, that is the salt sensitivity options should be deactivated.

See also the PLYVSCST keyword in the PROPS section to enter polymer viscosity scaling factor data that is dependent on both salt and reservoir temperature.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.218 PLYVMH - POLYMER MOLECULAR WEIGHT MODEL POLYMER VISCOSITY CONSTANTS

Description

This keyword, PLYVMH, defines the constants used to calculate viscosity of the polymer solution as a function of the polymer molecular weight and the polymer concentration, for the simulator's Polymer Molecular Weight Transport option, that uses the polymer molecular weight in calculating the polymer viscosity. The keyword consists of a series of row vectors, which each vector having four elements, that define the constants used in calculating the polymer viscosity

This keyword should only be used if the POLYMER and POLYMW keywords in the RUNSPEC section are also activated.

Note

This is an OPM Flow specific keyword that employs an alternative polymer flood model based on a Polymer Molecular Weight Transport equation, that is not available in the commercial simulator.

The model has been tested using metric units; however, using either field or laboratory units with the option should be considered experimental.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	MHK	The Mark-Houwink K polymer specific constant in the Mark-Houwink equation, see equation (8.81).			None
			ml/g		
2	MHA	The Mark-Houwink exponent parameter a, in the Mark-Houwink equation, see equation (8.81).			None
		dimensionless	dimensionless	dimensionless	
3	GAMMA	The γ intrinsic water-polymer viscosity constant in the Huggins equation, see equation (8.83).			None
4	KAPPA	The κ intrinsic water-polymer viscosity constant in the Huggins equation, see equation (8.83).			None

Notes:

1) The keyword is followed by NPLYVHM records as declared on the PINTDIMS keyword in the RUNSPEC section, with each record terminated by a "/" and the keyword itself should be terminated by a "/".

Table 8.109: PLYVMH Keyword Description

The high molecular weight of polymers greatly increase the viscosity of the injected water in which they are dissolved, thus adjusting the mobility ration of the displacing phase. The increase in viscosity is caused by strong internal friction between the randomly coiled and swollen macro molecules and the surrounding

water molecules. And is dependent on both the nature of the polymer and the injected water acting as the solvent. There are several formulations of viscosity associated with polymer rheology, namely:

Relative viscosity is defined as:

$$\eta_{rel} = \frac{\eta}{\eta_s} \tag{8.77}$$

where:

η_{rel} = is the relative viscosity,
η = is the viscosity of the solution, and
η_s = is the viscosity of the solvent (injected water).

Specific viscosity is defined as:

$$\begin{aligned} \eta_{\text{sp}} &= \frac{(\eta - \eta_s)}{\eta_s} \\ &= \frac{\eta}{\eta_s} - 1 \\ &= \eta_{rel} - 1 \end{aligned} \tag{8.78}$$

where:

η_{sp} = is the specific water-polymer viscosity, and
η_s = is the viscosity of the solvent (injected water).

Reduced Specific Viscosity is given by:

$$\begin{aligned} \eta_{\text{red}} &= \frac{\eta_{\text{sp}}}{C_p} \\ &= \frac{(\eta_{rel} - 1)}{C_p} \end{aligned} \tag{8.79}$$

where:

η_{red} = is the reduced specific water-polymer viscosity, and
C_p = is the polymer concentration.

Finally, the Intrinsic Velocity, which is defined as a measure for the internal friction in polymer solutions at the limit of zero polymer concentration. Thus, this quantity describes the effect of completely separated polymer chains on the solution viscosity, and is defined as:

$$\begin{aligned} [\eta] &= \lim_{C_p \to 0} \frac{\eta_{\text{sp}}}{C_p} \\ &= \lim_{C_p \to 0} \frac{\eta - \eta_0}{\eta_0 C_p} \end{aligned} \tag{8.80}$$

where:

$[\eta]$ = is the intrinsic water-polymer viscosity and describes the increase in viscosity arising from an individual polymer chain and is a measure of the polymers' thickening power, and
η_o = zero-shear viscosity.

For any given solvent pair, the intrinsic viscosity increases as the molecular weight of the polymer increases; here, the *Mark-Houwink equation*, also known as the Mark-Houwink-Staudinger equation[215], [216], and [217] is used to calculate [η], that is:

$$[\eta] = K \cdot M_w^a \tag{8.81}$$

where:

K = is the polymer specific constant in the Mark-Houwink equation, the MHK parameter in Table 8.109,
M_w = is the polymer molecular weight, and
a = the exponent constant in the Mark-Houwink equation, the MHA parameter in Table 8.109.

The Mark-Houwink parameters can be determined from a double logarithmic plot of intrinsic viscosity versus molecular weight which yields straight lines, that is:

$$\ln([\eta]) = \ln(K) + a \times \ln(M_w) \tag{8.82}$$

OPM Flow uses a form of the Huggins[218] equation to calculate the polymer apparent viscosity, as shown below:

$$\frac{\eta_0}{\eta_s} = 1 + \gamma\left(X + \kappa X^2\right) \quad \text{where} \quad X = [\eta] C_p \tag{8.83}$$

where:

γ = a user defined constant, GAMMA in Table 8.109, and
κ = a user defined constant, KAPPA in Table 8.109.

Which can be used to calculate the zero-shear viscosity, η_0, based on the quadratic function in equation (8.83) time polymer concentration(C_p) and polymer intrinsic viscosity described in equation (8.81).

In terms of the keyword units, given the intrinsic viscosity in ml/g, polymer concentration in kg/m3, and the molecular weight as kg/kg-M, then equation (8.81) becomes:

$$[\eta] = K\left(M_w \cdot 1.0\times10^{-3}\right)^a \cdot 1.0\times10^{-3} \tag{8.84}$$

and equation (8.83) becomes:

$$\frac{\eta_0}{\eta_s} = 1 + \gamma\left(X + \kappa X^2\right) \quad \text{where} \quad X = 1.0\times10^{-6}[\eta] C_p \tag{8.85}$$

Note that the model does not account for non-Newtonian flow; the apparent viscosity is simply set equal to the zero-shear viscosity, and that the model only considers the full mixing between the polymer and water.

[218] *Huggins, M. L. 1942. The viscosity of dilute solutions of long-chain molecules. IV. Dependence on concentration.» Journal of the American Chemical Society 64 (11): 2716-2718.*

See also the PLYMWINJ keyword in the PROPS section, that describes the relationship of the injected polymer molecular weight as a function of polymer throughput and polymer velocity. Note that the standard polymer property data keywords: PLYROCK, PLYADS, PLYMAX, etc., are still required to fully describe the polymer fluid.

Example

Given NPLYVMH equals two on the PINTDIMS keyword in the RUNSPEC section, then:

```
--
--       POLYMER MOLECULAR WEIGHT MODEL POLYMER VISCOSITY CONSTANTS
--       (OPM FLOW PROPS KEYWORD)
--
--       MHK     MHA     VISC    VISC
--       CONST   EXPON   GAMMA   KAPPA
PLYVMH
         0.02    0.50    0.40    0.60                    /
         0.03    0.51    0.42    0.63                    /
/
```

Two sets of data should be entered with the PLYVMH keyword, as shown above.

8.3.219 PLYVSCST – DEFINE POLYMER-SALT-TEMPERATURE VISCOSITY SCALING FACTORS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PLYVSCST defines the polymer-salt-temperature viscosity scaling factor tables applied to pure water that are used to determine the viscosity of the polymer at a given salt concentration and for a given temperature, with respect to increasing polymer concentration within a grid block. Both the polymer option must be activated by the POLYMER keyword and the temperature option invoked by the TEMP keyword in the RUNSPEC section in order to use this keyword. In addition, the BRINE keyword in the RUNSPEC must also be invoked. The keyword is used in conjunction with the SALTNODE keyword to define the various salt concentrations and the TEMPNODE keyword to define the various reservoir temperatures. Both keywords are in the PROPS section.

See also the PLYVISCS keyword in the PROPS section to enter polymer viscosity scaling factor data that is dependent just salt concentration and the PLYVISCT keyword in the PROPS section to enter polymer viscosity scaling factor data that is dependent just on reservoir temperature.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.220 PMAX – MAXIMUM AND MINIMUM PRESSURE FOR TOTAL COMPRESSIBILITY CHECK

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The PMAX keyword defines the maximum and minimum pressures expected to be encountered during the run. The data is used to perform the PVT total compressibility check that ensures that the total compressibility of a mixture of oil-gas, for when the gas-oil ratio is increasing for an oil, or the condensate gas ratio is increasing for a gas condensate, is positive respect to pressure. The total compressibility check is used to ensure that the entered oil and gas PVT data is consistent. If the check fails for given oil-gas mixture at a given pressure, resulting in a negative total compressibility, then this will result in numerical instabilities in the run causing this simulator difficulties in converging to a solution.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.221 PMISC – DEFINE MISCIBILITY VERSUS PRESSURE TABLES

Description

PMISC defines the transition between immiscible and miscible displacement as a function of oil pressure tables, for when the MISCIBLE keyword in the RUNSPEC section has be activated. If this keyword is absent from the input deck and MISCIBLE keyword in the RUNSPEC keyword has been activated, then miscibility is independent of the oil phase pressure.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A columnar vector of real monotonically increasing down the column values that defines the oil phase pressure.			
		psia	barsa	atma	None
2	MISC	A columnar vector of real equal or increasing down the column values that defines the corresponding miscibility factor. MISC is a scaling that should lie be zero and one, where zero means no miscibility and one means full miscibility.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTMISC tables as declared on the MISCIBLE keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSMISC rows as declared on the MISCIBLE keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.110: PMISC Keyword Description

Example

```
--
--       MISCIBILITY VERSUS PRESSURE TABLES
--
PMISC
--       OIL        MISCIBILE
--       PRESS      FACTOR
--       -------    ---------
          1000.0       0.000
          2000.0       0.250
          3000.0       1.000
          4000.0       1.000                          / TABLE NO. 01
--       OIL        MISCIBILE
--       PRESS      FACTOR
--       -------    ---------
          1500.0       0.000
          2000.0       0.000
          2500.0       0.250
          3000.0       0.350
          3500.0       1.000
          4000.0       1.000                          / TABLE NO. 02
```

The above example defines two miscibility versus pressure tables assuming NTMISC equals two and NSMISC is greater than or equal to six on the MISCIBLE keyword in the RUNSPEC section.

8.3.222 PPCWMAX – DEFINE SWATINIT CALCULATED CAPILLARY PRESSURE CONSTRAINTS

Description

The PPCWMAX keyword defines the maximum capillary pressure allowed when scaling the capillary pressure tables to match the inputted SWATINIT array. This is primary used for when the SWATINIT array has values of water saturation above the connate water saturation significantly outside than capillary pressure transition zone, that is high on the structure. In this case OPM Flow may generate large values for the capillary pressure which may result in numerical converge problems. This keyword sets the maximum allowable calculated capillary pressure and how the water saturation should be treated when the limit is exceeded.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PCWO	A columnar vector of real values that defines the maximum allowable capillary pressure for each SATNUM region. The default value of infinity means there is no limit applied.			
		psia	barsa	atma	Infinity
2	OPTN	A columnar vector of character strings that should be set to: 1) NO: To ignore the SWATINIT value for the offending cell for when PCWO is exceeded. In this cases the capillary pressure for the block is set to the maximum (PCWO) and the water saturation is re-calculated based on PCWO. 2) YES: To set the SWATINIT value to the connate water saturation for the offending cell for when PCWO is exceeded. In this case the capillary pressure is set to the maximum value of the appropriate SATNUM table and the initial water saturation is calculated to be consistent with the tables maximum capillary pressure. This results in the capillary pressures not being re-scale for the offending cell.			No

Notes:

1) The keyword is followed by NTSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each row show contain two values representing PCWO and OPTN values.
3) Each row is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.111: PPCWMAX Keyword Description

Note

Using this keyword to limit the re-scaled grid block capillary pressure values will effect the fluids in-place when the simulator has to re-calculate values due to the capillary pressure limit being exceeded.

In addition, the high grid block capillary pressures may be indicative of an inconsistency between the tabular SATNUM capillary pressure values and the provided SWATINIT array water saturations. This inconsistency may be a result of the SWATINIT array being derived using a saturation height function, as is customary in static modeling software, and the numerical models tabulated capillary pressure. Rather than resetting the maximum calculated capillary pressure using the PPCWMAX keyword, it may be more appropriate to investigate the reason for the high capillary pressures values first, prior to applying the keyword.

Example

```
--
--       SET MAXIMUM PC FOR SWATINIT INITIALIZATION
--       MAX       MATCH
--       PC        SWATINIT
--       --------  --------
PPCWMAX
         100.0     YES                                    / TABLE NO 01
         125.0     YES                                    / TABLE NO 02
         135.0     YES                                    / TABLE NO 03
```

The above example sets the maximum capillary pressure for three saturation regions to 100, 125 and 135 with SWATINIT reset to the connate water saturation for when the capillary pressure limit is exceeded.

8.3.223 PROPS - DEFINE THE START OF THE PROPS SECTION OF KEYWORDS

Description

The PROPS activation keyword marks the end of the EDIT section and the start of the PROPS section that defines the key fluid and rock property data for the simulator

There is no data required for this keyword.

Example

```
-- ==========================================================================
--
-- PROPS SECTION
--
-- ==========================================================================
PROPS
```

The above example marks the end of the EDIT section and the start of the PROPS section in the OPM Flow data input file.

8.3.224 PVCDO - OIL PVT PROPERTIES FOR DEAD OIL (CONSTANT COMPRESSIBILITY)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

PVCDO defines the oil PVT properties for dead oil[219] with constant compressibility. If the oil has a constant and uniform dissolved gas concentration, Gas-Oil Ratio ("GOR"), and if the reservoir pressure never drops below the saturation pressure (bubble point pressure), then the model can be run more efficiently by omitting the GAS and DISGAS keywords from the RUNSPEC section, treating the oil as a dead oil, and defining a constant Rs (GOR) value with keyword RSCONST or RSCONSTT in the PROPS section. This results in the model being run as a dead oil problem with no active gas phase. However, OPM Flow takes into account the constant Rs in the calculations and reporting.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	PRESS is a real positive value defining the oil reference pressure for the other parameters for this data set.			
		psia	barsa	atma	None
2	OFVF	OFVF is a real positive value defining the oil formation volume factor (Bo) at the reference pressure.			
		rb/stb	rm^3/sm^3	rcc/scc	None
3	OCOMP	OCOMP is a real positive value defining the oil compressibility (Co) at the oil reference pressure and is defined as: $$C_o = -\frac{1}{B_o}\left(\frac{dB_o}{dP}\right)$$			
		1/psia	1/barsa	1/atma	None
4	OVISC	OVISC is a real positive value defining the oil viscosity (μo) at the oil reference pressure.			
		cP	cP	cP	None
5	OVISCOMP	OVISCOMP is a real positive value defining the oil viscosibility (μoc) at the oil reference pressure and is defined as: $$\mu_{oc} = \frac{1}{\mu_o}\left(\frac{d\mu_o}{dP}\right)$$			
		1/psia	1/barsa	1/atma	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.112: PVCDO Keyword Description

[219] *"Dead" oil is oil that it contains no dissolved gas or a relatively thick oil or residue that has lost its volatile components.*

See also the RSCONST and RSCONSTT keywords to define the constant Rs for dead oil and PVDO as an alternative keyword to enter the dead oil properties.

Example

```
--
--       OIL PVT TABLE FOR DEAD WITH CONSTANT COMPRESSIBILITY
--
PVCDO
--       REF PRES  BO         CO        VISC     VISC
--       PSIA      RB/STB     1/PSIA    CPOISE   GRAD
--       --------  --------   -------   ------   ------
          3840.0    1.080     1.5E-6     1.750    0.0       / TABLE NO. 01
          3840.0    1.100     1.5E-6     1.050    0.0       / TABLE NO. 02
          3840.0    1.120     1.6E-6     0.950    0.0       / TABLE NO. 03
          3840.0    1.140     1.7E-6     0.850    0.0       / TABLE NO. 04
          3840.0    1.160     1.7E-6     0.800    0.0       / TABLE NO. 05
```

The above example defines five dead oil PVT tables with constant compressibility and viscosity, and assumes that NTPVT equals five on the TABDIMS keyword in the RUNSPEC section.

There is no terminating "/" for this keyword.

8.3.225 PVCO - OIL PVT PROPERTIES FOR LIVE OIL

Description

PVCO defines the oil PVT properties for live[220] and the keyword should only be used if the there is both oil and gas phases in the model. This keyword should be used when the DISGAS keyword has be declared in the RUNSPEC section indicating that dissolved gas (more commonly referred to as solution gas) is present in the oil. The keyword may be used for oil-water and oil-water-gas input decks. This is an alternative keyword to the PVTO keyword in the PROPS section that also enables entering live oil PVT data. Here, the PVCO keyword assumes that for the undersaturated oil with a given Gas-Oil Ratio ("GOR" or "Rs"), the oil compressibility is independent of the pressure. Hence, is not necessary to enter the undersaturated oil formation volume factor versus pressure data. Similarly, the viscosity of the same type of oil is assumed to have a pressure independent "viscosibility" derivative, and therefore it is not necessary to enter undersaturated viscosity versus pressure data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped; however, the PVTO keyword in the PROPS section may be used to enter live oil PVT data instead.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	PRESS is a real columnar vector of real monotonically increasing down the column values that defines the oil phase saturation pressure (bubble-point pressure), that defines the RS, oil formation volume factor and the oil viscosity at PRESS.			
		psia	barsa	atma	None
2	RS	RS is a real monotonically increasing down the column values that defines the saturated gas-oil ratio ("GOR") or Rs, for the given value of PRESS.			
		Mscf/stb	sm^3/sm^3	scc/scc	1*
3	OFVF	OFVF is a real positive value defining the oil saturated formation volume factor (Bo) at the saturation pressure PRESS.			
		rb/stb	rm^3/sm^3	rcc/scc	None
4	OVISC	OVISC is a real positive value defining the oil viscosity (μo) at the oil saturated reference pressure, PRESS.			
		cP	cP	cP	1*
5	OCOMP	OCOMP is a real positive value defining the oil compressibility (Co) at the saturated oil reference pressure and is defined as: $$C_o = -\frac{1}{B_o}\left(\frac{dB_o}{dP}\right)$$			
		1/psia	1/barsa	1/atma	1*

[220] *"Live" oil is oil that contains gas in solution, which is normally the case for most conventional oil reservoirs. However, for oil reservoirs classified as heavy oil reservoirs, the in situ dissolved gas may be negligible and oil would then be classified as gas-free oil which is commonly referred to as "dead" oil.*

No.	Name	Description			Default
		Field	Metric	Laboratory	
6	OVISCOMP	OVISCOMP is a real positive value defining the oil viiscosibility (μoc) at the saturated oil reference pressure with the given RS, where (μoc) is defined as: $$\mu_{oc} = -\frac{1}{\mu_o}\left(\frac{d\mu_o}{dP}\right)$$			
		1/psia	1/barsa	1/atma	1*

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Items (2) to (6) may be defaulted, in which case linear interpolation will be used to calculate the missing values. In addition, OVISCOMP, item (6),may be completely defaulted, which sets this data to zero.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.113: PVCO Keyword Description

Example

```
--
--        OIL PVT TABLE FOR LIVE OIL
--
PVCO
--        PSAT       RS         BO        VISC     OIL       OIL

             14.7     0.0010    1.05340   1.7230   3.0E-5    1*
            500.0     0.0890    1.08890   1.1670   1*        1*
           1000.0     0.2060    1.13850   0.8570   1*        1*
           1500.0     0.3360    1.19640   0.6840   1*        1*
           2000.0     0.4750    1.26110   0.5750   1*        1*
           2500.0     0.6220    1.33160   0.5000   1*        1*
           3000.0     0.7750    1.40740   0.4450   1*        1*
           3500.0     0.9330    1.48790   0.4020   1*        1*
           4000.0     1.0960    1.57280   0.3680   1*        1*
           4258.0     1.1800    1.61760   0.3530   1*        1*
           4500.0     1.2630    1.66190   0.3400   1*        1*
           5000.0     1.4340    1.75480   0.3170   1*        1*
           5500.0     1.6060    1.85020   0.2980   1*        1*     / TABLE NO. 01
--
--        PSAT       RS         BO        VISC     OIL       OIL
--        PSIA       MSCF/STB   RB/STB    CPOISE   COMPRES   VISCOS
--        --------   --------   -------   ------   -------   ------
             14.7     0.0010    1.05340   1.7230   3.0E-5    1*
            500.0     0.0890    1.08890   1.1670   1*        1*
           1000.0     0.2060    1.13850   0.8570   1*        1*
           1500.0     0.3360    1.19640   0.6840   1*        1*
           2000.0     0.4750    1.26110   0.5750   1*        1*
           2500.0     0.6220    1.33160   0.5000   1*        1*
           3000.0     0.7750    1.40740   0.4450   1*        1*
           3500.0     0.9330    1.48790   0.4020   1*        1*
           4000.0     1.0960    1.57280   0.3680   1*        1*
           4258.0     1.1800    1.61760   0.3530   1*        1*
           4500.0     1.2630    1.66190   0.3400   1*        1*
           5000.0     1.4340    1.75480   0.3170   1*        1*
           5500.0     1.6060    1.85020   0.2980   1*        1*     / TABLE NO. 02
```

The example defines two live oil PVT tables with constant compressibility above the saturation pressure, and assumes that NTPVT equals two on the TABDIMS keyword in the RUNSPEC section.

8.3.226 PVDG - GAS PVT PROPERTIES FOR DRY GAS

Description

PVDG defines the gas PVT properties for dry gas[221]. If the gas has a constant and uniform vaporized oil concentration, Condensate-Gas Ratio ("CGR"), and if the reservoir pressure never drops below the saturation pressure (dew point pressure), then the model can be run more efficiently by omitting the OIL and VAPOIL keywords from the RUNSPEC section, treating the gas as a dry gas, and defining a constant Rv (CGR) value with keyword RVCONST or RVCONSTT in the PROPS section. This results in the model being run with as a dry gas problem with no active oil (condensate) phase. However, OPM Flow takes into account the constant Rv in the calculations and reporting.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A columnar vector of real monotonically increasing down the column values that defines the gas phase pressure.			
		psia	barsa	atma	None
2	GFVF	A columnar vector of real decreasing down the column values that defines the corresponding gas phase formation volume factor.			
		rb/Mscf	rm^3/sm^3	rcc/scc	None
3	GVISC	A columnar vector of real increasing down the column values that defines the corresponding gas phase viscosity.			
		cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.114: PVDG Keyword Description

Note that provided the first table has been entered, subsequent tables may be defaulted, in this case the prior table is copied to the current table. See the second example for an illustration on how to use this feature.

See also the RVCONST and RVCONSTT keywords to define the constant Rv for dry gas.

[221] *Natural gas that occurs in the absence of condensate or liquid hydrocarbons, or gas that had condensable hydrocarbons removed, is called dry gas. It is primarily methane with some intermediates. The hydrocarbon mixture is solely gas in the reservoir and there is no liquid (condensate surface liquid) formed either in the reservoir or at surface. The term dry indicates that the gas does not contain heavier hydrocarbons to form liquids at the surface conditions. Dry gas typically has GOR's greater than 100,000 scf/stb or 18,000 Sm3/m3.*

Example

The first example below defines two dry gas PVT tables assuming NTPVT equals two and NPPVT is greater than or equal to 22 on the TABDIMS keyword in the RUNSPEC section.

```
--
--        GAS PVT TABLE FOR DRY GAS
--

```

There is no terminating "/" for this keyword.

8.3.227 PVDO – OIL PVT PROPERTIES FOR DEAD OIL

Description

PVDO defines the oil PVT properties for dead oil[222]. If the oil has a constant and uniform dissolved gas concentration, Gas-Oil Ratio ("GOR"), and if the reservoir pressure never drops below the saturation pressure (bubble point pressure), then the model can be run more efficiently by omitting the GAS and DISGAS keywords from the RUNSPEC section, treating the oil as a dead oil, and defining a constant Rs (GOR) value with keyword RSCONST or RSCONSTT in the PROPS section. This results in the model being run as a dead oil problem with no active gas phase. However, OPM Flow takes into account the constant Rs in the calculations and reporting.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A columnar vector of real monotonically increasing down the column values that defines the oil phase pressure.			
		psia	barsa	atma	None
2	OFVF	A columnar vector of real decreasing down the column values that defines the corresponding oil phase formation volume factor.			
		rb/stb	rm^3/sm^3	rcc/scc	None
3	OVISC	A columnar vector of real increasing down the column values that defines the corresponding oil phase viscosity.			
		cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.115: PVDO Keyword Description

Note that provided the first table has been entered, subsequent tables may be defaulted, in this case the prior table is copied to the current table. See the second example for an illustration on how to use this feature.

See also the RSCONST and RSCONSTT keywords to define the constant Rs for dead oil and PVCDO as an alternative keyword to enter the dead oil properties.

[222] *"Dead" oil is oil that it contains no dissolved gas or a relatively thick oil or residue that has lost its volatile components.*

Example

The example below defines two dead oil PVT tables with variable viscosity and compressibility with respect to pressure, and assumes that NTPVT equals two and NPPVT is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section.

```
--
--      OIL PVT TABLE FOR DEAD OIL
--
PVDO
--      PSAT       BO         VISC
--      PSIA       RB/STB     CPOISE
--      --------   -------    ------
           400     1.0102      1.16
          1200     1.0040      1.164
          2000     0.9960      1.167
          2800     0.9880      1.172
          3600     0.9802      1.177
          4400     0.9724      1.181
          5200     0.9646      1.185
          5600     0.9607      1.19                    / TABLE NO. 01
--      --------   -------    ------
           800     1.0255      1.14
          1600     1.0172      1.14
          2400     1.0091      1.14
          3200     1.0011      1.14
          4000     0.9931      1.14
          4800     0.9852      1.14
          5600     0.9774      1.14                    / TABLE NO. 02
```

The second example defines four dead oil PVT tables with variable viscosity and compressibility with respect to pressure, and assumes that NTPVT equals four and NPPVT is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section. Here table two defaults to table one, and table four defaults to table three.

```
--
--      OIL PVT TABLE FOR DEAD OIL
--
PVDO
--      PSAT       BO         VISC
--      PSIA       RB/STB     CPOISE
--      --------   -------    ------
           400     1.0102      1.16
          1200     1.0040      1.164
          2000     0.9960      1.167
          2800     0.9880      1.172
          3600     0.9802      1.177
          4400     0.9724      1.181
          5200     0.9646      1.185
          5600     0.9607      1.19                    / TABLE NO. 01
                                                       / TABLE NO. 02
           800     1.0255      1.14
          1600     1.0172      1.14
          2400     1.0091      1.14
          3200     1.0011      1.14
          4000     0.9931      1.14
          4800     0.9852      1.14
          5600     0.9774      1.14                    / TABLE NO. 03
                                                       / TABLE NO. 04
```

There is no terminating "/" for this keyword.

8.3.228 PVDS - SOLVENT PVT PROPERTIES FOR THE SOLVENT MODEL

Description

PVDS defines the solvent PVT properties for use with SOLVENT option. The solvent is treated as an additional dry gas phase within the model. This keyword should only be used if the SOLVENT model has been invoked in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A columnar vector of real monotonically increasing down the column values that defines the solvent phase pressure.			
		psia	barsa	atma	None
2	GFVF	A columnar vector of real decreasing down the column values that defines the corresponding solvent phase formation volume factor.			
		rb/Mscf	rm^3/sm^3	rcc/scc	None
3	GVISC	A columnar vector of real increasing down the column values that defines the corresponding solvent phase viscosity.			
		cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.116: PVDS Keyword Description

Example

```
--
--       GAS SOLVENT PVT TABLE
--
PVDS
--       PRES     BG          VISC
--       PSIA     RB/MSCF     CPOISE

         1380.0     2.1560    0.0145
         1610.0     1.8316    0.0150
         1840.0     1.5952    0.0155
         2070.0     1.4129    0.0161
         2300.0     1.2700    0.0167
         2372.0     1.2305    0.0169
         2530.0     1.1551    0.0174
         2760.0     1.0621    0.0181
         2990.0     0.9841    0.0189
         3220.0     0.9190    0.0196
         3450.0     0.8638    0.0204
         4500.0     0.6910    0.0242
         6000.0     0.5616    0.0293                    / TABLE N0. 01
--
--       PRES     BG          VISC
--       PSIA     RB/MSCF     CPOISE
--       ------   --------    ------
          700.0     4.6493    0.0138
          920.0     3.4417    0.0140
         1150.0     2.7227    0.0144
         1380.0     2.2522    0.0147
         1610.0     1.9158    0.0151
         1840.0     1.6702    0.0156
         2070.0     1.4805    0.0162
         2300.0     1.3317    0.0167
         2372.0     1.2927    0.0169
         2530.0     1.2119    0.0173
         2760.0     1.1135    0.0180
         2990.0     1.0325    0.0187
         3220.0     0.9637    0.0194
         3450.0     0.9055    0.0201
         4500.0     0.7228    0.0236
         6000.0     0.5837    0.0285                    / TABLE N0. 02
```

The above example defines two solvent PVT tables assuming NTPVT equals two and NPPVT is greater than or equal to 16 on the TABDIMS keyword in the RUNSPEC section.

There is no terminating "/" for this keyword.

8.3.229 PVTG - GAS PVT PROPERTIES FOR WET GAS WITH VAPORIZED OIL

Description

PVTG defines the gas PVT properties for wet gas[223]. This keyword should be used when the VAPOIL keyword has be declared in the RUNSPEC section indicating that that vaporized oil (more commonly referred to as condensate) is present in the wet gas phase. The keyword may be used for gas-water and oil-water-gas input decks that contain the oil and gas phases.

No.	Name		Description			Default
			Field	Metric	Laboratory	
1	PRESS		A real monotonically increasing down the column vector that defines the gas phase pressure, associated with the saturated condensate-gas ratio ("CGR") or Rv, the gas formation volume factor and the gas viscosity for the corresponding pressure for the stated saturated RVS. For a given PRESS the variability of the gas formation volume factor and the gas viscosity with respect to the under-saturated Rv is optionally included as a sub table under RVU, FVFU and VISU columns, that is it is not necessary to repeat PRESS for each sub table entry. However, each sub table must be terminated by a "/". The under saturated Rv entries are optional, except for perhaps the last PRESS entry to define the PVT properties above the initial saturation pressure.			
			psia	barsa	atma	None
2	RVS	RVU	A columnar vector of real positive number for both the saturated (RVS) and under saturated (RVU) Rv sub table entries. The RVS entry on the main table is the saturated CGR at the pressure indicated by PRESS and may be increasing or decreasing in value as PRESS varies. Subsequent under-saturated Rv for a sub table at the given PRESS, as defined by RVU, are monotonically decreasing for entries in a given sub table.			
			stb/Mscf	sm^3/sm^3	scc/scc	None
3	FVFS	FVFU	A columnar vector of real decreasing down the column values that defines the corresponding gas phase formation volume factor for a given pressure (PRESS) and for a given Rv (either RVS or RVU).			
			rb/Mscf	rm^3/sm^3	rcc/scc	None
4	VISS	VISU	VISS a columnar vector of real increasing down the column values that defines the corresponding gas phase viscosity for a given pressure (PRESS) and for a given RVS. VISU a columnar vector of real decreasing from VISS down the column values that defines the corresponding gas phase viscosity for a given pressure (PRESS) and for a given RVU.			None

[223] *Natural gas that contains significant heavy hydrocarbons such as propane, butane and other liquid hydrocarbons is known as wet gas or rich gas. The general rule of thumb is if the gas contains less methane (typically less than 85% methane) and more ethane, and other more complex hydrocarbons, it is labeled as wet gas. Wet gas normally has GOR's less than 100,000 scf/stb or 18,000 Sm3/m3, with the condensate having a gravity greater than 50 oAPI.*

No.	Name		Description			Default
			Field	Metric	Laboratory	
			cP	cP	cP	

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows and NRPVT Rv entries as declared on the TABDIMS keyword in the RUNSPEC section.
3) Apart from the PRESS data there must be same number of entries for each column.
4) Each sub table defining the under saturated gas properties must be terminated by "/".
5) Each main table is terminated by a single "/" on a separate line and there is no "/" terminator for the keyword.

Table 8.117: PVTG Keyword Description

Note that provided the first table has been entered, subsequent tables may be defaulted, in this case the prior table is copied to the current table. See the second example for an illustration on how to use this feature.

Note

If the VAPWAT keyword in the RUNSPEC section is also present in the input deck, then the PVTG keyword in the PROPS section should be used to define the gas properties as function of pressure and RV, assuming water-saturated gas. Also, in this case, the PVTGW keyword, also in the PROPS section, should also be in the input deck. In this case, PVTGW defines the gas properties as function of pressure and RVW, assuming oil-saturated gas.

Example

The first example defines two wet gas PVT tables assuming NTPVT equals two, NPPVT is greater than or equal to eight, and NRPVT greater than or equal to two on the TABDIMS keyword in the RUNSPEC section.

```
--
--       GAS PVT TABLE FOR WET GAS WITH VAPORIZED OIL
--
PVTG
--       PRES       RV           BG           VISC
--       BARSA    SM^3/SM^3    RM^3/SM^3       CPOISE
--      ------    ---------    -------      ------
           20     0.000132      0.042340      0.01344
                  0             0.042310      0.01389      /
           40     0.000124      0.020460      0.01420
                  0             0.020430      0.01450      /
           60     0.000126      0.013280      0.01526
                  0             0.013250      0.01532      /
           80     0.000135      0.009770      0.01660
                  0             0.009730      0.01634      /
          100     0.000149      0.007730      0.01818
                  0             0.007690      0.01752      /
          120     0.000163      0.006426      0.01994
                  0             0.006405      0.01883      /
          140     0.000191      0.005541      0.02181
                  0             0.005553      0.02021      /
          160     0.000225      0.004919      0.02370
                  0             0.004952      0.02163      /
                                                           / TABLE NO. 1
--       PRES       RV           BG           VISC
--       BARSA    SM^3/SM^3    RM^3/SM^3       CPOISE
--      ------    ---------    -------      ------
           20     0.000132      0.042340      0.01344
           40     0.000124      0.020460      0.01420
           60     0.000126      0.013280      0.01526
           80     0.000135      0.009770      0.01660
          100     0.000149      0.007730      0.01818
          120     0.000163      0.006426      0.01994
          140     0.000191      0.005541      0.02181
          160     0.000225      0.004919      0.02370
                  0             0.004952      0.02163      /
                                                           / TABLE NO. 2
```

The second example defines four wet gas PVT tables assuming NTPVT equals four, NPPVT is greater than or equal to eight, and NRPVT greater than or equal to two on the TABDIMS keyword in the RUNSPEC section. Here table two defaults to table one, and table four defaults to table three.

```
--
--        GAS PVT TABLE FOR WET GAS WITH VAPORIZED OIL
--
PVTG
--        PRES        RV           BG           VISC
--        BARSA     SM^3/SM^3     RM^3/SM^3       CPOISE
--       ------     ---------     -------       ------
            20      0.000132      0.042340      0.01344
                    0             0.042310      0.01389      /
            40      0.000124      0.020460      0.01420
                    0             0.020430      0.01450      /
            60      0.000126      0.013280      0.01526

           140      0.000191      0.005541      0.02181
                    0             0.005553      0.02021      /
           160      0.000225      0.004919      0.02370
                    0             0.004952      0.02163      /
                                                             / TABLE NO. 1
                                                             / TABLE NO. 2
--        PRES        RV           BG           VISC
--        BARSA     SM^3/SM^3     RM^3/SM^3       CPOISE
--       ------     ---------     -------       ------
            20      0.000132      0.042340      0.01344
            40      0.000124      0.020460      0.01420
            60      0.000126      0.013280      0.01526
            80     0.000135      0.009770      0.01660
           100      0.000149      0.007730      0.01818
           120      0.000163      0.006426      0.01994
           140      0.000191      0.005541      0.02181
           160      0.000225      0.004919      0.02370
                    0             0.004952      0.02163      /
                                                             / TABLE NO. 3
                                                             / TABLE NO. 4
```

Notice that in both examples there is no terminating "/" for this keyword only for a table and a sub table.

8.3.230 PVTGW - GAS PVT PROPERTIES FOR DRY GAS WITH VAPORIZED WATER

Description

PVTGW defines the gas PVT properties for dry gas[224] with vaporized water. This keyword should be used when the VAPWAT keyword has be declared in the RUNSPEC section indicating that that vaporized water is present in the dry gas phase. The keyword may be used for gas-water and oil-water-gas input decks that contain the dry gas and vaporized water phases.

Note

This is an OPM Flow specific keyword for the simulator's Water Vaporization Model that is activated by declaring that vaporized water is present in the run.

No.	Name		Description			Default
			Field	Metric	Laboratory	
1	PRESS		A real monotonically increasing down the column vector that defines the gas phase pressure, associated with the corresponding saturated water-gas ratio ("WGR") or Rw, the gas formation volume factor, and the gas viscosity for the stated saturated RWS. For a given PRESS the variability of the gas formation volume factor and the gas viscosity with respect to the under-saturated Rw is optionally included as a sub table under RWU, FVFU and VISU columns, that is it is not necessary to repeat PRESS for each sub table entry. However, each sub table must be terminated by a "/". The under saturated Rw entries are optional, except for perhaps the last PRESS entry to define the PVT properties above the initial saturation pressure.			
			psia	barsa	atma	None
2	RWS	RWU	A columnar vector of real positive numbers for both the saturated (RWS) and under saturated (RWU) Rw sub table entries. The RWS entry on the main table is the saturated WGR at the pressure indicated by PRESS and may be increasing or decreasing in value as PRESS varies. Subsequent under-saturated Rw for a sub table at the given PRESS, as defined by RWU, are monotonically decreasing for entries in a given sub table.			
			stb/Mscf	sm^3/sm^3	scc/scc	None
3	FVFS	FVFU	A columnar vector of real decreasing down the column values that defines the corresponding gas phase formation volume factor for a given pressure (PRESS) and for a given Rw (either RWS or RWU).			None

[224] *Natural gas that occurs in the absence of condensate or liquid hydrocarbons, or gas that had condensable hydrocarbons removed, is called dry gas. It is primarily methane with some intermediates. The hydrocarbon mixture is solely gas in the reservoir and there is no liquid (condensate surface liquid) formed either in the reservoir or at surface. The term dry indicates that the gas does not contain heavier hydrocarbons to form liquids at the surface conditions. Dry gas typically has GOR's greater than 100,000 scf/stb or 18,000 Sm3/m3.*

No.	Name		Description			Default
			Field	Metric	Laboratory	
			rb/Mscf	rm^3/sm^3	rcc/scc	
4	VISS	VISU	VISS a columnar vector of real increasing down the column values that defines the corresponding gas phase viscosity for a given pressure (PRESS) and for a given RWS. VISU a columnar vector of real decreasing from VISS down the column values that defines the corresponding gas phase viscosity for a given pressure (PRESS) and for a given RWU.			
			cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows and NRPVT Rw entries as declared on the TABDIMS keyword in the RUNSPEC section.
3) Apart from the PRES data there must be same number of entries for each column.
4) Each sub table defining the under saturated gas properties must be terminated by "/".
5) Each main table is terminated by a single "/" on a separate line and there is no "/" terminator for the keyword.

Table 8.118: PVTGW Keyword Description

Note that provided the first table has been entered, subsequent tables may be defaulted, in this case the prior table is copied to the current table.

Note

If both the VAPWAT and VAPOIL keywords have been declared in the RUNSPEC section indicating that both vaporized water and vaporized oil are present in the wet gas, then the PVTGW keyword should be used along with the PVTG keyword in the PROPS section to fully define the wet gas PVT properties. The PVTGW keyword should be used to define the gas properties as a function of pressure and water-gas ratio (RVW), assuming oil-saturated gas. The PVTG keyword should be used to define the gas properties as a function of pressure and oil-gas ratio (RV), assuming water-saturated gas.

Alternatively, the PVTGWO keyword in the PROPS section may be used instead of the PVTGW and PVTG keywords to fully define the wet gas PVT properties.

See also the PVTG keyword in the PROPS section that defines the wet gas PVT for when vaporized oil is present in the gas phase. Alternatively, the PVTGWO keyword in the PROPS section may be utilized instead of PVTG and PVTGW to fully define the wet gas PVT properties, for when both vaporized oil and water are present in the gas phase.

Example

```
--
--       GAS PVT TABLE FOR DRY GAS WITH VAPORIZED WATER (OPM FLOW KEYWORD)
--

--      ------    ---------    -------       ------
          300     0.000479      0.042340      0.01344
          600     0.000469      0.020460      0.01420
          900     0.000403      0.013280      0.01526
         1200     0.000354      0.009770      0.01660
         1500     0.000272      0.007730      0.01818
         1800     0.000225      0.006426      0.01994
         2100     0.000191      0.005541      0.02181
         2400     0.000163      0.004919      0.02370      /
                                                           / TABLE NO. 2
```

The above example defines two dry gas PVT tables assuming NTPVT equals two and NPPVT is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section.

Notice that there is no terminating "/" for this keyword only for a table and a sub table.

8.3.231 PVTGWO - GAS PVT PROPERTIES FOR WET GAS WITH VAPORIZED WATER AND OIL

Description

PVTGWO defines the gas PVT properties for wet gas[225] with vaporized water and oil. This keyword should be used when the VAPOIL and VAPWAT keywords have been declared in the RUNSPEC section indicating that vaporized oil and water are present in the wet gas phase. The keyword may be used for oil-water-gas input decks that contain the wet gas with vaporized oil and water phases.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Note

This is an OPM Flow specific keyword for the simulator's Water Vaporization Model that is activated by declaring that vaporized water is present in the run.

No.	Name		Description			Default
			Field	Metric	Laboratory	
1	PRESS		A real monotonically increasing down the column vector that defines the gas phase pressure, associated with the saturated water-gas ratio ("WGR") or Rw, the saturated condensate-gas ratio ("CGR") or Rv, the gas formation volume factor, and the gas viscosity for the corresponding pressure for the stated saturated RWS. For a given PRESS the variability of the gas formation volume factor and the gas viscosity with respect to the under-saturated Rw and Rv is optionally included as a sub table under RWU, RVU, FVFU and VISU columns, that is it is not necessary to repeat PRESS for each sub table entry. However, each sub table must be terminated by a "/". The under saturated Rw and Rv entries are optional, except for perhaps the last PRESS entry to define the PVT properties above the initial saturation pressure.			
			psia	barsa	atma	None
2	RWS	RWU	A columnar vector of real positive numbers for both the saturated (RWS) and under saturated (RWU) Rw sub table entries. The RWS entry on the main table is the saturated WGR at the pressure indicated by PRESS and may be increasing or decreasing in value as PRESS varies. Subsequent under-saturated Rw for a sub table at the given PRESS, as defined by RWU, are monotonically decreasing for entries in a given sub table.			None

[225] *Natural gas that contains significant heavy hydrocarbons such as propane, butane and other liquid hydrocarbons is known as wet gas or rich gas. The general rule of thumb is if the gas contains less methane (typically less than 85% methane) and more ethane, and other more complex hydrocarbons, it is labeled as wet gas. Wet gas normally has GOR's less than 100,000 scf/stb or 18,000 Sm3/m3, with the condensate having a gravity greater than 50 oAPI.*

No.	Name		Description			Default
			Field	Metric	Laboratory	
			stb/Mscf	sm^3/sm^3	rcc/scc	
3	RVS	RVU	A columnar vector of real positive numbers for both the saturated (RVS) and under saturated (RVU) Rv sub table entries. The RVS entry on the main table is the saturated CGR at the pressure indicated by PRESS and may be increasing or decreasing in value as PRESS varies. Subsequent under-saturated Rv for a sub table at the given PRESS, as defined by RVU, are monotonically decreasing for entries in a given sub table.			
			stb/Mscf	sm^3/sm^3	rcc/scc	None
4	FVFS	FVFU	A columnar vector of real decreasing down the column values that defines the corresponding gas phase formation volume factor for a given pressure (PRESS) and for a given Rw (either RWS or RWU) and Rv (either RVS or RVU).			
			rb/Mscf	rm^3/sm^3	rcc/scc	None
5	VISS	VISU	VISS a columnar vector of real increasing down the column values that defines the corresponding gas phase viscosity for a given pressure (PRESS) and for a given RWS and RVS. VISU a columnar vector of real decreasing from VISS down the column values that defines the corresponding gas phase viscosity for a given pressure (PRESS) and for a given RWU and RVU.			
			cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows and NRPVT Rw entries as declared on the TABDIMS keyword in the RUNSPEC section.
3) Apart from the PRES data there must be same number of entries for each column.
4) Each sub table defining the under saturated gas properties must be terminated by "/".
5) Each main table is terminated by a single "/" on a separate line and there is no "/" terminator for the keyword.

Table 8.119: PVTGWO Keyword Description

See also the PVTG keyword in the PROPS section that defines the wet gas PVT properties when vaporized oil is present in the gas phase, and the PVTGW keyword in the PROPS section that defines the dry gas PVT properties when vaporized water is present in the gas phase. As an alternative to using the PVTGWO keyword, the PVTGW and PVTG keywords may be combined to fully define the wet gas PVT properties if both vaporized water and vaporized oil are present in the gas phase.

Example

                                                                 / TABLE NO. 2
```

The above example defines two wet PVT tables assuming NTPVT equals two and NPPVT is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section.

Notice that there is no terminating "/" for this keyword only for a table and a sub table.

8.3.232 PVTO - OIL PVT PROPERTIES FOR LIVE OIL

Description

PVTO defines the oil PVT properties for live oil[226] and the keyword should only be used if the there is both oil and gas phases in the model. This keyword should be used when the DISGAS keyword has be declared in the RUNSPEC section indicating that dissolved gas (more commonly referred to as solution gas) is present in the oil. The keyword may be used for oil-water and oil-water-gas input decks.

No.	Name		Description			Default
			Field	Metric	Laboratory	
1	RS		A real monotonically increasing down the column values that defines the saturated gas-oil ratio ("GOR") or Rs, that defines the oil formation volume factor and the oil viscosity for the tabulated corresponding pressure for stated saturated RS. For a given RS the variability of the oil formation volume factor and the oil viscosity with respect to the saturated RS and pressure is optionally included as a sub table under PRSU, FVFU and VISU columns, that is it is not necessary to repeat RS for each sub table entry. However, each sub table must be terminated by a "/". The under-saturated PRSU entries are optional, except for perhaps the last RS entry to define the PVT properties above the initial saturation pressure. If there are no following under-saturated PRSU entries then the RS entry row should be terminated by a "/", if there are under-saturated PRSU entries then the last PRSU entry row should be terminated by a "/".			
			Mscf/stb	sm^3/sm^3	scc/scc	None
2	PRSS	PRSU	PRSS is a real columnar vector of real monotonically increasing down the column values that defines the oil phase saturation pressure (bubble-point pressure), that defines the oil formation volume factor and the oil viscosity for the corresponding PRSS pressure for a given saturated RS. PRSU is a real columnar vector of real monotonically increasing down the column values that defines the oil phase under-saturated pressure that defines the oil formation volume factor and the oil viscosity for the corresponding PRSU pressure for a given saturated RS. Note that PRSU should be greater than PRSS.			
			psia	barsa	atma	None
3	FVFS	FVFU	FVFS is a columnar vector of real increasing down the column values that defines the corresponding oil phase saturated formation volume factor for a given pressure (PRSS) and for a given RS. FVFU is a columnar vector of real decreasing down the column values that defines the corresponding oil phase under-saturated formation volume factor for a given pressure (PRSU) and for a given RS.			
			rb/stb	rm^3/sm^3	rcc/scc	None

[226] *"Live" oil is oil that contains gas in solution, which is normally the case for most conventional oil reservoirs. However, for oil reservoirs classified as heavy oil reservoirs, the in situ dissolved gas may be negligible and oil would then be classified as gas-free oil which is commonly referred to as "dead" oil.*

No.	Name		Description			Default
			Field	Metric	Laboratory	
4	VISS	VISU	VISS a columnar vector of real increasing down the column values that defines the corresponding oil phase saturated viscosity for a given pressure (PRSS) and for a given RS. If this is the only entry for a given RS and PRSS then the record should be terminate by a "/". VISU a columnar vector of real decreasing from VISS down the column values that defines the corresponding oil phase under-saturated viscosity for a given pressure (PRSU) and for a given RS. If this is the only entry for a given RS and PRSU then the record should be terminate by a "/".			
			cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows and NRPVT Rs entries as declared on the TABDIMS keyword in the RUNSPEC section.
3) Apart from the RS data there must be same number of entries for each column.
4) Each sub table defining the under saturated oil properties must be terminated by "/".
5) Each main table is terminated by a single "/" on a separate line and there is no "/" terminator for the keyword.

Table 8.120: PVTO Keyword Description

Note that provided the first table has been entered, subsequent tables may be defaulted, in this case the prior table is copied to the current table. See the second example for an illustration on how to use this feature.

Example

The first example defines live oil PVT tables assuming NTPVT equals two, NPPVT is greater than or equal to two, and NRPVT is greater than or equal to 18 on the TABDIMS keyword in the RUNSPEC section.

          0.9330    3500.0    1.48790   0.4020  /
          1.0140    3750.0    1.52980   0.3840  /
          1.0960    4000.0    1.57280   0.3680  /
          1.1800    4258.0    1.61760   0.3530  /
          1.2630    4500.0    1.66190   0.3400  /
          1.3480    4750.0    1.70780   0.3280  /
          1.4340    5000.0    1.75480   0.3170  /
          1.6060    5500.0    1.85020   0.2980
                    6242.0    1.83040   0.3186  /
                                                / TABLE NO. 2
```

Notice that there must be at least two entries for the last Rs value to enable the simulator to interpolate over the undersaturated pressure region.

The second example defines live oil PVT tables assuming NTPVT equals four, NPPVT is greater than or equal to two, and NRPVT is greater than or equal to 13 on the TABDIMS keyword in the RUNSPEC section. Here, tables two to four all default to table number one.

```

                                                 / TABLE NO. 4
```

Again, note that there is no terminating "/" for this keyword only for a table and a sub table.

8.3.233 PVTSOL - OIL PVT PROPERTIES FOR LIVE OIL VERSUS CO2 MASS FRACTION

Description

PVTSOL defines the live oil PVT properties as a function of CO_2 mass fraction. The keyword automatically invokes the simulator's CO2 Dynamic EOR Model[227], that uses a fourth component to model the injected CO_2., for use in evaluating CO_2 Enhanced Oil Recovery ("EOR") projects. Normally CO_2 EOR projects are evaluated via compositional simulators to account for the mass transfer of the various components and phases. Unfortunately, compositional models are computationally expensive compared to the black-oil approach, which for field studies is challenging, especially if an ensemble approach is being used to capture the uncertainties. Previous extended black-oil formulations often poorly represent the PVT properties of the oil-CO_2 mixtures, resulting in poor agreement with the compositional formulation.

To overcome the limitations of the standard four component black-oil formulation, OPM Flow uses an improved extended black-oil formulation, the CO2 Dynamic EOR Model, with the black-oil properties dependent on the fraction of CO2 in the cell, as described by the PVTSOL keyword. This approach models the oil-CO2 mixture more accurately and thus give results closer to the compositional simulator. Data for the keyword should normally be derived from laboratory or numerical slim-tube experiments based on one-dimensional compositional Equation Of State ("EOS") simulations.

Note, if this keyword is absent from the input deck then the CO2 Standard EOR Model is used instead.

No.	Name		Description			Default
			Field	Metric	Laboratory	
1	CO2		A real monotonically increasing down the column values that stipulates the CO2 mass fraction, that defines the oil and gas properties, formation volume factor, viscosity etc., for the tabulated corresponding pressure for the stated CO2 mass fraction. CO2 should be greater than or equal to zero and less than or equal to one. Note it is not necessary to repeat the value of CO2 for the pressure column. However, for a given CO2 mass fraction, the last pressure entry (PRESS) of the sub table should be terminated by a "/".			
			dimensionless	dimensionless	dimensionless	None
2		PRESS	PRESS is a real columnar vector of real monotonically increasing down the column values that defines the oil phase saturation pressure (bubble-point pressure), that defines the oil formation volume factor and the oil viscosity for the corresponding PRESS pressure for a given saturated value of CO2.			
			psia	barsa	atma	None
3		OFVF	OFVF is a columnar vector of real increasing down the column values that defines the corresponding oil phase saturated formation volume factor for a given pressure (PRESS) and for a given saturated value of CO2.			
			rb/stb	rm^3/sm^3	rcc/scc	None

[227] *T. H. Sandve, O. Sævareid and I. Aavatsmark: "Improved Extended Blackoil Formulation -- for CO2 EOR Simulations." in ECMOR XVII – The 17th European Conference on the -- Mathematics of Oil Recovery, September 2020.*

No.	Name		Description			Default
			Field	Metric	Laboratory	
4		GFVF	GFVF is a columnar vector of real decreasing down the column values that defines the corresponding gas phase saturated formation volume factor for a given pressure (PRESS) and for a given saturated value of CO2.			
			rb/Mscf	rm^3/sm^3	rcc/scc	None
5		RS	RS is a real monotonically increasing down the column values that defines the saturated gas-oil ratio ("GOR") or Rs, for the given value of PRESS and for a given saturated value of CO2.			
			Mscf/stb	sm^3/sm^3	scc/scc	None
6		RV	RV is a real monotonically increasing down the column values that defines the saturated condensate-gas ratio ("CGR") or Rv, for the given value of PRESS and for a given saturated value of CO2.			
			stb/Mscf	sm^3/sm^3	scc/scc	None
7		XVOL	XVOL is a real positive value greater than or equal to zero and less than or equal to one, that stipulates the volumetric fraction of CO2 in the oil phase, that is: $$XVOL = \frac{Volume_{oil}(CO_2)}{Volume_{oil}(CO_2) + Volume_{oil}(Gas) + Volume_{oil}(Oil)}$$ where: Volume $_{oil}$ (CO_2) is the surface volume of CO_2 in the oil phase, Volume oil (Gas) is the surface volume of gas in the oil phase, and Volume $_{oil}$ (Oil) is the surface volume of oil in the oil phase.			
			dimensionless	dimensionless	dimensionless	None
8		YVOL	YVOL is a real positive value greater than or equal to zero and less than or equal to one, that defines the volumetric fraction of CO2 in the gas phase, that is: $$YVOL = \frac{Volume_{gas}(CO_2)}{Volume_{gas}(CO_2) + Volume_{gas}(Gas) + Volume_{gas}(Oil)}$$ where: Volume $_{gas}$ (CO_2) is the surface volume of CO_2 in the gas phase, Volume $_{gas}$ (Gas) is the surface volume of gas in the gas phase, and Volume gas (Oil) is the surface volume of oil in the gas phase.			
			dimensionless	dimensionless	dimensionless	None
9		OVISC	OVISC is a columnar vector of real decreasing down the column values that defines the corresponding oil phase saturated viscosity for a given pressure (PRESS) and for a given saturated value of CO2.			
			cP	cP	cP	None

No.	Name		Description			Default
			Field	Metric	Laboratory	
10		GVISC	GVISC is a columnar vector of real increasing down the column values that defines the corresponding gas phase saturated viscosity for a given pressure (PRESS) and for a given saturated value of CO2.			
			cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows and NRPVT Rs entries as declared on the TABDIMS keyword in the RUNSPEC section.
3) Except for the CO2 column, there must be same number of entries for each column.
4) Each sub table defining the properties for a given value of CO2 must be terminated by "/" and the keyword itself is terminated by "/".

Table 8.121: PVTSOL Keyword Description

See also the PVDS keyword in the PROPS section that can also be used to model CO2 injection, using the SOLVENT model (CO2 Standard EOR), this is the conventional approach, and does not take into account black-oil properties being dependent on the fraction of CO2.

Note

In the CO2 Dynamic EOR Model the oil properties within a cell are dependent on the CO2 saturation in the cell. However, the model is not restricted to just CO2 utilization, as long as the appropriate oil-injection-gas dependent properties are entered in the model via the PVTSOL keyword.

Thus, N2 or other miscible gases may be used instead of CO2, provided due care is taken in generating the required data for the PVTSOL keyword.

Another example would be a gas-condensate re-cycling project where the produced gas is stripped of the liquids and then re-injected back into the reservoir in order to maintain the reservoir pressure. Here, the CO2 fraction in the PVTSOL keyword would be replaced by the lean injected gas fraction. Again the other properties would be derived from laboratory or numerical slim-tube experiments based on one-dimensional compositional EOS simulations.

As an aside, the scope and accuracy of gas condensate modeling using black-oil reservoir simulators is well established in the industry; both depletion and gas cycling above the dew point can be modeled and yield an adequate match with the results from multi-component compositional simulators. The main inadequacy is with the treatment of gas injection below the dew point where the primary compositional effect, the stripping of liquid components is inversely proportional to their molecular weights, is completely ignored. The standard black-oil model assumes that the saturated hydrocarbon fluid properties are functions of pressure only and disregards any compositional dependence in the saturated fluid PVT properties. Thus, when dry gas is injected into a condensate below its dew point the gas continues to re-vaporize liquid at a rate governed only by the ambient pressure. The vapor saturates over a zone whose thickness is of the order of one grid block; in particular all the liquid in the vicinity of the injectors evaporates rapidly. Results obtained with fully compositional simulation models suggest that liquid saturation profiles would vary more slowly with increasing distance from the gas injectors. This compositional effect can thus be modeled via the CO2 Dynamic EOR Model, although there are no test cases at this stage.

The above example defines one oil PVT Properties for Live Oil versus CO2 Mass Fraction table, and assumes that NTPVT equals one the TABDIMS keyword in the RUNSPEC section.

8.3.234 PVTW - DEFINE WATER FLUID PROPERTIES FOR VARIOUS REGIONS

Description

PVTW defines the water properties for various regions in the model. The number of PVTW vector data sets is defined by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section and the allocation of the PVTW tables to different grid blocks in the model is done via the PVTNUM keyword in the REGIONS section. One data set consists of one record or line which is terminated by a "/". If the water phase is active in the model, which is normally the case, then this keyword must be defined in the OPM Flow input deck.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRES	PRES is a real number defining the water reference pressure (P) for the other parameters for this data set.			
		psia	barsa	atma	None
2	WFVF	WFVF is a real number defining the water formation volume factor (Bw) at the water reference pressure.			
		rb/stb 1.0	rm^3/sm^3 1.0	rcc/scc 1.0	Defined
3	WCOMP	WCOMP is a real number defining the water compressibility (Cw) at the water reference pressure and is defined as: $$C_w = -\frac{1}{B_w}\left(\frac{dB_w}{dP}\right)$$			
		1/psia 0.00004	1/barsa 0.00004	1/atma 0.00004	Defined
4	WVISC	WVISC is a real number defining the water viscosity (μw) at the water reference pressure.			
		cP 0.50	cP 0.50	cP 0.50	Defined
5	WVISCOMP	WVISCOMP is a real number defining the water viscosibility (μwc) at the water reference pressure, μwc(Pref) and is defined as: $$\mu_{wc} = -\frac{1}{\mu_w}\left(\frac{d\mu_w}{dP}\right)$$			
		1/psia 0.0	1/barsa 0.0	1/atma 0.0	Defined

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.122: PVTW Keyword Description

Note that provided the first table has been entered, subsequent tables may be defaulted, in this case the prior table is copied to the current table. See the third example for an illustration on how to use this feature.

Examples

The following shows the PVTW keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to one.

```
--
--        WATER PVT TABLE
--
PVTW
--        REF PRES  BW         CW        VISC     VISC
--        PSIA      RB/STB     1/PSIA    CPOISE   GRAD
--        --------  --------   -------   ------   ------
          4840.0    1.019      2.7E-6    0.370    1*          / TABLE NO. 01
```

The next example shows the PVTW keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to three.

```
--
--        WATER PVT TABLE
--
PVTW
--        REF PRES  BW         CW        VISC     VISC
--        PSIA      RB/STB     1/PSIA    CPOISE   GRAD
--        --------  --------   -------   ------   ------
          4640.0    1.008      2.5E-6    0.350    1*          / TABLE NO. 01
          4840.0    1.019      2.7E-6    0.370    1*          / TABLE NO. 02
          4940.0    1.030      2.8E-6    0.390    1*          / TABLE NO. 03
```

The above example defines three water PVT tables and assumes that NTPVT equals three on the TABDIMS keyword in the RUNSPEC section.

The third, and final example, shows the PVTW keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to four. Here table two defaults to table one, and table four defaults to table three

```
--
--        WATER PVT TABLE
--
PVTW
--        REF PRES  BW         CW        VISC     VISC
--        PSIA      RB/STB     1/PSIA    CPOISE   GRAD
--        --------  --------   -------   ------   ------
          4640.0    1.008      2.5E-6    0.350    1*          / TABLE NO. 01
                                                              / TABLE NO. 02
          4940.0    1.030      2.8E-6    0.390    1*          / TABLE NO. 03
                                                              / TABLE NO. 04
```

Note that there is no terminating "/" for this keyword.

8.3.235 PVTWSALT - DEFINE BRINE WATER FLUID PROPERTIES FOR VARIOUS REGIONS

Description

PVTWSALT defines the brine water properties for various regions in the model, for when the brine phase has been activated by the BRINE keyword in the RUNSPEC section. In this case PVTWSALT is used instead of PVTW in the input file. However, if the ECLMC keyword has been entered in the RUNSPEC section to invoke the Multi-Component Brine model, the PVTW keyword should be used instead of PVTWSALT, as with this combination the salinity effect on the density is ignored.

The number of PVTWSALT table data sets is defined by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section and the allocation of the PVTWSALT tables to different grid blocks in the model is done via the PVTNUM keyword in the REGION section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1-1	PRESS	Single real positive value that defines the reference pressure for the data in the following records (Pref). PRESS should be approximately equal to the average reservoir pressures in the model. The simulator uses the previous time step values to forecast the current time step water properties by linear interpolation. If PRESS is not representative of the average reservoir pressures in the model then the linear interpolation might result in nonphysical values of the water saturation and water viscosity.			
		psia	barsa	atma	None
1-2	SALTSURF	A real value that defines the reference salt concentration in the solution in the surface stock tank water (Cs, ref) If defaulted SALTSURF is taken as the minimum salt concentration entered in the SALTCON columnar vector in the second record for this keyword. This should be in most cases be zero.			
		lb/stb	kg/sm^3	gm/scc	Defined
1-3	/	Record terminated by a "/"			Not Applicable
2-1	SALTCON	A columnar vector of real monotonically increasing values that defines the salt concentration in the solution (Cs).			
		lb/stb	kg/sm^3	gm/scc	None
2-2	WFVF	WFVF is a real columnar vector defining the water formation volume factor (Bw) at the reference pressure PRESS, for the corresponding salt concentration SALTCON.			
		rb/stb	rm^3/sm^3	rcc/scc	None

No.	Name	Description			Default
		Field	Metric	Laboratory	
2-3	WCOMP	WCOMP is a real columnar vector defining the water compressibility (Cw) at the water reference pressure PRESS, for the corresponding salt concentration SALTCON. The water compressibility is defined as: $$C_w = -\frac{1}{B_w}\left(\frac{dB_w}{dP}\right)$$			
		1/psia	1/bars	1/atma	None
2.4	WVISC	WVISC is a real columnar vector defining the water viscosity (μw) at the water reference pressure PRESS, for the corresponding salt concentration SALTCON.			
		cP	cP	cP	None
2.5	WVISCOMP	WVISCOMP is a real columnar vector defining the water viscosibility (μwc) at the water reference pressure PRESS, for the corresponding salt concentration SALTCON. The water viscosibility is defined as: $$\mu_{wc} = -\frac{1}{\mu_w}\left(\frac{d\mu_w}{dP}\right)$$			
		1/psia	1/barsa	1/atma	None
2-6	/	Table and record terminated by a "/"			Not Applicable

Notes:

1) The keyword is followed by NTPVT data sets as declared on the TABDIMS keyword in the RUNSPEC section and each data set consists of two records, with items 1-1 to 1-3 representing record one items and 2-1 to 2-6 representing record number two items, etc., in the "No." column in this table.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.123: PVTWSALT Keyword Description

As mentioned above, the simulator first calculates the water properties as functions of the salt concentration at the previous time step by linear interpolation in salt concentration for water compressibility (Cw), water viscosibility (μwc), $\frac{1}{B_w}$ and $\frac{1}{B_w\ \mu_w}$. It then calculates the values of B_w and $B_w\ \mu_w$ at the current time step using the current pressure P, using the following equations:

$$B_w(P,C_s) = \frac{B_w(P_{ref},C_{s,ref})}{1 + C_w(P-P_{ref}) + \frac{(C_w(P-P_{ref}))^2}{2}} \quad (8.86)$$

and

$$B_w(P,C_s)\ \mu_w(P,C_s) = \frac{B_w(P_{ref},C_{s,ref})\ \mu_w(P_{ref},C_{s,ref})}{1 + (C_w - \mu_{wc})(P-P_{ref}) + \frac{((C_w - \mu_{wc})(P-P_{ref}))^2}{2}} \quad (8.87)$$

See also the BDENSITY keyword in the PROPS section that defines the brine surface densities for the salt concentrations declared on the PVTWSALT keyword. Note that if the BDENSITY keyword is absent from the input file then the brine surface densities will be set to the water density values declared via the DENSITY keyword in the PROPS section. In this case there is no variation in brine surface density with respect to salt concentration.

Example

The following shows the PVTWSALT keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set equal to two and NPPVT is set to greater than four on the TABDIMS keyword.

```
--
--        WATER SALT PVT TABLE
--
PVTWSALT
--        REF PRES  REF SALT
--        PSIA      LB/STB
--        --------  --------
          4500.0    0.000                                  / TABLE NO. REF. DATA

```

Note that each table is terminated by a "/" and there is no "/" terminator for the keyword.

8.3.236 PYEND – END THE DEFINITION OF A PYINPUT SECTION

The PYINPUT and PYEND keywords are a part of OPM Flow's Python scripting facility that processes standard Python commands that can be used to manipulate and define the simulators input parameters during processing of the input deck. The main purpose of the facility is to script the construction of the various keywords. A PYINPUT Definition Section is terminated by a PYEND keyword on a separate single line.

See *PYEND – End the Definition of a PYINPUT Section* in the GRID section for a full description.

8.3.237 PYINPUT – DEFINE THE START OF A PYINPUT SECTION

The PYINPUT and PYEND keywords are a part of OPM Flow's Python scripting facility that processes standard Python commands that can be used to manipulate and define the simulators input parameters during processing of the input deck. The main purpose of the facility is to script the construction of the various keywords used by the simulator. PYINPUT declares the start of a PYINPUT Definition Section on a single separate line, which is then followed by various standard Python commands, with one command per line.

See *PYINPUT – Define the Start of a PYINPUT Section* in the GRID section for a full description.

8.3.238 PVZG - GAS PVT PROPERTIES FOR DRY GAS (Z-FACTOR)

Description

PVZG defines the gas PVT properties for dry gas[228] via the gas compressibility factor (z-factor), instead of the gas formation volume factor. If the gas has a constant and uniform vaporized oil concentration, Condensate-Gas Ratio ("CGR"), and if the reservoir pressure never drops below the saturation pressure (dew point pressure), then the model can be run more efficiently by omitting the OIL and VAPOIL keywords from the RUNSPEC section, treating the gas as a dry gas, and defining a constant Rv (CGR) value with keyword RVCONST or RVCONSTT in the PROPS section. This results in the model being run with as a dry gas problem with no active oil (condensate) phase. However, OPM Flow takes into account the constant Rv in the calculations and reporting.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[228] *Natural gas that occurs in the absence of condensate or liquid hydrocarbons, or gas that had condensable hydrocarbons removed, is called dry gas. It is primarily methane with some intermediates. The hydrocarbon mixture is solely gas in the reservoir and there is no liquid (condensate surface liquid) formed either in the reservoir or at surface. The term dry indicates that the gas does not contain heavier hydrocarbons to form liquids at the surface conditions. Dry gas typically has GOR's greater than 100,000 scf/stb or 18,000 Sm3/m3.*

No.	Name	Description			Default
		Field	Metric	Laboratory	
1-1	RTEMP	Single real positive value that defines the reservoir temperature for the data in the following records.			
		°F	°C	°C	
1-2	/	Record terminated by a "/"			Not Applicable
2-1	PRESS	A columnar vector of real monotonically increasing down the column values that defines the gas phase pressure.			
		psia	barsa	atma	None
2-2	GZFAC	A columnar vector of real values that defines the corresponding gas phase z-factor at the given pressure, PRESS.			
		dimensionless	dimensionless	dimensionless	None
2-3	GVISC	A columnar vector of real increasing down the column values that defines the corresponding gas phase viscosity.			
		cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT data sets as declared on the TABDIMS keyword in the RUNSPEC section and each data set consists of two records, with items 1-1 to 1-2 representing record one items and 2-1 to 2-3 representing record number two items, etc., in the "No." column in this table.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.124: PVZG Keyword Description

See also the RVCONST and RVCONSTT keywords to define the constant Rv for dry gas.

The ideal gas law provides a relationship between the pressure, the temperature and the specific volume of an ideal gas (pure component). This relationship is modified by use of a compressibility factor, Z[229], to account for deviations, from ideal, to the behavior of real gases. The PVT relation for a real gas can be defined by:

$$PV = ZnRT \tag{8.88}$$

As the gas formation volume factor is used to relate the volume of gas, as measured at reservoir conditions, to the volume of gas as measured at standard conditions (60 °F and 14.7 psia, or 15 °C and 101.325 kPa). This gas property is then defined as the actual volume occupied by a certain amount of gas at a specified pressure and temperature, divided by the same amount of gas at standard conditions. Thus, using the above equation one can obtain the gas volumes at reservoir and standard conditions, i.e.

$$V_{sc} = \frac{Z_{sc} nRT_{sc}}{P_{sc}} \tag{8.89}$$

[229] *Standing, M. B.:" Volumetric and Phase Behaviour of Oil Field Hydrocarbon Systems", Renihold Publishing Corp., New York City (1952).*

$$V_i = \frac{Z_i n R T_i}{P_i} \tag{8.90}$$

Thus the gas formation volume factor can be expressed as:

$$E = \frac{V_{sc}}{V_i} \tag{8.91}$$

And substituting equation (8.89) and (8.90) into (8.91) we obtain

$$E = \left(\frac{P_i}{P_{sc}}\right)\left(\frac{T_{sc}}{T_i}\right)\left(\frac{1}{Z_i}\right) \tag{8.92}$$

Incorporating standard pressure and temperature values gives in SI units:

$$E = \left(\frac{P_i}{101.325}\right)\left(\frac{273.15 + 15}{T_i}\right)\left(\frac{1}{Z_i}\right) = 2.84\left(\frac{P_i}{Z_i T_i}\right) \tag{8.93}$$

or in field units:

$$E = \left(\frac{P_i}{14.7}\right)\left(\frac{460 + 60}{T_i}\right)\left(\frac{1}{Z_i}\right) = 35.37\left(\frac{P_i}{Z_i T_i}\right) \tag{8.94}$$

Where,

E	= gas formation volume factor (scf /rcft or Sm^3/m^3)
P	= pressure (psia or kPa)
Psc	= pressure standard conditions (psia or kPa)
Pi	= initial reservoir pressure (psia or kPa)
V	= volume (ft^3 or m^3)
T	= absolute temperature (°R or K)
Tsc	= temperature at standard conditions (°R or K)
Ti	= initial reservoir temperature (°R or K)
R	= gas constant (10.73 or 8.314)

RTEMP on this keyword is the Ti in the above equations and P_i is PRESS columnar vector.

Example

         2500.0    0.857800     0.0181
         2750.0    0.860430     0.0189
         3000.0    0.866440     0.0197
         3250.0    0.874980     0.0206
         3500.0    0.885470     0.0214
         3750.0    0.898350     0.0223
         4000.0    1.025120     0.0277                    / TABLE NO 01
```

The above example defines two dry PVZG tables assuming NTPVT equals two and NPPVT is greater than or equal to 17 on the TABDIMS keyword in the RUNSPEC section. There is no terminating "/" for this keyword.

8.3.239 QHRATING – DEFINE RIVER MASS FLOW VERSUS DEPTH TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The QHRATING keyword defines a river's mass flow rate versus depth tables, for when the River option has been activated via the RIVRDIMS keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.240 REFINE – START THE DEFINITION OF A LOCAL GRID REFINEMENT

The REFINE keyword defines the start of a Cartesian or radial local grid refinement ("LGR") definition that sets the properties of the selected LGR. The keyword is then followed by the property keywords associated with the section where the keyword is being invoked. For example, if the REFINE keyword is used in the GRID section then most of the keywords in that section can be used to set the grid properties for the LGR.

See *REFINE – Start the Definition of a Local Grid Refinement* in the GRID section for a full description.

8.3.241 RIVRXSEC – DEFINE RIVER CROSS-SECTION VERSUS DEPTH PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The RIVRXSEC keyword defines a river's cross-sectional area and perimeter versus depth parameters. The River option must be activated via the RIVRDIMS keyword in the RUNSPEC section in order to use this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.242 RKTRMDIR - ACTIVATE ROCKTAB KEYWORD DIRECTIONAL TRANSMISSIBILITY MULTIPLIERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates the directional transmissibility multipliers for the ROCKTAB keyword. This results in two additional columns being inputted on the ROCKTAB keyword. This feature is currently not supported in OPM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.243 ROCK - DEFINE THE ROCK COMPRESSIBILITY FOR VARIOUS REGIONS

Description

ROCK defines the rock compressibility for various regions in the model. The number of ROCK vector data sets is defined by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section and the allocation of the ROCK tables to different grid blocks in the model is done via the PVTNUM keyword in the REGIONS section. One data set consists of one record or line which is terminated by a "/".

This keyword must be defined in the OPM Flow input deck.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	PRESS is a real number defining the rock reference pressure for the other parameters for this data set.			
		psia 14.7	barsa 1.0132	atma 1.0	Default
2	RCOMP	RCOMP is a real number defining the rock compressibility (cf) at the rock reference pressure and is defined as: $c_f = -\frac{1}{V}\left(\frac{dV}{dP}\right)$			
		1/psia 0.0	1/barsa 0.0	1/atma 0.0	Defined

Notes:

1) The keyword is followed by NTPVT vectors as declared by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section.

   Note, however, that if ROCKOPTS(ROCKOPT3) parameter has been used to set the allocation of the ROCK data via the ROCKNUM array, then the number of ROCK vectors should correspond to the value entered on TABDIMS(NTROCC) in the RUNSPEC section. Similarly, if the ROCKOPTS(ROCKOPT3) has been used to set the assignment of the ROCK data via the SATNUM array, then the number of vectors should correspond to the value entered via the TABDIMS(NTSFUN) parameter, since the tables will be allocated via the SATNUM array.

2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.125: ROCK Keyword Description

The simulator adjusts the pore volume based on the reference pressure (PRESS), that is:

$$V(P_i) = V(P_r)\left(1 + c_f(P_i - P_r) + \frac{\left(c_f(P_i - P_r)\right)^2}{2}\right) \quad (8.95)$$

where:

c_f = rock compressibility (RCOMP) at the reference pressure (PRESS),
P_i = initial grid cell pressure,
P_r = reference pressure (PRESS),
$V(P_i)$ = pore volume at initial conditions, and
$V(P_r)$ = pore volume at at the reference pressure.

Note

If the Rock Compaction option has been activated via the ROCKCOMP keyword in the RUNSPEC section, then the ROCKTAB keyword in the PROPS section should be used instead of ROCK keyword.

See also the ROCKOPTS and ROCKTAB keywords in the PROPS section.

Examples

The following shows the ROCK keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to one.

```
--
--       ROCK COMPRESSIBILITY
--
--       REFERENCE PRESSURE IS TAKEN FROM THE HCPV WEIGHTED RESERVOIR PRESSURE
--       AS THE PORV IS ALREADY AT RESERVOIR CONDITIONS (OPM FLOW USES THE
--       REFERENCE PRESSURE) TO CONVERT THE GIVEN PORV TO RESERVOIR CONDITIONS
--       USING THE DATA ON THE ROCK KEYWORD)
--
--       REF PRES  CF
--       PSIA      1/PSIA
--       --------  --------
ROCK
         3966.9    5.0E-06                                  / ROCK COMPRESSIBILITY
```

The next example shows the ROCK keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to three.

```
--
--       ROCK COMPRESSIBILITY
--
--       REFERENCE PRESSURE IS TAKEN FROM THE HCPV WEIGHTED RESERVOIR PRESSURE
--       AS THE PORV IS ALREADY AT RESERVOIR CONDITIONS (OPM FLOW USES THE
--       REFERENCE PRESSURE) TO CONVERT THE GIVEN PORV TO RESERVOIR CONDITIONS
--       USING THE DATA ON THE ROCK KEYWORD)
--
--       REF PRES  CF
--       PSIA      1/PSIA
--       --------  --------
ROCK
         3566.9    5.0E-06                       / ROCK COMPRESSIBILITY REGION 1
         3966.9    5.5E-06                       / ROCK COMPRESSIBILITY REGION 2
         4566.9    6.0E-06                       / ROCK COMPRESSIBILITY REGION 3
```

The above example defines three ROCK tables and assumes that NTPVT equals three on the TABDIMS keyword in the RUNSPEC section.

There is no terminating "/" for this keyword, and thus the number entries must match the value entered via the TABDIMS(NTPVT), TABDIMS(NTROCC), or TABDIMS(NTSFUN) parameters, depending on the option selected via the ROCKOPTS keyword.

8.3.244 ROCK2D – PORE VOLUME COMPACTION VERSUS PRESSURE AND SW TABLES

Description

The ROCK2D keyword defines rock compressibility pore volume multipliers as a function of pressure and water saturation ("Sw") for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section. The pressure values are defined on this keyword and the water saturations are declared on the associated ROCKWNOD keyword in the PROPS section

The rock compaction pore volume and transmissibility multipliers, entered via the ROCKTAB, ROCK2D and ROCK2DTR keywords, are applied to the pore pressure, unless the OVERBURD keyword in PROPS section is included in the input deck. When the OVERBURD keyword is present the multipliers are applied to the effective pore volume pressure, that is $P_{(effective)} = P_{(Pressure)} - P_{(overburden)}$. If the keyword is not present in the input deck then the overburden pressure is set to zero.

This keyword should only be used if compaction option has been enabled.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A columnar vector of real monotonically increasing down the column values that defines the corresponding overburden pressure for the subsequent MULT columnar vector.			
		psia	bars	atm	None
2	MULT	A columnar vector of real equal or decreasing down the column values that are less than or equal to one, that defines the rock compressibility pore volume multipliers corresponding to PRESS and for each water saturation entry in the ROCKWNOD keyword.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTROCC tables as declared on the ROCKCOMP keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.126: ROCK2D Keyword Description

See also the OVERBURD, ROCKTAB, ROCK2DTR, and ROCKWNOD keywords in the PROPS section.

Example

The following example defines two pore volume compaction tables, assuming NTROCC is equal to two on the ROCKCOMP keyword and NSSFUN is greater than or equal to four on the TABDIMS keyword.

```
--
--       ROCK COMPACTION VERSUS PRESSURE AND SW TABLES
--

--       PRESS    PORV
--       PSIA     MULTIPLER
--       ------   ----------
         1000.0      0.880
                     0.880
                     0.880
                     0.880                              / P-SW SET TABLE NO. 02
--       PRESS    PORV
--       PSIA     MULTIPLER
--       ------   ----------
         2500.0      0.950
                     0.950
                     0.950
                     0.950                              / P-SW SET TABLE NO. 02
--       PRESS    PORV
--       PSIA     MULTIPLER
--       ------   ----------
         5000.0      1.000
                     1.000
                     1.000
                     1.000                              / P-SW SET TABLE NO. 02
```

Note that there must be exactly NTROCC tables entered for this keyword, otherwise an error will occur.

8.3.245 ROCK2DTR – TRANSMISSIBILITY COMPACTION VERSUS PRESSURE AND SW TABLES

Description

The ROCK2DTR keyword defines rock compressibility transmissibility multipliers as a function of pressure and water saturation ("Sw") for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section. The pressure values are defined on this keyword and the water saturations are declared on the associated ROCKWNOD keyword in the PROPS section

The rock compaction pore volume and transmissibility multipliers, entered via the ROCKTAB, ROCK2D and ROCK2DTR keywords, are applied to the pore pressure, unless the OVERBURD keyword in PROPS section is included in the input deck. When the OVERBURD keyword is present the multipliers are applied to the effective pore volume pressure, that is $P_{(effective)} = P_{(Pressure)} - P_{(overburden)}$. If the keyword is not present in the input deck then the overburden pressure is set to zero.

This keyword should only be used if compaction option has been enabled.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A columnar vector of real monotonically increasing down the column values that defines the corresponding overburden pressure for the subsequent MULT columnar vector.			
		psia	bars	atm	None
2	MULT	A columnar vector of real equal or decreasing down the column values that are less than or equal to one, that defines the rock compressibility transmissibility multipliers corresponding to PRESS and for each water saturation entry in the ROCKWNOD keyword.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTROCC tables as declared on the ROCKCOMP keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.127: ROCK2DTR Keyword Description

See also the OVERBURD, ROCKTAB, ROCK2D, and ROCKWNOD keywords in the PROPS section.

Example

The following example defines two rock compressibility transmissibility compaction tables, assuming NTROCC is equal to two on the ROCKCOMP keyword and NSSFUN is greater than or equal to four on the TABDIMS keyword.

```
--
--       TRANSMISSIBILITY COMPACTION VERSUS PRESSURE AND SW TABLES
--

                     0.950
                     0.950
                     0.950                                  / P-SW SET TABLE NO. 02
--       PRESS    TRAN
--       PSIA     MULTIPLER
--       ------   ----------
         5000.0      1.000
                     1.000
                     1.000
                     1.000                                  / P-SW SET TABLE NO. 02
```

Note that there must be exactly NTROCC tables entered for this keyword, otherwise an error will occur.

8.3.246 ROCKOPTS – DEFINE ROCK COMPACTION AND COMPRESSIBILITY OPTIONS

Description

The ROCKOPTS keyword defines various option with respect to rock compaction and rock compressibility.

No.	Name	Description	Default
1	ROCKOPT1	ROCKOPT1 is a character string that defines the treatment of how the overburden pressures supplied by the OVERBURD keyword are applied to the tabulated pressures in the ROCKTAB keywords: 1) STRESS: Use this option if the overburden pressures on the OVERBURD keyword are greater than the fluid pressure which results in the effective fluid pressure being negative. To avoid the rock compaction tables being entered with negative pressure values use this option. In this case the pore volume and transmissibility multipliers will be tabulated against the effective overburden pressure. 2) PRESSURE: In this case the pore volume and transmissibility multipliers should be effective pressure. This the default value. ROCKOPT1 should be set to PRESSURE if the OVERBURD is not used in the input deck. Only the default value of PRESSURE is supported.	PRESSURE
2	ROCKOPT2	ROCKOPT2 is a character string that sets the reference pressure option: 1) STORE: Copies the initial calculated grid block pressures into the overburden pressure array, resulting in the pore volumes being referenced at the initial pressures instead of the reference pressures as per the ROCKTAB keyword. 2) NOSTORE: This option results in the pore volumes being referenced as per the ROCKTAB keyword. This is the default value. Note that STORE option should not be used with the OVERBURD keywords as the OVERBURD data will be overwritten. Only the default value of NOSTORE is supported.	NOSTORE
3	ROCKOPT3	ROCKOPT3 is a character string that defines which region array should be used to allocate the various ROCK and ROCKTAB property tables in the model: 1) ROCKOPT3, should be set to ROCKNUM, SATNUM or PVTNUM. 2) If the parameter is defaulted or the ROCKOPT keyword is not present in the deck, then the PVTNUM array is used. 3) Secondly, if ROCKOPT3 is set to ROCKNUM but the NTROCC parameter on the TABDIMS keyword in the RUNSPEC section is defaulted, then again the PVTNUM array will be utilized. Only the PVTNUM and ROCKNUM options are currently supported.	PVTNUM

No.	Name	Description	Default
4	ROCKOPT4	ROCKOPT4 is a character string that sets the initial conditions for the HYSTER and BOBERG options: 1) DEFLATION: This option defines the reservoir rock to be fully compacted and the deflation curve is used to calculated the initial pore volume and transmissibility multipliers. This is the default value. 2) ELASTIC: This option sets the pore volume and transmissibility multipliers to one, as the reservoir rock is set to lie on the elastic curve. This parameter is ignored by OPM Flow as the ROCKCOMP(ROCKOPT) options of HYSTER and BOBERG are not supported by the simulator.	DEFLATION
Notes: 1) The keyword is terminated by a "/".			

Table 8.128: ROCKOPTS Keyword Description

Example

```
--
--        ROCKOPT1  ROCKOPT2   ROCKOPT3  ROCKOPT3
--        PRS/STRE  NO/STORE   ARRAY
--        --------  --------   --------  --------
ROCKOPTS
          PRESSURE  NOSTORE    PVTNUM                        / ROCK COMP OPTIONS
```

The above example defines the default values for the ROCKOPTS keyword.

8.3.247 ROCKPAMA – DEFINE COAL PALMER-MANSORRI ROCK MODEL PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

ROCKPAMA defines the Palmer-Mansoori[230] and [231] parameters used for this rock model, for when the Coal Bed Methane option has been activated via the COAL keyword, and PALM-MAN has been declared for the ROCKOPT variable on the ROCKCOMP keyword; both keywords are in the RUNSPEC section. The Palmer-Mansoori rock model is used to calculate the impact on pore volume and permeability due to rock compaction.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[230] *Palmer, I. and Mansoori, J. "How Permeability Depends on Stress and Pore Pressure in Coalbeds: A New Model," paper SPE 52607, SPE Reservoir Evaluation & Engineering (1998) 1, No. 6, 539-544.*

[231] *Clarkson, C.R., Pan, Z., Palmer, I. and Harpalani, S. "Predicting Sorption-Induced Strain and Permeability Increase With Depletion for Coalbed-Methane Reservoirs", SPE 114778-PA, SPE Journal (2010) 15, No. 1, 152–159.*

8.3.248 ROCKTAB – ROCK COMPACTION TABLES

Description

The ROCKTAB keyword defines the rock compaction attributes to be applied for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section. ROCKTAB defines pore volume and transmissibility multipliers versus pressure that are used in the compaction calculations. If the RKTRMDIR has been activated in the PROPS section, then the transmissibility multiplier is directional dependent and two additional columns are used to define the y and z direction transmissibility multipliers.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	If the ROCKOPT1 variable has been set to PRESSURE on the ROCKOPTS keyword in the PROPS section, then PRESS should be a columnar vector of real monotonically increasing down the column values, that define the reference pressure for which the other parameters correspond to. If ROCKOPT1 has been set to STRESS, then PRESS should be a columnar vector of real monotonically decreasing down the column values.			
		psia	bars	atm	None
2	PORV	A columnar vector of real positive values that are either equal or increasing down the column that define the rock pore volume multiplier for a given PRESS.			
		dimensionless	dimensionless	dimensionless	None
3	TRANS	If the RKTRMDIR is absent from the input deck, then TRANS is a columnar vector of real positive values that are either equal or increasing down the column that define the x, y, and z directional transmissibility multipliers for the corresponding PRESS. If the RKTRMDIR is present in the input deck, then TRANS is a columnar vector of real positive values that are either equal or increasing down the column that define only the x directional transmissibility multipliers for the corresponding PRESS.			
		dimensionless	dimensionless	dimensionless	None
4	TRANSY	If the RKTRMDIR is absent from the input deck, then TRANSY is ignored. If the RKTRMDIR is present in the input deck, then TRANSY is a columnar vector of real positive values that are either equal or increasing down the column that define only the y directional transmissibility multipliers for the corresponding PRESS.			
		dimensionless	dimensionless	dimensionless	None

No.	Name	Description			Default
		Field	Metric	Laboratory	
5	TRANSZ	If the RKTRMDIR is absent from the input deck, then TRANSZ is ignored. If the RKTRMDIR is present in the input deck, then TRANSZ is a columnar vector of real positive values that are either equal or increasing down the column that define only the z directional transmissibility multipliers for the corresponding PRESS.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTROCC tables as declared on the ROCKCOMP keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.129: ROCKTAB Keyword Description

Examples

The example below defines two rock compaction tables, assuming NTROCC is equal to two on the ROCKCOMP keyword and NPPVT is greater than or equal to five on the TABDIMS keyword and that the RKTRMDIR keyword is present in the input deck.

```
--
--       ROCK COMPACTION TABLES
--
ROCKTAB
--       PRESS    PORV     TX(YZ)   TY       TZ
--                MULT     MULT     MULT     MULT
--       ------   ------   ------   ------   ------

--       ------   ------   ------   ------   ------
         1000.0   0.9600   0.9650   0.9650   0.9650
         1500.0   0.9800   0.9850   0.9850   0.9500
         3000.0   0.9900   0.9950   0.9950   0.9950
         4500.0   1.0000   1.0000   1.0000   1.0000
         4750.0   1.0100   1.0100   1.0100   1.0100        / TABLE NO. 02
```

As the x, y and z directional transmissibility multipliers are identical in the above example, we could eliminate the RKTRMDIR keyword from the input deck and enter the data in the three column format, as shown on the next page.

```
--
--       ROCK COMPACTION TABLES
--
ROCKTAB
--       PRESS    PORV     TX(YZ)
--                MULT     MULT
--       ------   ------   ------
         1000.0   0.9600   0.9650
         1500.0   0.9800   0.9850
         3000.0   0.9900   0.9950
         4500.0   1.0000   1.0000
         4750.0   1.0100   1.0100                          / TABLE NO. 01
--       PRESS    PORV     TX(YZ)
--                MULT     MULT
--       ------   ------   ------
         1000.0   0.9600   0.9650
         1500.0   0.9800   0.9850
         3000.0   0.9900   0.9950
         4500.0   1.0000   1.0000
         4750.0   1.0100   1.0100                          / TABLE NO. 02
```

The net result of the two examples in this case is identical.

8.3.249 ROCKTABH – ROCK COMPACTION HYSTERESIS TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ROCKTABH keyword defines the rock compaction hysteresis attributes to be applied for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section. ROCKTABH defines pore volume and transmissibility multipliers versus pressure that are used in the compaction calculations. If the RKTRMDIR has been activated in the PROPS section, then the transmissibility multiplier is directional dependent and two additional columns are used to define the y and z direction transmissibility multipliers. The keyword should only be used if the Rock Compaction Hysteresis option has been activated by either setting the ROCKOPT parameter on the ROCKCOMP keyword to HYSTER or BOBERG.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	If the ROCKOPT1 variable has been set to PRESSURE on the ROCKOPTS keyword in the PROPS section, then PRESS should be a columnar vector of real monotonically increasing down the column values, that define the reference pressure for which the other parameters correspond to. If ROCKOPT1 has been set to STRESS, then PRESS should be a columnar vector of real monotonically decreasing down the column values.			
		psia	bars	atm	None
2	PORV	A columnar vector of real positive values that are either equal or increasing down the column that define the rock pore volume multiplier for a given PRESS.			
		dimensionless	dimensionless	dimensionless	None
3	TRANS	If the RKTRMDIR is absent from the input deck, then TRANS is a columnar vector of real positive values that are either equal or increasing down the column that define the x, y, and z directional transmissibility multipliers for the corresponding PRESS. If the RKTRMDIR is present in the input deck, then TRANS is a columnar vector of real positive values that are either equal or increasing down the column that define only the x directional transmissibility multipliers for the corresponding PRESS.			
		dimensionless	dimensionless	dimensionless	None
4	TRANSY	If the RKTRMDIR is absent from the input deck, then TRANSY is ignored. If the RKTRMDIR is present in the input deck, then TRANSY is a columnar vector of real positive values that are either equal or increasing down the column that define only the y directional transmissibility multipliers for the corresponding PRESS.			
		dimensionless	dimensionless	dimensionless	None

No.	Name	Description			Default
		Field	Metric	Laboratory	
5	TRANSZ	If the RKTRMDIR is absent from the input deck, then TRANSZ is ignored. If the RKTRMDIR is present in the input deck, then TRANSZ is a columnar vector of real positive values that are either equal or increasing down the column that define only the z directional transmissibility multipliers for the corresponding PRESS.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTROCC tables as declared on the ROCKCOMP keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.130: ROCKTABH Keyword Description

Each data set consists of columnar vectors of pore volume and transmissibility multipliers versus pressure that specify the elastic contraction and expansion and of the reservoir rock. The deflation curve is derived from the first data elements on each elastic curve. If the ROCKOPT parameter on the ROCKCOMP keyword has been set to HYSTER, then the dilation curves are extrapolated to infinite pressure, that is the curves are unbounded. However, if ROCKCOMP is set to BOBERG the last points of each elastic curve are used as the dilation curves.

Example

The example below defines two rock compaction tables, assuming NTROCC is equal to two on the ROCKCOMP keyword and NPPVT is greater than or equal to four on the TABDIMS keyword and that the RKTRMDIR keyword is not present in the input deck.

```
--
--       ROCK COMPACTION HYSTERESIS TABLES
--
ROCKTABH
--       PRESS    PORV     TX(YZ)   TY       TZ
--                MULT     MULT     MULT     MULT
--       ------   ------   ------   ------   ------
         1500.0   0.9600   0.9800
         2500.0   0.9700   0.9850
         3500.0   0.9800   0.9900
         4500.0   0.9900   0.9950                      / NPPVT = 1
         2500.0   0.9900   0.9900
         3500.0   0.9950   0.9950
         4750.0   0.9980   0.9980                      / NPPVT = 2
         3500.0   1.0000   1.0000
         5500.0   1.0100   1.0100                      / NPPVT = 3
         4500.0   1.0100   1.0100
         5750.0   1.0200   1.0200                      / NPPVT = 4

                                                      / TABLE NO. 01
--       PRESS    PORV     TX(YZ)   TY       TZ
--                MULT     MULT     MULT     MULT
--       ------   ------   ------   ------   ------
         1500.0   0.9400   0.9700
         2750.0   0.9400   0.9700                      / NPPVT = 1
         2250.0   0.9800   0.9900
         3250.0   0.9800   0.9900                      / NPPVT = 2
         3000.0   1.0000   1.0000
         4250.0   1.0000   1.0000                      / NPPVT = 3
         4550.0   1.0200   1.0100
         5750.0   1.0200   1.0100                      / NPPVT = 4
                                                      / TABLE NO. 02
```

Here the deflation curve is define for table number one is:

```
         1500.0   0.9600   0.9800
         2500.0   0.9900   0.9900
         3500.0   1.0000   1.0000
         4500.0   1.0100   1.0100
```

and for table number 2:

```
         1500.0   0.9400   0.9700
         2250.0   0.9800   0.9900
         3250.0   1.0000   1.0000
         4250.0   1.0200   1.0100
```

And the dilation curve is define for table number one is:

```
         4500.0   0.9900   0.9950
         4750.0   0.9980   0.9980
         5500.0   1.0100   1.0100
         5750.0   1.0200   1.0200
```

and for table number 2:

```
         2250.0   0.9400   0.9700
         3250.0   0.9800   0.9900
         4250.0   1.0000   1.0000
         5250.0   1.0200   1.0100
```

8.3.250 ROCKTABW – ROCK COMPACTION TABLES (WATER INDUCED)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ROCKTABW keyword defines the rock compaction tables induced by increasing water saturation within a grid cell due to water invasion, for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section. ROCKTABW defines pore volume and transmissibility multipliers versus water saturation that are used in the compaction calculations. The keyword should be used together with the ROCK, ROCKTAB or ROCKTABH keywords that specify the pore volume and transmissibility multipliers as functions of pressure. Alternatively the ROCKWNOD, ROCK2D and ROCK2DTR keywords can be used to enter two dimensional tables of the data. All keywords are in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.251 ROCKTHSG – ROCK COMPACTION HYSTERESIS TABLES (DUAL POROSITY)

Description

The ROCKTHSG keyword defines the rock compaction hysteresis attributes to be applied for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section and the either the Dual Permeability or Dual Porosity models are activated by the DUALPERM and DUALPORO keywords in the RUNSPEC section. ROCKTHSG specifies sigma multipliers versus pressure that are used in the dual porosity rock compaction calculations. The keyword should only be used if the Rock Compaction Hysteresis option has been activated by either setting the ROCKOPT parameter on the ROCKCOMP keyword to one of the available options.

Each data set consists of columnar vectors of sigma multipliers versus pressure that specify the elastic contraction and expansion and of the reservoir rock. The deflation curve is derived from the first data elements on each elastic curve. If the ROCKOPT parameter on the ROCKCOMP keyword has been set to HYSTER, then the dilation curves are extrapolated to infinite pressure, that is the curves are unbounded. However, if ROCKCOMP is set to BOBERG the last points of each elastic curve are used as the dilation curves.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.252 ROCKTSIG – ROCK COMPACTION TABLES (DUAL POROSITY)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ROCKTSIG keyword defines the rock compaction attributes to be applied for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section, and the either the Dual Permeability or Dual Porosity models are activated by the DUALPERM and DUALPORO keywords in the RUNSPEC section. ROCKTSIG specifies sigma multipliers versus pressure that are used in the dual porosity rock compaction calculations. The keyword should only be used if the Rock Compaction Hysteresis option has been activated by either setting the ROCKOPT parameter on the ROCKCOMP keyword to one of the available options.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.253 ROCKWNOD – WATER SATURATION VALUES FOR COMPACTION PRESSURE-SW TABLES

Description

The ROCK2D and the ROCK2DTR keywords in the PROPS section define rock compressibility pore volume and transmissibility multipliers as a function of pressure and water saturation ("Sw"), for when the rock compaction option has been invoked by the ROCKCOMP keyword in the RUNSPEC section. The pressure values are defined on ROCK2D and the ROCK2DTR keywords together with the multipliers. This keyword ROCKWNOD, defines the water saturations that are used in conjunction with the ROCK2D and the ROCK2DTR keywords.

This keyword should only be used if compaction option has been enabled.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWAT	A columnar vector of real monotonically increasing down the column values that defines the water saturations to be associated with the data on the ROCK2D and the ROCKTR keywords.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTROCC tables as declared on the ROCKCOMP keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.131: ROCKWNOD Keyword Description

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

See also the OVERBURD, ROCKTAB, ROCK2D and ROCK2DTR keywords in the PROPS section.

Example

The following example defines two ROCKWNOD tables for the pore volume and transmissibility compaction tables, assuming NTROCC is equal to two on the ROCKCOMP keyword and NSSFUN is greater than or equal to four on the TABDIMS keyword.

```
--
--       WATER SATURATION VALUES FOR COMPACTION PRESSURE-SW TABLES
--
ROCKWNOD
--       COMPACT
--       SWAT
--       ------
          0.000
          0.200
          0.400
          1.000                                          / P-SW SET TABLE NO. 01
--       COMPACT
--       SWAT
--       ------
          0.000
          0.250
          0.750
          1.000                                          / P-SW SET TABLE NO. 02
```

Note that there must be exactly NTROCC tables entered for this keyword, otherwise an error will occur.

8.3.254 RPTPROPS – DEFINE PROPS SECTION REPORTING

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the data in the PROPS section that is to be printed to the output print file in human readable format. The keyword has two distinct forms, the first of which consists of the keyword followed by a series of integers on the next line indicating the data to be printed (see the first example). This is the original formal in the commercial simulator and was subsequently superseded by the second format. The second format consists of the keyword followed by a series of character strings that indicate the data to be printed. In most cases the character string is the keyword used to load the data in the OPM Flow input deck, for example PVDG for the dry gas PVT tables. Its is anticipated that OPM Flow will eventually support the functionality of the second format only, the first format although recognized will be completely ignored.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

No.	Name	Description	Default
1	PVTDG	Print dry gas PVT tables	N/A
2	PVTG	Print wet gas PVT tables	N/A
3	SGFN	Print gas relative permeability saturation function tables.	N/A
4	SGL	Print connate gas saturation array.	N/A
….		….	N/A

Notes:

1) The keyword is terminated by a "/".

Table 8.132: RPTPROPS Keyword Description

Note

Except for tabular like data, PVTDG etc., this keyword has the potential to produce very large print files that some text editors may have difficulty loading. A more efficient solution for array type data is to load the *.INIT file into OPM ResInsight to view the data graphically, this also has the benefit of being able to filter the grid based on I, J, K ranges and grid properties.

Examples

The first example shows the original format of this keyword; although the keyword and format are recognized by OPM Flow, the format is ignored and is unlikely to be implemented in in the simulator.

```
--
--       DEFINE PROPS SECTION REPORT OPTION (ORIGINAL FORMAT)
-
RPTPROPS
         1        2*0      1        3*1                                        /
```

The next example shows the second format of the keyword which may be supported in a future release of OPM Flow.

```
--
--       DEFINE PROPS SECTION REPORT OPTIONS
--
RPTPROPS
         PVDO     SOF2     SGFN     SWFN                                       /
```

8.3.255 RSCONST – DEFINE CONSTANT GOR (RS) FOR ALL DEAD OIL PVT FLUIDS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

RSCONST defines a constant Gas-Oil Ratio ("GOR"), for all dead oil[232] PVT fluids. If the oil has a constant and uniform dissolved gas concentration, GOR, and if the reservoir pressure never drops below the saturation pressure (bubble point pressure), then the model can be run more efficiently by omitting the GAS and DISGAS keywords from the RUNSPEC section, treating the oil as a dead oil, and defining a constant Rs (GOR) value with keywords RSCONST or RSCONSTT in the PROPS section. This results in the model being run as a dead oil problem with no active gas phase. However, OPM Flow takes into account the constant Rs in the calculations and reporting.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	RS	A real positive value that defines the dead oil GOR for all oil PVT tables in the model			
		Mscf/stb	sm^3/sm^3	scc/scc	None
2	PRESS	A real positive value that defines that saturation pressure (bubble point pressure) for all the oil PVT tables in the model.			
		psia	barsa	atma	None
Notes: 1) The keyword is terminated by a "/".					

Table 8.133: RSCONST Keyword Description

See also the RSCONSTT keyword to define a different constant Rs to the various dead oil PVT tables and the PVDO and PVCDO keywords to enter the dead oil properties. All of the aforementioned keywords are in the PROPS section.

Example

The example sets the dead oil GOR to 5 scf/stb and the bubble point pressure to 14.7 psia.

```
--
--       DEAD OIL PVT CONSTANT GOR AND SATURATION PRESSURE
--
RSCONST
--       RS        PSAT
--       MSCF/STB  PSIA
--       --------  ------
          0.0050    14.7                              /
```

[232] *"Dead" oil is oil that it contains no dissolved gas or a relatively thick oil or residue that has lost its volatile components.*

8.3.256 RSCONSTT – DEFINE CONSTANT GOR (RS) FOR EACH DEAD OIL PVT FLUID

Description

RSCONSTT defines a constant Gas-Oil Ratio ("GOR"), for each dead oil[233] PVT fluid in the model. If the oil has a constant and uniform dissolved gas concentration, GOR, and if the reservoir pressure never drops below the saturation pressure (bubble point pressure), then the model can be run more efficiently by omitting the GAS and DISGAS keywords from the RUNSPEC section, treating the oil as a dead oil, and defining a constant Rs (GOR) value with keywords RSCONST or RSCONSTT in the PROPS section. This results in the model being run as a dead oil problem with no active gas phase. However, OPM Flow takes into account the constant Rs in the calculations and reporting.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	RS	A real positive columnar vector that defines the dead oil GOR for each oil PVT table in the model			
		Mscf/stb	sm^3/sm^3	scc/scc	None
2	PRESS	A real positive columnar vector that defines the saturation pressure (bubble point pressure) for each the oil PVT table in the model.			
		psia	barsa	atma	None

Notes:

1) The keyword is followed by NTPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each row must contain two values representing the RS and PRESS variables.
3) Each row is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.134: RSCONSTT Keyword Description

See also the RSCONST keyword to define a constant Rs to all the various dead oil PVT tables and the PVDO and PVCDO keywords to enter the dead oil properties. All of the aforementioned keywords are in the PROPS section.

[233] *"Dead" oil is oil that it contains no dissolved gas or a relatively thick oil or residue that has lost its volatile components.*

Example

The example sets the dead oil GOR to 5, 6.5 and 8.0 scf/stb for PVT tables one, two and three, respectively and the bubble point pressure to 14.7 psia for all three tables.

```
--
--       DEAD OIL PVT CONSTANT GOR AND SATURATION PRESSURE
--
RSCONSTT
--       RS        PSAT
--       MSCF/STB  PSIA
--       --------  ------
          0.0050     14.7                                / TABLE NO. 01
          0.0065     14.7                                / TABLE NO. 02
          0.0080     14.7                                / TABLE NO. 03
```

8.3.257 RSGI – DEFINE GAS-OIL RATIO VERSUS PRESSURE AND GI TABLES

Description

The RSGI keyword specifies the saturated oil Gas-Oil Ratio ("GOR") factors used to specify the variation of the maximum possible GOR of oil with respect to pressure and Gi values, for when the GIMODEL keyword in the RUNSPEC section has been used to activate the GI Pseudo Compositional option for the run. See also the GINODE, RSGI, RVGI, BGGI and BOGI keywords in the PROPS section to describe the fluid properties for the GI Pseudo Compositional option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.258 RTEMP - DEFINE THE INITIAL RESERVOIR TEMPERATURE FOR THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the initial reservoir temperature for the model. Note that the RTEMP keyword is an alias for RTEMPA, and that both keywords are supported by OPM Flow, in both the PROPS and SOLUTION sections, but are treated as being mutually exclusive.

The initial reservoir temperature must be defined when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil temperature model, and the THERMAL keyword to activate the compositional thermal model.

The initial reservoir temperature should be defined when OPM Flow's CO_2 or H_2 storage option has been activated by the CO2STORE or H2STORE keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	RTEMP	Single real positive value that defines the reservoir temperature for the model.			
		°F	°C	°C	None
Notes: 1) The keyword is terminated by a "/".					

Table 8.135: RTEMP Keyword Description

See also the RTEMPVD keyword in SOLUTION section to define the reservoir temperature as a function of depth.

Example

```
--
--        RESERVOIR
--        TEMPERATURE
--        -----------
RTEMP
          190.0                                        / RESERVOIR TEMPERATURE
```

The above example defines the reservoir temperature to be 190 oF.

8.3.259 RTEMPA - DEFINE THE INITIAL RESERVOIR TEMPERATURE FOR THE MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the initial reservoir temperature for the model. Note that the RTEMPA keyword is an alias for RTEMP, and that both keywords are supported by OPM Flow, in both the PROPS and SOLUTION sections, but are treated as being mutually exclusive.

The initial reservoir temperature must be defined when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil temperature model, and the THERMAL keyword to activate the compositional thermal model.

The initial reservoir temperature should be defined when OPM Flow's CO_2 or H_2 storage option has been activated by the CO2STORE or H2STORE keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	RTEMPA	Single real positive value that define the reservoir temperature for the model.			
		°F	°C	°C	None
Notes: 1) The keyword is terminated by a "/".					

Table 8.136: RTEMPA Keyword Description

See also the RTEMPVD keyword in SOLUTION section to define the reservoir temperature as a function of depth.

Example

```
--
--        RESERVOIR
--        TEMPERATURE
--        -----------
RTEMPA
          190.0                                        / RESERVOIR TEMPERATURE
```

The above example defines the reservoir temperature to be 190 oF.

8.3.260 RTEMPVD - DEFINE THE INITIAL RESERVOIR TEMPERATURE VERSUS DEPTH TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the initial reservoir temperature versus depth tables for each equilibration region. Note that the RTEMPVD keyword is an alias for TEMPVD, and that both keywords are supported by OPM Flow, in both the PROPS and SOLUTION sections, but are treated as being mutually exclusive.

See *RTEMPVD - Define the Initial Reservoir Temperature versus Depth Tables* in the SOLUTION section, as the keyword is documented in the SOLUTION section, the same as the commercial simulator, but it can also be used in the PROPS section by OPM Flow.

8.3.261 RVCONST – DEFINE CONSTANT CGR (RV) FOR ALL DRY GAS PVT FLUIDS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

RVCONST defines a constant Condensate-Gas Ratio ("CGR" or Rv), for all dry gas[234] PVT fluids. If the gas has a constant and uniform dissolved condensate concentration, and if the reservoir pressure never drops below the saturation pressure (dew point pressure), then the model can be run more efficiently by omitting the OIL and VAPOIL keywords from the RUNSPEC section, treating the gas as a dry gas, and defining a constant Rv (CGR) value with keywords RVCONST or RVCONSTT in the PROPS section. This results in the model being run as a dry gas problem with no active oil phase. However, OPM Flow takes into account the constant Rv in the calculations and reporting.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	RV	A real positive value that defines the dry gas CGR for all dry gas PVT tables in the model			
		stb/Mscf	sm^3/sm^3	scc/scc	None
2	PRESS	A real positive value that defines that saturation pressure (dew point pressure) for all the dry gas PVT tables in the model.			
		psia	barsa	atma	0.0
Notes: 1) The keyword is terminated by a "/".					

Table 8.137: RVCONST Keyword Description

See also the RVCONSTT keyword to define a different constant Rv to the various dry gas PVT tables and the PVDG keyword to enter the dry gas properties. All of the aforementioned keywords are in the PROPS section.

Example

The example sets the dry gas CGR to 5 stb/MMscf and the bubble point pressure to 14.7 psia.

```
--
--       DRY GAS PVT CONSTANT GCR AND SATURATION PRESSURE
--
RVCONST
--       RV         PSAT
--       STB/MSCF   PSIA
--       --------   ------
          0.0050     14.7                                /
```

[234] *Natural gas that occurs in the absence of condensate or liquid hydrocarbons, or gas that had condensable hydrocarbons removed, is called dry gas. It is primarily methane with some intermediates. The hydrocarbon mixture is solely gas in the reservoir and there is no liquid (condensate surface liquid) formed either in the reservoir or at surface. The term dry indicates that the gas does not contain heavier hydrocarbons to form liquids at the surface conditions. Dry gas typically has GOR's greater than 100,000 scf/stb or 18,000 Sm3/m3.*

8.3.262 RVCONSTT – DEFINE CONSTANT CGR (RV) FOR EACH DRY GAS PVT FLUID

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

RVCONSTT defines a constant Condensate-Gas Ratio ("CGR" or Rv), for each dry gas[235] PVT fluid. If the gas has a constant and uniform dissolved condensate concentration, and if the reservoir pressure never drops below the saturation pressure (dew point pressure), then the model can be run more efficiently by omitting the OIL and VAPGAS keywords from the RUNSPEC section, treating the gas as a dry gas, and defining a constant Rv (CGR) value with keywords RVCONST or RVCONSTT in the PROPS section. This results in the model being run as a dry gas problem with no active oil phase. However, OPM Flow takes into account the constant Rv in the calculations and reporting.

This keyword is ignored by OPM Flow but is documented here for completeness.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	RS	A real positive value that defines the dry gas CGR for each dry gas PVT table in the model			
		stb/Mscf	sm^3/sm^3	scc/scc	None
2	PRESS	A real positive value that defines that saturation pressure (dew point pressure) for each dry gas PVT table in the model.			
		psia	barsa	atma	0.0

Notes:

1) The keyword is followed by NTPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each row must contain two values representing the RV and PRESS variables.
3) Each row is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.138: RVCONSTT Keyword Description

See also the RVCONST keyword to define a constant Rv to all the various dry gas PVT tables and the PVDG keyword to enter the dry gas properties. All of the aforementioned keywords are in the PROPS section.

[235] *Natural gas that occurs in the absence of condensate or liquid hydrocarbons, or gas that had condensable hydrocarbons removed, is called dry gas. It is primarily methane with some intermediates. The hydrocarbon mixture is solely gas in the reservoir and there is no liquid (condensate surface liquid) formed either in the reservoir or at surface. The term dry indicates that the gas does not contain heavier hydrocarbons to form liquids at the surface conditions. Dry gas typically has GOR's greater than 100,000 scf/stb or 18,000 Sm3/m3.*

Example

The example sets the dry gas CGR to 5, 6.5 and 8.0 stb/MMscf for PVT tables one, two and three, respectively and the bubble point pressure to 14.7 psia for all three tables.

```
--
--       DRY GAS PVT CONSTANT GCR AND SATURATION PRESSURE
--
RVCONSTT
--       RV         PSAT
--       STB/MSCF   PSIA
--       --------   ------
          0.0050      14.7                                  / TABLE NO. 01
          0.0065      14.7                                  / TABLE NO. 02
          0.0080      14.7                                  / TABLE NO. 03
```

8.3.263 RVGI – DEFINE CONDENSATE-GAS RATIO VERSUS PRESSURE AND GI TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The RVGI keyword specifies the saturated gas Condensate-Gas Ratio ("CGR") factors used to specify the variation of the maximum possible CGR of gas with respect to pressure and Gi values, for when the GIMODEL keyword in the RUNSPEC section has been used to activate the GI Pseudo Compositional option for the run. See also the GINODE, RSGI, RVGI, BGGI and BOGI keywords in the PROPS section to describe the fluid properties for the GI Pseudo Compositional option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.264 RWGSALT – WATER VAPORIZATION VERSUS PRESSURE AND SALT CONCENTRATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

RWGSALT defines the relationship of water vaporization versus pressure and salt concentration. This keyword should be used when the VAPWAT keyword has be declared in the RUNSPEC section indicating that vaporized water is present in the gas phase. In addition, if the Salt Precipitation model has been activated via the BRINE and PRECSALT keywords, also in the RUNSPEC section, then this keyword must be present. The keyword may be used for gas-water and oil-water-gas input decks that contain the either dry or wet gas and vaporized water phases.

Note

This is an OPM Flow specific keyword for the simulator's Water Vaporization and Salt Precipitation Models, note that these are extensions to the simulator's standard Brine model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A real monotonically increasing down the column values that define the gas phase pressure, that together with salt concentration, defines the vaporized water in gas ratio ("VWGR") or Rw			
		psia	barsa	atma	None
2	SALTCON	A real monotonically increasing positive columnar vector defining the salt concentration in water.			
		lb/stb	kg/sm3	gm/scc	None
3	RW	A columnar vector of real positive number values defining the vaporized water in gas ratio (Rw) that for a given PRESS and SALTCON.			
		stb/Mscf	sm^3/sm^3	scc/scc	None

Notes:

1) Each table is terminated by a "/" including the last table; however, there is no "/" terminator for the keyword.

Table 8.139: RWGSALT Keyword Description

Since the water component is in both the water and the gas phases, RWGSALT controls the amount of water component evaporated from the water phase into the gas phase, which is a function of both the water phase salinity and a grid cells pressure. The keyword should be used in conjunction with the dry gas PVTGW keyword or the wet gas PVTGWO keyword, both of which are in the PROPS section.

Example

The example defines two RWGSALT tables assuming NTPVT equals two and NPPVT is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section.

```
--
--       WATER VAPORIZATION TABLE FOR BRINE  (OPM FLOW KEYWORD)
--
RWGSALT
--       PRES     SALTCONC    RVW
--       PSIA     LB/STB      STB/MSCF
--       ------  ----------   ---------
          300     0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
           600    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
           900    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          1200    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          1500    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /

          2100    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          2400    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
                                                          / Table NO. 1
--       PRES     SALTCONC    RW
--       PSIA     LB/STB      STB/MSCF
--       ------  ----------   ---------
          300     0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          600     0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          900     0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          1200    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          1500    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          1800    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          2100    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
          2400    0           0.000132
                  0.5         0.000132
                  1           0.000132                    /
                                                          / Table NO. 2
```

8.3.265 SALINITY – DEFINE THE RESERVOIR SALINITY FOR ALL CELLS

Description

SALINITY defines a grid blocks salinity for all cells. The keyword should only be used with OPM Flow's CO2-Brine model which is activated via the CO2STORE keyword in the RUNSPEC section. This keyword is a compositional keyword in the commercial simulator but has been implemented in OPM Flow's black-oil CO2-Brine model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SALINITY	A real positive value that defines the salinity for all grid blocks in the model for when the CO2-Brine model has been activated. Note that the units for salinity are molality, that is gm-M/Kg, and therefore the units are defined as given below with the 10^{-3} prefix.			
		10-3 x lb-M/lb	10-3 x kg-M/kg	10-3 x gm-M/gm	None
Notes: 1) The keyword is terminated by a "/".					

Table 8.140: SALINITY Keyword Description

See also the CO2STORE keyword in the RUNSPEC section.

Example

The example sets the salt salinity for all cells in the model to 0.001 lb-M/lb.

```
--
--       SET SALINITY FOR ALL CELLS (OPM FLOW KEYWORD)
--
SALINITY
         1.0                                                  /
```

Note that units for salinity are to the 10-3, that is a value of 0.001 lb-M/lb should be entered as 1.0 lb-M/lb, as per the example.

8.3.266 SALTNODE – SALT CONCENTRATION BASED PVTNUM ARRAY

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SALTNODE defines the salt concentration value based on a cells PVTNUM number. The SALTNODE property is used in the calculation of a polymer viscosity when the polymer and the salt options has been activated by the POLYMER and BRINE keywords in the RUNSPEC section. In the RUNSPEC section the number of PVTNUM functions is declared by NTPVT variable on the TABDIMS keyword and allocated to individual cells by the PVTNUM property array in the REGIONS section. NPPVT on the TABDIMS keyword in the RUNSPEC section defines the maximum number of rows (or pressure values) in the PVT tables and also sets the maximum number of entries for each SALNODE data set. The number of values for each data set must correspond to the number of polymer solution adsorption entries on the PLYADSS keyword. For example if there are three sets of PVT tables and four values on the PLYADSS keyword, then three SALTNODE data sets with four values of salt concentrations need to be entered.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SALTNODE	A real monotonically increasing positive columnar vector defining the salt concentration for a given PVTNUM table.			
		lb/stb	kg/sm3	gm/scc	None
Notes: 1) Each table is terminated by a "/" including the last table; however, there is no "/" terminator for the keyword.					

Table 8.141: SALTNODE Keyword Description

An alternative manner of entering the salt concentrations is by utilizing the PVTNUM region array by using the ADSALNOD keyword in the PROPS section.

Example

Given three sets of relative permeability tables and four values on the PLYADSS keyword and two SALNODE data sets with four values of salt concentrations then the data should be entered as follows:

```
--
--    SETS SALT CONCENTRATION FOR POLYMER SOLUTION ADSORPTION
--    VIA PVTNUM ARRAY ALLOCATION
--
--    SALT
--
SALTNODE
      1.0
      5.0
      10.5
      25.0      / PVTNUM TABLE NO. 01
      1.0
      3.0
      7.5
      15.0      / PVTNUM TABLE NO. 02
```

See also the ADSALNOD keyword.

8.3.267 SALTSOL – DEFINE THE SALT SOLUBILITY LIMIT BY REGION

Description

SALTSOL defines a grid block's maximum salt solubility for each PVTNUM region. The keyword should only be used with OPM Flow's Salt Precipitation model which is activated via the PRECSALT keyword in the RUNSPEC section.

Note

This is an OPM Flow specific keyword for the simulator's Salt Precipitation model that is activated by the PRECSALT keyword and declaring that vaporized water is present in the run via the VAPWAT in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SALTSOL	A real positive value that defines the maximum salt solubility for all grid blocks in a PVTNUM region.			None
		lb/stb	kg/sm3	gm/scc	
2	SALTDEN	SALTDEN is a real number defining the density of salt at surface conditions.			
		lb/ft^3 135.469	kg/m^3 2170	gm/cc 2.170	Defined

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.142: SALTSOL Keyword Description

See also the PRECSALT and VAPWAT keywords in the RUNSPEC section and the PVTGW and PVTGWO keywords in the PROPS section.

Example

The first example sets the maximum salt solubility for all cells in the model to 134.6 lb/stb, assuming that there is only one PVT region, that is NTPVT is equal to one on the TABDIMS keyword in the RUNSPEC section.

```
--
--       SET SALT SOLUBILITY LIMIT FOR EACH REGION (OPM FLOW KEYWORD)
--
SALTSOL
--       MAX       SALT
--       SALTSOL   DENSITY
         134.6     1*                                              /
```

The 134.6 lb/stb, (380 kg/sm3 or 0.384 gm/scc for metric and laboratory units, respectively) is based on the solubility of NACL at 212 °F (100 °C) and should be used with care.

The next example shows how to set the maximum salt solubility for when NTPVT is equal to three on the TABDIMS keyword in the RUNSPEC section.

```
--
--       SET SALT SOLUBILITY LIMIT FOR EACH REGION (OPM FLOW KEYWORD)
--
SALTSOL
         134.6                                          / PVT REGION NO. 1
         124.0                                          / PVT REGION NO. 2
                                                        / PVT REGION NO. 3
```

Here the last entry, which is for region number three, is defaulted, and results in region's three maximum salt solubility to take the previous value, in this case 124.0 lb/stb.

8.3.268 SCALECRS – DEFINE END-POINT SCALING OPTION

Description

The SCALECRS keyword sets the end-point scaling option to be either two-point or three-point scaling, for when the End-Point Scaling option has been invoked by the ENDSCALE keyword in the RUNSPEC section. This determines which end-points on the relative permeability curves are used for scaling based on the supplied end-point arrays (SGCR, SWCR, etc.).

No.	Name	Description	Default
1	SCALEOPT	SCALEOPT is a character string that sets the end-point scaling option and should be set to either NO or YES: 1) NO: Activates two-point end-point scaling. 2) YES: Activates three-point end-point	NO
Notes: 1) The keyword is terminated by a "/".			

Table 8.143: SCALECRS Keyword Description

The end-point scaled for each option and the arrays used in the end-point scaling are summarized in the following table:

Option	Phases	Relative Permeability End-Point	Minimum Saturation End-Point	Middle Saturation End-Point	Maximum Saturation End-Point
Two-Point	Water	KRW	SWCR		SWU
	Gas	KRG	SGCR		SGU
	Oil-Water	KRORW	SOWCR		(1.0 – SWL - SGL)
	Oil-Gas	KRORG	SOGCR		(1.0 – SWL - SGL)
Three-Point	Water	KRW	SWCR	(1.0 – SOWCR - SGL)	SWU
	Gas	KRG	SGCR	(1.0 - SOGCR-SWL)	SGU
	Oil-Water	KRORW	SOWCR	(1.0 – SWCR - SGL)	(1.0 – SWL - SGL)
	Oil-Gas	KRORG	SOGCR	(1.0 – SGCR - SGL)	(1.0 – SWL - SGL)
	Two Phase Gas-Water Simulations				
	Water	KRW	SWCR	(1.0 - SGCR)	SWU
	Gas	KRG	SGCR	(1.0 -SWCR)	SGU

Table 8.144: End-Point Arrays Used in the End-Point Scaling Options

See also the TZONE keyword in the PROPS section that sets the transition zone end-point scaling options for the oil, gas and water phases.

Example

```
--
--       TWO-POINT END-POINT SCALING IS NO THREE POINT IS YES
--
--       SCALEOPT
--       ---------
SCALECRS
         YES                                                  / SCALING OPTION
```

The above example activates three-point end-point scaling of the relative permeability curves.

8.3.269 SCALELIM – END-POINT SCALING VERSUS DEPTH MAXIMUM WATER SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the maximum water saturation allowed in a cell for when the end-point versus depth tables are used in the End-Point Scaling option to calculate the water saturation for a grid block. The End-Point Scaling option must be invoked by the ENDSCALE keyword in the RUNSPEC section to use this keyword, and the keyword may only be used in two phase runs containing water, or if the Miscible Flood option has been activated by the MISCIBLE keyword in the RUNSPEC section. This keyword functionality is not supported in OPM Flow.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.270 SDENSITY – DEFINE THE MISCIBLE OR SOLVENT SURFACE GAS DENSITY

Description

The SDENSITY keyword defines density at surface conditions of either the miscible injection gas for when the MISCIBLE option has been invoked in the RUNSPEC section, or the solvent for when the SOLVENT option has been invoked in the RUNSPEC section. This keyword must be invoked if either the MISCIBLE or SOLVENT options have been activated in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SDENSITY	SDENSITY is a real positive number defining the density at surface conditions of either: 1) the miscible injection gas for when the MISCIBLE option has been invoked in the RUNSPEC section, or, 2) the solvent for when the SOLVENT option has been invoked in the RUNSPEC section.			
		lb/ft^3	kg/m^3	gm/cc	None
Notes: 1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section. 2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.					

Table 8.145: SDENSITY Keyword Description

In addition to this keyword, the surface density or gravity of the in-place natural gas must be entered using either the DENSITY or GRAVITY keywords.

Examples

The following shows the SDENSITY keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to one.

```
--
--       MIS-SOL
--       DENSITY
--       -------
SDENSITY
         0.04520                                        / MIS-SOL DENSITY
```

The next example shows the SDENSITY keyword for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to three.

```
--
--       MIS-SOL
--       DENSITY
--       -------
SDENSITY
         0.04520                                        / MIS-SOL DENSITY 1
         0.05520                                        / MIS-SOL DENSITY 2
         0.06420                                        / MIS-SOL DENSITY 3
```

There is no terminating "/" for this keyword.

8.3.271 SGCR – END-POINT SCALING GRID CELL CRITICAL GAS SATURATIONS

Description

SGCR defines the critical gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The critical gas saturation is defined as the maximum gas saturation for which the gas relative permeability is zero in a two-phase relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGCR	SGCR is an array of real numbers assigning the critical gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.03			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the critical gas saturation used with the end-point scaling option. If directional end-point scaling has been activated then the SGCRX± , SGCRX± and SGCRX± series of keyword should be used.
2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
3) The keyword is terminated by a "/".

Table 8.146: SGCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KRGR, KRO, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SGCRX, SGCRY and SGCRZ instead of SGCR. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SGCRX, SGCRX-, SGCRY, SGCRY-, SGCRZ and SGCRZ-, instead of the SGCR keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SGCR DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SGCR
         300*0.050                                                    /
```

The above example defines a constant critical gas saturation of 0.05 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.272 SGCWMIS – MISCIBLE CRITICAL GAS VERSUS WATER SATURATION FUNCTIONS

Description

SGCWMIS defines the dependency between the miscible critical gas saturation and the water saturation, for when the MISCIBLE keyword in the RUNSPEC section has been activated. The keyword can only be used with the MISCIBLE option and for when the oil, water and gas phases are active in the model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWAT	A columnar vector of real monotonically increasing down the column values starting from zero and terminating atone, that defines the water saturation.			
		dimensionless	dimensionless	dimensionless	None
2	SGCMIS	A columnar vector of real equal or increasing down the column values that are greater than or equal to zero and less than one, that define the corresponding miscible gas critical gas saturation for the corresponding water saturation SWAT.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTMISC tables as declared on the MISCIBLE keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSMISC rows as declared on the MISCIBLE keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.147: SGCWMIS Keyword Description

Example

```
--
--       MISCIBLE CRITICAL GAS VERSUS WATER SATURATION TABLE
--
SGCWMIS
--       SWAT       SGCRMIS
--       FRAC       FRAC
--       -------    --------
          0.0000     0.0000
          0.2000     0.0300
          1.0000     0.0300                              / TABLE NO. 01
--       SWAT       SGCRMIS
--       FRAC       FRAC
--       -------    --------
          0.0000     0.0000
          0.3000     0.0500
          1.0000     0.0500                              / TABLE NO. 02
```

The above example defines two miscible critical gas saturation versus water saturation tables assuming NTMISC equals two and NSMISC is greater than or equal to three on the MISCIBLE keyword in the RUNSPEC section.

8.3.273 SGF32D – GAS SATURATION TABLES VERSUS OIL AND WATER SATURATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SGF32D keyword defines the gas relative permeability as a function of both oil and water saturations. This keyword should only be used if the gas is present in the run.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

See also the SWOF, SGOF, SLGOF series of keywords and the SWFN, SGFN, SGWFN, SOF2, SOF3, SOF32D series of keywords to enter relative permeability data.

8.3.274 SGFN – GAS SATURATION TABLES (FORMAT TYPE 2)

Description

The SGFN keyword defines the gas relative permeability and oil-gas capillary pressure data versus gas saturation tables for when gas is present in the input deck. This keyword should only be used if the gas is present in the run.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGAS	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the gas saturation.			
		dimensionless	dimensionless	dimensionless	None
2	KRG	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the gas relative permeability.			
		dimensionless	dimensionless	dimensionless	None
3	PCOG	A columnar vector of real values that are either equal or increasing down the column that defines the oil-gas capillary pressure.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.148: SGFN Keyword Description

See also the *GSF - Gas Saturation Function Tables (Gas-Water Systems)* keyword in the PROPS section, that defines the gas relative permeability and gas-water capillary pressure data as a function of gas saturation, for when only the gas and water phases are present in the model. Note that the GSF keyword must be used in conjunction with the *WSF - Water Saturation Tables versus Water Saturation (Gas-Water and CO2STORE Systems)* keyword, also in the PROPS section. WSF defines the water saturation as a function of water saturation for when only the gas and water phases are present in the model.

Example

```
--
--       GAS RELATIVE PERMEABILITY TABLES (SGFN)
--
SGFN
--       SGAS       KRG        PCGO
--       FRAC                  PSIA
--       --------  --------   -------
             0.00    0.0000      0.0
             0.05    0.0000      0.0
             0.10    0.0000      0.0
             0.15    0.0000      0.0
             0.20    0.0002      0.0
             0.25    0.0010      0.0
             0.30    0.0062      0.0
             0.35    0.0140      0.0
             0.40    0.0273      0.0
             0.45    0.0450      0.0
             0.50    0.0707      0.0
             0.55    0.1020      0.0
             0.60    0.1412      0.0
             0.65    0.1870      0.0
             0.70    0.2412      0.0
             0.77    0.3288      0.0
             0.82    0.4000      0.0
             0.85    0.4450      0.0                    / TABLE NO. 01
--       SGAS       KRG        PCGO
--       FRAC                  PSIA
--       --------  --------   -------
             0.00    0.0000      0.0
             0.05    0.0000      0.0
             0.10    0.0000      0.0
             0.15    0.0000      0.0
             0.20    0.0002      0.0
             0.25    0.0010      0.0
             0.30    0.0062      0.0
             0.35    0.0140      0.0
             0.40    0.0273      0.0
             0.45    0.0450      0.0
             0.50    0.0707      0.0
             0.55    0.1020      0.0
             0.60    0.1412      0.0
             0.65    0.1870      0.0
             0.70    0.2412      0.0
             0.77    0.3288      0.0
             0.82    0.4000      0.0
             0.85    0.4450      0.0                    / TABLE NO. 02
```

The example defines two SGFN tables for when gas is present in the input deck.

8.3.275 SGL – END-POINT SCALING GRID CELL CONNATE GAS SATURATIONS

Description

SGL defines the connate gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The connate gas saturation is defined as the minimum gas saturation in a two-phase gas relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGL	SGL is an array of real numbers assigning the connate gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.03			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the connate gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the SGLX± , SGLY± and SGZ± series of keyword should be used.
2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
3) The keyword is terminated by a "/".

Table 8.149: SGL Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SGLX, SGLY and SGLZ instead of SGL. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SGLX, SGLX-, SGLY, SGLY-, SGLZ and SGLZ-, instead of the SGL keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SGL DATA FOR ALL CELLS
--      (FOR NX x NY x NZ = 300)
--
SGL
         300*0.030                                                    /
```

The above example defines a constant connate gas saturation of 0.03 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.276 SGLPC – END-POINT SCALING GRID CELL CAPILLARY PRESSURE CONNATE GAS SATURATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SGLPC defines the connate gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The connate gas saturation is defined as the minimum gas saturation in a two-phase gas relative permeability table. The keyword only applies the scaling to the drainage capillary pressure tables, unlike the SGL keyword that applies the scaling to both the capillary pressure and relative permeability tables. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGLPC	SGLPC is an array of real numbers assigning the connate gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. If SGLPC is omitted from the input deck the values will be defaulted to those on the SGL series of keywords. If the SGL series of keywords are missing from the input deck then the values are taken from the cell allocated capillary pressure table. Repeat counts may be used, for example 30*0.03			Taken from SGL or from the cell allocated capillary pressure table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the connate gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the SGLX± , SGLY± and SGZ± series of keyword should be used.

2) The keyword is terminated by a "/".

Table 8.150: SGLPC Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KRGR, KRO, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SGLX, SGLY and SGLZ instead of SGL or SGLPC. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SGLX, SGLX-, SGLY, SGLY-, SGLZ and SGLZ-, instead of the SGL or SGLPC keywords.

Missing Some Functionality - Use with Caution.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SGLPC DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SGLPC
         300*0.030                                                              /
```

The above example defines a constant connate gas saturation of 0.03 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.277 SGOF – GAS-OIL SATURATION TABLES VERSUS GAS (FORMAT TYPE 1)

Description

The SGOF keyword defines the oil and gas relative permeability and oil-gas capillary versus gas saturation tables for when oil and gas are present in the input deck. This keyword should only be used if both oil and gas are present in the run.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGAS	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the gas saturation.			
		dimensionless	dimensionless	dimensionless	None
2	KRG	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the gas relative permeability.			
		dimensionless	dimensionless	dimensionless	None
3	KRO	A columnar vector of real values that are either equal or decreasing down the column and that are greater than or equal to zero and less than or equal to one that defines the oil relative permeability with respect to gas and connate water saturation. When water is active in the run, the first entry the column, that is at krog(Sg = 0), must be the same as the first entry in the corresponding SWOF table, that is at krow(So = 1 - Swco). The last value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None
4	PCOG	A columnar vector of real values that are either equal or increasing down the column that defines the oil-gas relative capillary pressure.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.151: SGOF Keyword Description

Example

The following example is based on NTSFUN equals two on the TABDIMS keyword in the RUNSPEC section.

```
--
--       GAS-OIL RELATIVE PERMEABILITY TABLES (SGOF)
SGOF
--       SG          KRG        KROG       PCOG
--       FRAC                              PSIA
--       -------   --------   -------    -------
         0.00000   0.000000   0.90000    0.0000
         0.03000   0.000000   0.82500    0.0000
         0.80000   0.900000   0.00000    0.0000             / TABLE No. 01
--       -------   --------   -------    -------
         0.00000   0.000000   0.90000    0.0000
         0.03000   0.000000   0.82500    0.0000
         0.04420   0.024200   0.80000    0.0000

```

The example defines two SGOF tables for use when oil, gas and water are present in the run.

8.3.278 SGOFLET– GAS-OIL LET RELATIVE PERMEABILITY FUNCTIONS

Description

SGOFLET defines the relative permeability and capillary pressure parameters for the gas-oil LET family of models. Both the gas and oil phases should be made active in the model via the GAS and OIL keywords in the RUNSPEC section. See section *8.2.6Saturation Table Generation - LET Functions* and Lomeland et al.[236],[237] [238] and [239] for further information on the model.

The keyword is used as a replacement for the SGOF keyword for three-phase oil-gas-water systems, and the LET series of keywords cannot be combined with the standard set of relative permeability keywords.

Note

This is an OPM Flow specific keyword and will therefore cause an error in the commercial simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGL	SGL is a real positive number less than one that defines the connate gas saturation, that is smallest gas saturation in the LET function.			0.0
		dimensionless	dimensionless	dimensionless	
2	SGCR	SGCR is a real positive number greater than or equal to SGL and less than one, that defines the critical gas saturation, that is the largest gas saturation for which the gas relative permeability is zero.			0.0
		dimensionless	dimensionless	dimensionless	
3	LGAS	LGAS is a real positive number that defines the LET Lower empirical parameter Lg for the gas phase with the associated oil phase in the LET relative permeability equation.			1.0
		dimensionless	dimensionless	dimensionless	
4	EGAS	EGAS is a real positive number that defines the LET Elevation empirical parameter Eg for the gas phase with the associated oil phase in the LET relative permeability equation.			1.0
		dimensionless	dimensionless	dimensionless

17	PCIT	PCIT is a real positive number that defines the gas-oil threshold capillary pressure at the maximum water saturation in the LET capillary pressure equations.			
		psia	bars	atm	0.0

Notes:

1) The keyword is followed by NTSFUN definitions as declared on the TABDIMS keyword in the RUNSPEC section, with each definition consisting of the above 17 LET parameters.
2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.152: SGOFLET Keyword Description

Note there a two versions of the LET functions, LET[236] for two-phase flowing conditions and LETx[240] for three-phase flowing conditions. This keyword implements the LET version for a gas-oil system.

The functions are dependent on the drainage and imbibition cycle of the wetting phase as well as drainage and inhibition cycle number, since a reservoir may undergo several flooding events. To account for this the system defines the flooding event using the three saturations: Sw, So, and Sg together with the state of the three saturations during the flooding event. The saturation state can be Increasing, Decreasing, or Constant, for a given flooding event cycle number (n). Thus, Sw(D), So(I), Sg(C)1or DIC1, means the water phase is decreasing, the oil phase is increasing and the gas phase is constant for the primary or first cycle (n equals one). This is case for when oil is migrating into the reservoir rock and displacing the initial water contained with the reservoir.

Note

All the LET parameters are dependent on the flooding event and flooding cycle, and thus are expected vary as such. To be clear, the values of SGCR, Lg, Lo etc. should be different for each flooding cycle.

See also the *SGWFLET – Gas-Water LET Relative Permeability Functions*, and *SWOFLET – Water-Oil LET Relative Permeability Functions* keywords in this section.

[240] *Lomeland F. and Ebeltoft E., 2013. Versatile Three-phase Correlations for Relative Permeability and Capillary Pressure. Paper SCA2013-034 presented at the International Symposium of the Society of Core Analysts held in Napa Valley, California, USA, 16-19 September, 2013.*

Example

The following example uses the SGOFLET keyword to define two relative gas-oil relative permeability tables, based on NTSFUN equals two on the TABDIMS keyword in the RUNSPEC section.

```
--
--       SGOFLET – GAS-OIL LET REL. PERMEABILITY FUNCTIONS (OPM FLOW KEYWORD)
--
SGOFLET
--       SGL       SGCR     L-GAS     E-GAS     T-GAS     KRT-GAS
--       SOR       SOGCR    L-OIL     E-OIL     T-OIL     KRT-OIL
--       L-PC      E-PC     T-PC      PCIR      PCIT
--       -------   ------   -------   -------   -------   -------
         0.00000   0.0000   1.00000   1.00000   1.00000   1.00000
         0.00000   0.0000   1.00000   1.00000   1.00000   1.00000
         1*        1*       1*        1*        1*                / TABLE NO. 01

         0.00000   0.0000   1.00000   1.00000   1.00000   1.00000
         0.00000   0.0000   1.00000   1.00000   1.00000   1.00000
         1*        1*       1*        1*        1*                / TABLE NO. 02
```

Here the SGOFLET keyword parameters are all set to their default values.

8.3.279 SGU – END-POINT SCALING GRID CELL GAS SATURATION

Description

SGU defines the maximum gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The maximum gas saturation is defined as the maximum gas saturation in a two-phase gas relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGU	SGU is an array of real numbers assigning the maximum gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.70			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the maximum gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the SGUX± , SGUX± and SGU± series of keyword should be used.
2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
3) The keyword is terminated by a "/".

Table 8.153: SGU Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SGUX, SGUY and SGUZ instead of SGU. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SGUX, SGUX-, SGUY, SGUY-, SGUZ and SGUZ-, instead of the SGU keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SGU DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SGU
         300*0.700                                                    /
```

The above example defines a constant connate gas saturation of 0.70 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.280 SGWFLET – GAS-WATER LET RELATIVE PERMEABILITY FUNCTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SWGFLET defines the relative permeability and capillary pressure parameters for the water-gas LET family of models. Both the gas and water phases should be made active in the model via the GAS and WATER keywords in the RUNSPEC section. This keyword should only be used in two-phase models containing the gas and water phases only, that is the oil phase must be absent. See section *8.2.6Saturation Table Generation - LET Functions* and Lomeland et al.[241],[242] [243] and [244] for further information on the model.

The keyword is used as a replacement for the SGWFN keyword for two-phase gas-water systems, and the LET series of keywords cannot be combined with the standard set of relative permeability keywords.

Note

This is an OPM Flow specific keyword and will therefore cause an error in the commercial simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGL	SGL is a real positive number less than one that defines the connate gas saturation, that is smallest gas saturation in the LET function.			0.0

		psia	bars	atm	

Notes:

1) The keyword is followed by NTSFUN definitions as declared on the TABDIMS keyword in the RUNSPEC section, with each definition consisting of the above 17 LET parameters.
1) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.154: SGWFLET Keyword Description

Note there a two versions of the LET functions, LET[241] for two-phase flowing conditions and LETx[245] for three-phase flowing conditions. This keyword implements the LET version for a gas-water system.

The functions are dependent on the drainage and imbibition cycle of the wetting phase as well as drainage and inhibition cycle number, since a reservoir may undergo several flooding events. To account for this the system defines the flooding event using the three saturations: Sw, So, and Sg together with the state of the three saturations during the flooding event. The saturation state can be Increasing, Decreasing, or Constant, for a given flooding event cycle number (n). Thus, Sw(D), So(C), Sg(I), or DCI1, means the water phase is decreasing, the oil phase is constant and the gas phase is increasing for the primary or first cycle (n equals one). This is case for when gas is migrating into the reservoir rock and displacing the initial water contained with the reservoir.

Note

All the LET parameters are dependent on the flooding event and flooding cycle, and thus are expected vary as such. To be clear, the values of SWCR, Lg, Lw etc. should be different for each flooding cycle.

See also the *SGOFLET– Gas-Oil LET Relative Permeability Functions*, and *SWOFLET – Water-Oil LET Relative Permeability Functions* keywords in this section, that may be used for three-phase systems.

[245] *Lomeland F. and Ebeltoft E., 2013. Versatile Three-phase Correlations for Relative Permeability and Capillary Pressure. Paper SCA2013-034 presented at the International Symposium of the Society of Core Analysts held in Napa Valley, California, USA, 16-19 September, 2013.*

Example

The following example uses the SWGFLET keyword to define two relative gas-water relative permeability tables, based on NTSFUN equals two on the TABDIMS keyword in the RUNSPEC section.

```
--
--       SGWFLET – GAS-WATER LET REL. PERMEABILITY FUNCTIONS (OPM FLOW KEYWORD)
--
SGWFLET

```

Here the SGWFLET keyword parameters are all set to their default values.

8.3.281 SGWFN – GAS-WATER SATURATION TABLES (FORMAT TYPE 2)

Description

The SGWFN keyword defines the gas and water relative permeability and gas-water capillary pressure data versus gas saturation tables for when gas and water are present in the input deck. This keyword should only be used if gas and water are present in the run.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGAS	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the gas saturation.			
		dimensionless	dimensionless	dimensionless	None
2	KRG	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the gas relative permeability. Note that the first entry in the column must be zero.			
		dimensionless	dimensionless	dimensionless	None
3	KRW	A columnar vector of real values that are either equal or decreasing down the column and that are greater than or equal to zero and less than or equal to one that defines the water relative permeability with respect to gas saturation. The last value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None
4	PCGW	A columnar vector of real values that are either equal or increasing down the column that defines the gas-water relative capillary pressure.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.155: SGWFN Keyword Description

```

The example defines two SGWFN tables for use when oil, gas and water are present in the run.

8.3.282 SHRATE - ACTIVATE AND DEFINE THE POLYMER SHEARING LOGARITHMIC PARAMETERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates the logarithm-based polymer shear thinning/thickening option and defines the shear rate constant. This keyword can only be used in conjunction with the PLYSHLOG in the PROPS section

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

See the PLYSHEAR keyword for the alternative polymer shear thinning/thickening option that is implemented in OPM Flow.

8.3.283 SKIP – ACTIVATE SKIPPING OF ALL KEYWORDS AND INPUT DATA

The SKIP keyword turns on skipping of keywords until the ENDSKIP activation keyword is encountered. All keywords and between the SKIP and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP – Activate Skipping of All Keywords and Input Data* in the GLOBAL section for a full description.

8.3.284 SKIP100 – ACTIVATE SKIPPING OF BLACK-OIL KEYWORDS AND INPUT DATA

This keyword turns on skipping of black-oil keywords until the ENDSKIP activation keyword is encountered. All black-oil keywords between the SKIP100 and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP100 – Activate Skipping of Black-Oil Keywords and Input Data* in the GLOBAL section for a full description.

8.3.285 SKIP300 – ACTIVATE SKIPPING OF "COMPOSITIONAL" KEYWORDS AND INPUT DATA

Turns on skipping of "compositional" keywords until the ENDSKIP activation keyword is encountered. All "compositional" keywords between the SKIP300 and ENDSKIP keywords are ignored by OPM Flow.

See *Error: Reference source not found* in the GLOBAL section for a full description.

8.3.286 SKPRPOLY – POLYMER MOLECULAR WEIGHT MODEL POLYMER INJECTION SKIN TABLE

Description

This keyword, SKPRPOLY, describes the relationship of a water injection well's injected polymer skin pressure as a function of polymer throughput and water velocity, for the simulator's Polymer Molecular Weight Transport option. The table is a two dimensional table that relates the polymer throughput values and water velocity values to derive the resulting wellbore skin pressure of the injected polymer, which is then used to calculate the total wellbore skin pressure based on the polymer concentration.

This keyword should only be used if the POLYMER and POLYMW keywords in the RUNSPEC section are also activated.

Note

This is an OPM Flow specific keyword that employs an alternative polymer flood model based on a Polymer Molecular Weight Transport equation, that is not available in the commercial simulator.

The model has been tested using metric units; however, using either field or laboratory units with the option should be considered experimental.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1-1	SKPRPNUM	A positive integer value greater than zero and less than or equal to the NTSKPOLY variable, as defined on the PINTDIMS keyword in the RUNSPEC section, that defines the SKPRPOLY Polymer Molecular Weight Model polymer injection skin pressure table number.			None
1-2	POLCON	A real positive value that the defines the reference polymer concentration for the table.			None
		lb/stb	kg/sm^3	gm/scc	
2-1	THRUPUT	A real positive monotonically increasing vector, that defines the polymer throughput values. The first entry should be zero to define a no throughput data set, and each vector record should be on a separate line terminated by a "/".			None
		$feet^3/feet^2$	m^3/m^2	cm^3/cm^2	
3-1	VELOCITY	A real positive monotonically increasing vector, that defines the polymer velocity values. The first entry should be zero to define a no velocity data set, and each vector record should be on a separate line terminated by a "/".			None
		feet/day	m/day	cm/hour	

No.	Name	Description			Default
		Field	Metric	Laboratory	
4-1	PRESS	A series of real positive vectors representing the wellbore skin pressure, for the given reference polymer concentration (POLCON), for all combinations of the polymer throughput values (THRUPUT) and velocity values (VELOCITY), organized as a series of vectors PRESS(THRUPUT, VELOCITY). Thus, the first vector represents the wellbore skin pressure of the first THRUPUT value and each entry in the vector is the corresponding wellbore skin pressure of the associated VELOCITY vector. Each vector should be on a separate line and should be terminated by a "/". Thus, if THRUPUT has three entries and VELOCITY has four, then there should be three vectors, with each vector containing four elements representing wellbore skin pressure values, as a function of THRUPUT and VELOCITY.			None
		psia	barsa	atma	

Notes:

1) The keyword should be terminated by a "/", but may be repeated up to NTSKPOLY times, as per the PINTDIMS keyword in the RUNSPEC section, to allow for the input of multiple tables.

Table 8.156: SKPRPOLY Keyword Description

Unlike other PROPS section table keywords, that enable multiple tables following the keyword to be entered, the SKPRPOLY keyword requires that the keyword itself must be repeated for each table, as is shown in the example on the following page.

The WSKPTAB keyword in the SCHEDULE section may be used to assign the SKPRPOLY and SKPRWAT tables to water injections wells, that enable the calculation of the wellbore skin pressure based on the fluids being injected.

See also the SKPRWAT, PLYMWINJ, and PLYVMH keywords, in the PROPS section, that are the additional property keywords required for the Polymer Molecular Weight Transport option. In addition, see also the WPMITAB keyword in the SCHEDULE section, that assigns the PLYMWINJ tables to the water injection wells.

Note that the standard polymer property data keywords: PLYROCK, PLYADS, PLYMAX, etc., are still required to fully describe the polymer fluid.

Example

Given NTSKPOLY equals two on the PINTDIMS keyword in the RUNSPEC section, then two SKPRPOLY tables are required to be entered:

```
--
--       POLYMER MOLECULAR WEIGHT MODEL POLYMER INJECTION SKIN TABLE
--       (OPM FLOW PROPS KEYWORD)
--
SKPRPOLY
--       TABLE   POLYMER REF
--       NO.     CONCENTRATION
         1       2.00                  /
--
--       THROUGHPUT VALUES
--
         0.0     200.0   400.0         /
--
--       VELOCITY VALUES
--
         0.0     50.0    80.0    100.0 /
--
--       PRESS SKIN VALUES
--
         0.0     10.0    20.0    40.0  / PRESS(THRUPUT=1, VELOCITY=1 TO N)
         0.0     50.0    100.0   200.0 / PRESS(THRUPUT=2, VELOCITY=1 TO N)
         0.0     100.0   200.0   400.0 / PRESS(THRUPUT=3, VELOCITY=1 TO N)
/
SKPRPOLY
--       TABLE   POLYMER REF
--       NO.     CONCENTRATION
         2       2.0                   /
--
--       THROUGHPUT VALUES
--
         0.0     200.0   400.0         /
--
--       VELOCITY VALUES
--
         0.0     30.0    50.0    100.0 /
--
--       PRESS SKIN VALUES
--
         0.0     10.0    20.0    40.0  / PRESS(THRUPUT=1, VELOCITY=1 TO N)
         0.0     50.0    100.0   200.0 / PRESS(THRUPUT=2, VELOCITY=1 TO N)
         0.0     100.0   200.0   400.0 / PRESS(THRUPUT=3, VELOCITY=1 TO N)
/
```

As mentioned previously, the SKPRPOLY keyword requires that the keyword itself must be repeated for each table, as is shown in the above example.

8.3.287 SKPRWAT – POLYMER MOLECULAR WEIGHT MODEL WATER INJECTION SKIN TABLE

Description

This keyword, SKPRWAT, describes the relationship of a water injection well's injected water skin pressure as a function of water throughput and water velocity, for the simulator's Polymer Molecular Weight Transport option. The table is a two dimensional table that relates the water throughput values and water velocity values to derive the resulting wellbore skin pressure of the injected water, which is then used to calculate the total wellbore skin pressure based on the polymer concentration.

This keyword should only be used if the POLYMER and POLYMW keywords in the RUNSPEC section are also activated.

Note

This is an OPM Flow specific keyword that employs an alternative polymer flood model based on a Polymer Molecular Weight Transport equation, that is not available in the commercial simulator.

The model has been tested using metric units; however, using either field or laboratory units with the option should be considered experimental.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1-1	SKPRWNUM	A positive integer value greater than zero and less than or equal to the NTSKWAT variable, as defined on the PINTDIMS keyword in the RUNSPEC section, that defines the SKPRWAT Polymer Molecular Weight Model water injection skin pressure table number.			None
2-1	THRUPUT	A real positive monotonically increasing vector, that defines the water throughput values. The first entry should be zero to define a no throughput data set, and each vector record should be on a separate line terminated by a "/".			None
		$feet^3/feet^2$	m^3/m^2	cm^3/cm^2	
3-1	VELOCITY	A real positive monotonically increasing vector, that defines the water velocity values. The first entry should be zero to define a no velocity data set, and each vector record should be on a separate line terminated by a "/".			None
		feet/day	m/day	cm/hour	

No.	Name	Description			Default
		Field	Metric	Laboratory	
4-1	PRESS	A series of real positive vectors representing the wellbore skin pressure, for all combinations of the water throughput values (THRUPUT) and velocity values (VELOCITY), organized as a series of vectors PRESS(THRUPUT,VELOCITY). Thus, the first vector represents the wellbore skin pressure of the first THRUPUT value and each entry in the vector is the corresponding wellbore skin pressure of the associated VELOCITY vector. Each vector should be on a separate line and should be terminated by a "/". Thus, if THRUPUT has three entries and VELOCITY has four, then there should be three vectors, with each vector containing four elements representing wellbore skin pressure values, as a function of THRUPUT and VELOCITY.			None
		psia	barsa	atma	
Notes: 1) The keyword should be terminated by a "/", but may be repeated up to NTSKWAT times, as per the PINTDIMS keyword in the RUNSPEC section, to allow for the input of multiple tables.					

Table 8.157: SKPRWAT Keyword Description

Unlike other PROPS section table keywords, that enable multiple tables following the keyword to be entered, the SKPRWAT keyword requires that the keyword itself must be repeated for each table, as is shown in the example on the following page.

The WSKPTAB keyword in the SCHEDULE section may be used to assign the SKPRPOLY and SKPRWAT tables to water injections wells, that enable the calculation of the wellbore skin pressure based on the fluids being injected.

See also the SKPRPOLY, PLYMWINJ, and PLYVMH keywords, in the PROPS section, that are the additional property keywords required for the Polymer Molecular Weight Transport option. In addition, see also the WPMITAB keyword in the SCHEDULE section, that assigns the PLYMWINJ tables to the water injection wells.

Note that the standard polymer property data keywords: PLYROCK, PLYADS, PLYMAX, etc., are still required to fully describe the polymer fluid.

Example

Given NTSKWAT equals two on the PINTDIMS keyword in the RUNSPEC section, then two SKPRWAT tables are required to be entered:

```
--
--        POLYMER MOLECULAR WEIGHT MODEL WATER INJECTION SKIN TABLE
--        (OPM FLOW PROPS KEYWORD)
--
SKPRWAT
          1                              / TABLE NUMBER
--
--        THROUGHPUT VALUES
--
          0.0     200.0   400.0          /
--
--        VELOCITY VALUES
--
          0.0     50.0    70.0    100.0 /
--
--        PRESS SKIN VALUES
--
          0.0     2.0     4.0     8.0   / PRESS(THRUPUT=1, VELOCITY=1 TO N)
          0.0     20.0    40.0    80.0  / PRESS(THRUPUT=2, VELOCITY=1 TO N)
          0.0     50.0    100.0   200.0 / PRESS(THRUPUT=3, VELOCITY=1 TO N)
/
SKPRWAT
          2                              / TABLE NUMBER
--
--        THROUGHPUT VALUES
--
          0.0     200.0   400.0          /
--
--        VELOCITY VALUES
--
          0.0     30.0    50.0    100.0 /
--
--        PRESS SKIN VALUES
--
          0.0     2.0     4.0     8.0   / PRESS(THRUPUT=1, VELOCITY=1 TO N)
          0.0     20.0    40.0    80.0  / PRESS(THRUPUT=2, VELOCITY=1 TO N)
          0.0     50.0    100.0   200.0 / PRESS(THRUPUT=3, VELOCITY=1 TO N)
/
```

As mentioned previously, the SKPRWAT keyword requires that the keyword itself must be repeated for each table, as is shown in the above example.

8.3.288 SKRO – END-POINT SCALING OF GRID CELL KRO(SWL) (SURFACTANT)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SKRO defines the scaling parameter for the surfactant oil relative permeability value at the connate water saturation (SWL), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Surfactant option must be enabled by either the SURFST or SURFSTES keywords in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SKRO	SKRO is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling SKRO values for each cell in the model. Repeat counts may be used, for example 50*0.500.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".

Table 8.158: SKRO Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be scale on the relative permeability values using the SKRO, SKRORG, SKRORW, SKRW and SKRWR surfactant relative permeability grid cell arrays for the relative permeability end-point data.

Example

The example defines an input box for the whole grid and for layers one to three, for layer one SKRO is set equal to 0.850, for layer two SKRO equals 0.875, and for layer three SKRO equals 0.900.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)
--
--       ---------- BOX ---------
--       I1  I2   J1  J2   K1  K2
BOX
         1*  1*   1*  1*   1   3                          / DEFINE BOX AREA
--
--       SET SKRO VALUES FOR THREE LAYERS IN THE MODEL
--
SKRO
         1000*0.855  1000*0.875  1000.0.900               /
--
--       DEFINE END OF INPUT BOX EDITING OF INPUT ARRAYS
--
ENDBOX
```

8.3.289 SKRORG – END-POINT SCALING OF GRID CELL KRO(SGCR) (SURFACTANT)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SKRORG defines the scaling parameter for the surfactant relative permeability of oil at the critical gas saturation (SGCR), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Surfactant option must be enabled by either the SURFST or SURFSTES keywords in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SKRORG	SKRORG is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling SKRORG values for each cell in the model. Repeat counts may be used, for example 50*0.850.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 8.159: SKRORG Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be scale on the relative permeability values using the SKRO, SKRORG, SKRORW, SKRW and SKRWR surfactant relative permeability grid cell arrays for the relative permeability end-point data.

Example

The example uses the EQUALS keyword to set layer one SKRORG equal to 0.750, layer two SKRORG equals 0.775, and layer three SKRORG equals 0.800.

```
--
--        ARRAY        CONSTANT      ---------- BOX ---------
--                                    I1   I2    J1   J2    K1   K2
EQUALS
          SKRORG       0.7550        1*   1*    1*   1*     1    1  / SKRORG FOR LAYER 1
          SKRORG       0.7750        1*   1*    1*   1*     2    2  / SKRORG FOR LAYER 2
          SKRORG       0.8000        1*   1*    1*   1*     3    3  / SKRORG FOR LAYER 3
/
```

8.3.290 SKRORW – END-POINT SCALING OF GRID CELL KRO(SWCR) (SURFACTANT)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SKRORW defines the scaling parameter for the surfactant relative permeability of oil at the critical water saturation (SWCR), for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Surfactant option must be enabled by either the SURFST or SURFSTES keywords in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SKRORW	SKRORW is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling SKRORW values for each cell in the model. Repeat counts may be used, for example 50*0.850			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 8.160: SKRORW Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be scale on the relative permeability values using the SKRO, SKRORG, SKRORW, SKRW and SKRWR surfactant relative permeability grid cell arrays for the relative permeability end-point data.

Example

The example defines an input box for the whole grid and for layers one to three, for layer one SKRORW is set equal to 0.750, for layer two SKRORW equals 0.775, and for layer three SKRORW equals 0.800.

```

ENDBOX
```

8.3.291 SKRW – END-POINT SCALING OF GRID CELL KRW(SW =1.0) (SURFACTANT)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SKRW defines the scaling parameter at the maximum surfactant water relative permeability value (SWU), that is for Sw = 1.0, for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword. In addition, the Surfactant option must be enabled by either the SURFST or SURFSTES keywords in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SKRW	SKRW is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling SKRW values for each cell in the model. Repeat counts may be used, for example 50*1.000.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 8.161: SKRW Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be scale on the relative permeability values using the SKRO, SKRORG, SKRORW, SKRW and SKRWR surfactant relative permeability grid cell arrays for the relative permeability end-point data.

Example

The example uses the EQUALS keyword to set SKRW for layer one equal to 0.850, layer two SKRW to 0.875, and layer three KRW to 0.900.

```
--
--        ARRAY        CONSTANT      ---------- BOX ---------
--                                   I1  I2   J1  J2   K1  K2

8.3.292 SKRWR – END-POINT SCALING OF GRID CELL KRWR(SOWCR) (SURFACTANT)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SKRWR defines the scaling parameter at the critical oil to water saturation value (SOWCR), for the surfactant water relative permeability curve, for all the cells in the model via an array. The ENDSCALE keyword in the RUNSPEC section should be activated to enable end-point scaling and the use of this keyword.In addition, the Surfactant option must be enabled by either the SURFST or SURFSTES keywords in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SKRWR	SKRWR is an array of positive real numbers which are greater than zero and less than or equal to 1.0, that are the assigned scaling SKRWR values for each cell in the model. Repeat counts may be used, for example 50*1.000.			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 8.162: SKRWR Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be scale on the relative permeability values using the SKRO, SKRORG, SKRORW, SKRW and SKRWR surfactant relative permeability grid cell arrays for the relative permeability end-point data.

Example

The first example defines an input box for the whole grid and for layers one to three, for layer one SKRWR is set equal to 0.750, for layer two SKRWR equals 0.775, and for layer three SKRWR equals 0.800.

```
--
--       DEFINE INPUT BOX FOR EDITING INPUT ARRAYS (NX=100, NY=100)

ENDBOX
```

8.3.293 SLGOF – GAS-OIL SATURATION TABLES VERSUS GAS (FORMAT TYPE 1)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SLGOF keyword defines the oil and gas relative permeability and oil-gas capillary pressure versus liquid saturation tables for when oil and gas are present in the input deck. This keyword should only be used if both oil and gas are present in the run.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SLIQ	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the liquid saturation, that is the connate water saturation (SWL) plus the oil saturation. The first entry should correspond to residual liquid, that is Swc + Sorg and the last entry should be 1.0 to correspond to a gas saturation of zero.			
		dimensionless	dimensionless	dimensionless	None
2	KRG	A columnar vector of real values that are either equal or decreasing down the column and that are greater than or equal to zero and less than or equal to one that defines the gas relative permeability..			
		dimensionless	dimensionless	dimensionless	None
3	KRO	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the oil relative permeability with respect to gas and connate water saturation. When water is active in the run, the last entry the column, that is at krog(Sg = 0), must be the same as the first entry in the corresponding SWOF table, that is at krow(So = 1 - Swco). The first value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None
4	PCOG	A columnar vector of real values that are either equal or decreasing down the column that defines the oil-gas relative capillary pressure.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.163: SLGOF Keyword Description

Example

```

         0.50000    0.00000  0.8000     0.0000
         0.80000    0.00000  0.9000     0.0000             / TABLE No. 02
```

The example defines two SLGOF tables for use when oil, gas and water are present in the run.

8.3.294 SOCRS – END-POINT SCALING GRID CELL MISCIBLE CRITICAL OIL SATURATION WITH RESPECT TO WATER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SOCRS defines the miscible critical oil saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The critical oil saturation with respect to water is defined as the maximum oil saturation for which the oil relative permeability is zero in a two-phase oil-water relative permeability table. The keyword is used with the Surfactant model to re-scale the surfactant relative permeability saturation tables allocated to a grid block by the by the SURFNUM keyword in the REGIONS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SOCRS	SOCRS is an array of real numbers assigning the critical oil saturation with respect to water values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.30			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the critical gas saturation used with the end-point scaling option. If directional end-point scaling has been activated then the SOCRSX± , SOCRSX± and SOCRSX± series of keyword should be used.
2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
3) The keyword is terminated by a "/".

Table 8.164: SOGCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOCRS, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SOCRS DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SOCRS
         300*0.200                                                    /
```

The above example defines a constant critical oil saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.295 SOF2 – OIL SATURATION TABLES WITH RESPECT TO GAS OR WATER (FORMAT TYPE 2)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SOF2 keyword defines the oil relative permeability versus oil saturation tables for when oil and gas or oil and water are present in the input deck. The keyword is also used to define the relative permeability of the miscible hydrocarbon phase in SOLVENT runs. This keyword should only be used if oil is present in the run.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SOIL	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the oil or the hydrocarbon solvent saturation. For two phase runs the oil saturation should be entered and for when the SOLVENT option has been activated in the RUNSPEC section the total hydrocarbon phase (including the solvent) should be entered, that is SOIL = So + Sg + Ss.			
		dimensionless	dimensionless	dimensionless	None
3	KRO	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the oil relative permeability with respect to gas and connate water saturation. For two phase runs the oil relative permeability should be entered and for when the SOLVENT option has been activated in the RUNSPEC section the relative permeability of the miscible hydrocarbon phase with respect to water. The last value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.165: SOF2 Keyword Description

Note this keyword should only be used for when the SOLVENT keyword in the RUNSPEC section has been activated. It should not be use for two-phase oil-water runs.

Example

```
--
--       OIL RELATIVE PERMEABILITY TABLES (SOF2)
--
SOF2
--       SOIL         KRO
--       FRAC         FRAC

            0.05      1.197e-5
            0.10      0.000191
            0.15      0.000969
            0.20      0.003065
            0.25      0.007483
            0.30      0.015517
            0.35      0.028747
            0.40      0.049041
            0.45      0.078555
            0.50      0.119730
            0.55      0.175297
            0.60      0.248272
            0.65      0.341961
            0.70      0.459956
            0.75      0.606134
            0.80      0.784664
            0.85      1.000000                          / TABLE NO. 02
```

The example defines two SOF2 tables for when oil and gas or oil and water are present in the input deck.

8.3.296 SOF3 – OIL SATURATION TABLES WITH RESPECT TO GAS AND WATER (FORMAT TYPE 2)

Description

The SOF3 keyword defines the oil relative permeability versus oil saturation tables for when oil, gas and water are present in the input deck. The keyword should only be used if oil, gas and water are present in the input deck.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SOIL	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the oil or the hydrocarbon solvent saturation. The final entry should be at the connate water saturation, that is 1- Swc.			
		dimensionless	dimensionless	dimensionless	None
3	KROW	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the oil relative permeability with respect to oil and water saturation. The first value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None
4	KROG	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the oil relative permeability with respect to oil, gas and connate water saturation. The first value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.166: SOF3 Keyword Description

Example

```
--
--       OIL RELATIVE PERMEABILITY TABLES (SOF3)
--
SOF3
--       SOIL         KRO          KROG

```

The example defines two SOF3 tables for when oil, gas and water are present in the input deck.

8.3.297 SOF32D – OIL SATURATION TABLES WITH RESPECT TO WATER AND GAS (THREE PHASE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SOF32D keyword defines the three phase oil relative permeability versus water and gas saturation tables for when oil, gas and water are present in the input deck. The keyword should only be used if oil, gas and water are present in the input deck. Normally the simulator calculates the three-phase oil relative permeabilities based on the entered two phase tables of water-oil and gas-oil, combined with the STONE1 and STONE2 keywords in the PROPS section that determine the method used to generate the thee phase oil relative permeability curves. SOF32D allows for the direct input of the three phase tables, as such the STONE1 and STONE2 keywords should not be entered if SOF32D is used in the input deck.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.298 SOGCR – END-POINT SCALING GRID CELL CRITICAL OIL SATURATION WITH RESPECT TO GAS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SOGCR defines the critical oil saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The critical oil saturation with respect to gas is defined as the maximum oil saturation for which the oil relative permeability is zero in a two-phase gas-oil relative permeability table. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SOGCR	SOGCR is an array of real numbers assigning the critical oil saturation with respect to gas values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.30 dimensionless			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the critical gas saturation used with the end-point scaling option. If directional end-point scaling has been activated then the SOGCRX± , SOGCRY± and SOGCRZ± series of keyword should be used.
2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
3) The keyword is terminated by a "/".

Table 8.167: SOGCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KRGR, KRO, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SOGCRX, SOGCRY and SOGCRZ instead of SOGCR. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SOGCRX, SOGCRX-, SOGCRY, SOGCRY-, SOGCRZ and SOGCRZ-, instead of the SOGCR keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SOGCR DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SOGCR
         300*0.200                                                    /
```

The above example defines a constant critical gas saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.299 SOMGAS – STONE1 MODEL MINIMUM OIL SATURATION VERSUS GAS SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the minimum oil saturation as a function of gas saturation for Stone's[246] first three phase oil relative permeability model as modified by Aziz and Settari[247]. If the STONE1 and STONE2 keywords are not present in the input deck then the default three phase oil relative permeability model is employed. The SOMGAS and STONE1 keywords should only be used in three phase runs containing the oil, gas and water phases. The keyword is optional.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[247] *Aziz, K. and Settari, A. Petroleum Reservoir Simulation, London, UK, Applied Science Publishers (1979), page 398.*

8.3.300 SOMWAT – STONE1 MODEL MINIMUM OIL SATURATION VERSUS WATER SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the minimum oil saturation as a function of water saturation for Stone's[248] first three phase oil relative permeability model as modified by Aziz and Settari[249]. If the STONE1 and STONE2 keywords are not present in the input deck then the default three phase oil relative permeability model is employed. The SOMWAT and STONE1 keywords should only be used in three phase runs containing the oil, gas and water phases. The keyword is optional.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[248] *Stone, H. L. "Probability Model for Estimating Three-Phase Relative Permeability," paper SPE 2116, Journal of Canadian Petroleum Technology (1973) 22, No. 2, 214-218.*

8.3.301 SORWMIS – MISCIBLE RESIDUAL OIL VERSUS WATER SATURATION FUNCTIONS

Description

SORWMIS defines the dependency between the miscible residual oil saturation and the water saturation, for when the MISCIBLE keyword in the RUNSPEC section has been activated. The keyword can only be used with the MISCIBLE option and for when the oil, water and gas phases are active in the model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWAT	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the water saturation.			
		dimensionless	dimensionless	dimensionless	None
2	SORMIS	A columnar vector of real equal or increasing down the column values that are greater than or equal to zero and less than one, that define the corresponding miscible residual oil saturation for the corresponding water saturation SWAT.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTMISC tables as declared on the MISCIBLE keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSMISC rows as declared on the MISCIBLE keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.168: SORWMIS Keyword Description

Example

```
--
--       MISCIBLE RESIDUAL OIL VERSUS WATER SATURATION TABLE
--
SORWMIS
--       SWAT       SORWMIS
--       FRAC       FRAC
--       -------    --------
          0.0000     0.0000
          0.2000     0.0000
          1.0000     0.0000                              / TABLE NO. 01
--       SWAT       SORWMIS
--       FRAC       FRAC
--       -------    --------
          0.0000     0.0000
          0.3000     0.1000
          0.7500     0.1500                              / TABLE NO. 02
```

The above example defines two miscible residual oil versus water saturation tables assuming NTMISC equals two and NSMISC is greater than or equal to three on the MISCIBLE keyword in the RUNSPEC section.

8.3.302 SOWCR – END-POINT SCALING GRID CELL CRITICAL OIL SATURATION WITH RESPECT TO WATER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SOWCR defines the critical oil saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The critical oil saturation with respect to water is defined as the maximum oil saturation for which the oil relative permeability is zero in a two-phase oil-water relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SOWCR	SOWCR is an array of real numbers assigning the critical oil saturation with respect to water values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.30			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the critical gas saturation used with the end-point scaling option. If directional end-point scaling has been activated then the SOWCRX± , SOWCRY± and SOWCRZ± series of keyword should be used.

2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.

3) The keyword is terminated by a "/".

Table 8.169: SOWCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KRGR, KRO, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SOWCRX, SOWCRY and SOWCRZ instead of SOWCR. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SOWCRX, SOWCRX-, SOWCRY, SOWCRY-, SOWCRZ and SOWCRZ-, instead of the SOWCR keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SOWCR DATA FOR ALL CELLS
–        (FOR NX x NY x NZ = 300)
--
SOWCR
         300*0.200                                                    /
```

The above example defines a constant critical oil saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.303 SPECHEAT – DEFINE THE SPECIFIC HEAT OF OIL, WATER AND GAS

Description

SPECHEAT defines the specific heat of the oil, water and gas phases for various PVT regions in the model for when the THERMAL option has been activated in the RUNSPEC section. The number of SPECHEAT vector data sets is defined by the NTPVT parameter on the TABDIMS keyword in the RUNSPEC section and the allocation of the SPECHEAT data sets to different grid blocks in the model is done via the PVTNUM keyword in the REGIONS section.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	A columnar vector of real monotonically increasing down the column values that define the temperature for the corresponding oil, water and gas specific heat values.			
		°F	°C	°C	None
2	OILSHEAT	OILSHEAT is a columnar vector of positive real numbers defining the specific heat of oil at the corresponding temperature, TEMP.			
		Btu/lb/oR	kJ/kg/K	J/gm/K	None
3	WATSHEAT	WATSHEAT is a columnar vector of positive real numbers defining the specific heat of water at the corresponding temperature, TEMP.			
		Btu/lb/oR	kJ/kg/K	J/gm/K	None
4	GASSHEAT	GASHEAT is a columnar vector of positive real numbers defining the specific heat of gas at the corresponding temperature, TEMP.			
		Btu/lb/oR	kJ/kg/K	J/gm/K	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.170: SPECHEAT Keyword Description

See also the SPECROCK keyword to define the reservoir rock specific heat.

Example

The example below defines three fluid phases specific heat versus temperature tables assuming NTPVT equals three and NPPVT is greater than or equal to two on the TABDIMS keyword in the RUNSPEC section.

```
--
--       SPECIFIC HEAT OF OIL, WATER AND GAS TABLE
--
SPECHEAT
--       TEMP       SPECHEAT   SPECHEAT   SPECHEAT
--                   OIL        WATER      GAS
--       -------    --------   --------   --------
           0.000     0.5000     1.5000     0.5000
         250.000     0.5000     1.5000     0.5000          / TABLE NO. 01
--       TEMP       SPECHEAT   SPECHEAT   SPECHEAT
--                   OIL        WATER      GAS
--       -------    --------   --------   --------
           0.000     0.5500     1.5000     0.5000
         260.000     0.5500     1.5000     0.5000          / TABLE NO. 02
--       TEMP       SPECHEAT   SPECHEAT   SPECHEAT
--                   OIL        WATER      GAS
--       -------    --------   --------   --------
           0.000     0.5500     1.5500     0.5000
         270.000     0.6000     1.5500     0.5000          / TABLE NO. 03
```

There is no terminating "/" for this keyword.

8.3.304 SPECROCK – DEFINE THE SPECIFIC HEAT OF THE RESERVOIR ROCK

Description

SPECROCK defines the specific heat of the reservoir rock for various PVT regions in the model for when the THERMAL option has been activated in the RUNSPEC section. The number of SPECROCK vector data sets is defined by the NTSFUN parameter on the TABDIMS keyword in the RUNSPEC section and the allocation of the SPECROCK data sets to different grid blocks in the model is done via the SATNUM keyword in the REGIONS section.

This keyword can only be used if OPM's Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	A columnar vector of real monotonically increasing down the column values that define the temperature for the corresponding rock specific heat values.			
		°F	°C	°C	None
2	ROCKHEAT	ROCKHEAT is a columnar vector of positive real numbers defining the specific heat of the rock at the corresponding temperature, TEMP.			
		Btu/ft3/oR	kJ/m3/K	J/cc/K	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.171: SPECROCK Keyword Description

See also the SPECHEAT keyword to define the specific heat relationships for the oil, water and gas phases.

Example

The example below defines three rock specific heat versus temperature tables assuming NTSFUN equals three and NSSFUN is greater than or equal to two on the TABDIMS keyword in the RUNSPEC section.

```
--
--        SPECIFIC HEAT OF ROCK
--
SPECROCK
--        TEMP        SPECHEAT
--                    ROCK
--        -------     --------
            0.000      20.000
          250.000      20.000                                / TABLE NO. 01
--        -------     --------
            0.000      21.000
          260.000      21.000                                / TABLE NO. 02
--        -------     --------
            0.000      23.000
          270.000      23.000                                / TABLE NO. 03
```

There is no terminating "/" for this keyword.

8.3.305 SSFN – SOLVENT AND GAS RELATIVE PERMEABILITY TABLES

Description

The SSFN keyword defines the miscible normalized relative permeability tables for when the SOLVENT option has been activated in the RUNSPEC section using the respective keyword. The SOLVENT keyword results in a four component model (oil, water and gas, plus a solvent). This keyword should only be used if the SOLVENT option has been activated.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SGAS	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the gas plus solvent saturation ration which is defined as either: $\frac{S_g}{(S_g + S_s)}$ or $\frac{S_s}{(S_g + S_s)}$ Where Sg is the gas saturation and Ss is the solvent saturation.			
		dimensionless	dimensionless	dimensionless	None
2	KRGt	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the gas relative permeability. The resulting gas relative permeability is calculated from: $k_{rg} = k_{rgt}(S_g + S_s)k_{rg}^{t}$ where krg^t is the data in this column and krgt is the gas relative permeability from the SGFN keyword.			
		dimensionless	dimensionless	dimensionless	None
3	KRSt	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the solvent relative permeability. The resulting solvent relative permeability is calculated from: $k_{rs} = k_{rgt}(S_g + S_s)k_{rs}^{t}$ where krS^t is the data in this column and krgt is the gas relative permeability from the SGFN keyword.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.172: SSFN Keyword Description

Example

```
--
--        SOLVENT RELATIVE PERMEABILITY TABLES
--
SSFN
--        SGAS        KRGT          KRST
--        FRAC
--        --------  --------      --------
           0.0000    0.0000        0.0000
           1.0000    1.0000        1.0000                    / TABLE NO. 01
--        --------  --------      --------
           0.0000    0.0000        0.0000
           0.2000    0.2000        0.3000
           0.4000    0.3000        0.5000
           0.6000    0.4000        0.7000
           0.8000    0.5000        0.7500
           1.0000    1.0000        1.0000                    / TABLE NO. 02
```

The above example defines two SSFN tables for use with the SOLVENT option.

8.3.306 SSGCR – END-POINT SCALING GRID CELL SURFACTANT CRITICAL GAS SATURATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SSGCR defines the surfactant critical gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword and the surfactant phase has been activated by the SURFACT keyword in the RUNSPEC section. The critical gas saturation is defined as the maximum gas saturation for which the gas relative permeability is zero in a two-phase relative permeability table. SSGCR is used to scale the surfactant oil relative permeability to gas data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SSGCR	SSGCR is an array of real numbers assigning the surfactant critical gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.03			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
2) The keyword is terminated by a "/".

Table 8.173: SSGCR Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SSWL, SSWCR, SSWU, SSGL, SSGCR, SSGU, SSOWCR, and SSOGCR saturation grid arrays for the saturation end-points, and the SKRG, SKROG, SKROW and SKRW relative permeability grid cell arrays for the relative permeability end-point data.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SSGCR DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SSGCR
         300*0.050                                                    /
```

The above example defines a constant surfactant critical oil saturation with respect to gas of 0.05 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.307 SSGL – END-POINT SCALING GRID CELL SURFACTANT CONNATE GAS SATURATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SSGL defines the surfactant connate gas saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword and the surfactant phase has been activated by the SURFACT keyword in the RUNSPEC section. The connate gas saturation is defined as the minimum gas saturation in a two-phase gas relative permeability table. SSGL is used to scale the surfactant oil and water relative permeability data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SSGL	SSGL is an array of real numbers assigning the surfactant connate gas saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.03			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
2) The keyword is terminated by a "/".

Table 8.174: SSGL Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SSWL, SSWCR, SSWU, SSGL, SSGCR, SSGU, SSOWCR, and SSOGCR saturation grid arrays for the saturation end-points, and the SKRG, SKROG, SKROW and SKRW relative permeability grid cell arrays for the relative permeability end-point data.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SSGL DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SSGL
         300*0.030                                                    /
```

The above example defines a constant surfactant connate gas saturation of 0.03 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.308 SSOGCR – END-POINT SCALING GRID CELL SURFACTANT CRITICAL OIL SATURATION WITH RESPECT TO GAS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SSOGCR defines the surfactant critical oil saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword and the surfactant phase has been activated by the SURFACT keyword in the RUNSPEC section. The critical oil saturation with respect to gas is defined as the maximum oil saturation for which the oil relative permeability is zero in a two-phase gas-oil relative permeability table. SSOGCR scales the surfactant oil relative permeability to gas data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SSOGCR	SSOGCR is an array of real numbers assigning the surfactant critical oil saturation with respect to gas values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.30 dimensionless			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
2) The keyword is terminated by a "/".

Table 8.175: SSOGCR Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SSWL, SSWCR, SSWU, SSGL, SSGCR, SSGU, SSOWCR, and SSOGCR saturation grid arrays for the saturation end-points, and the SKRG, SKROG, SKROW and SKRW relative permeability grid cell arrays for the relative permeability end-point data.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SSOGCR DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SSOGCR
         300*0.200                                                    /
```

The above example defines a surfactant constant critical oil saturation with respect to gas of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.309 SSOWCR – END-POINT SCALING GRID CELL SURFACTANT CRITICAL OIL SATURATION WITH RESPECT TO WATER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SSOWCR defines the surfactant critical oil saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword and the surfactant phase has been activated by the SURFACT keyword in the RUNSPEC section. The critical oil saturation with respect to water is defined as the maximum oil saturation for which the oil relative permeability is zero in a two-phase oil-water relative permeability table. SSOWCR scales the surfactant oil relative permeability to water data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SSOWCR	SSOWCR is an array of real numbers assigning the surfactant critical oil saturation with respect to water values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.30			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
2) The keyword is terminated by a "/".

Table 8.176: SSOWCR Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SSWL, SSWCR, SSWU, SSGL, SSGCR, SSGU, SSOWCR, and SSOGCR saturation grid arrays for the saturation end-points, and the SKRG, SKROG, SKROW and SKRW relative permeability grid cell arrays for the relative permeability end-point data.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SSOWCR DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SSOWCR
         300*0.200                                                    /
```

The above example defines a constant critical oil saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.310 SSWCR – END-POINT SCALING GRID CELL CRITICAL WATER SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SSWCR defines the surfactant critical water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword and the surfactant phase has been activated by the SURFACT keyword in the RUNSPEC section. The critical water saturation is defined as the maximum water saturation for which the water relative permeability is zero in a two-phase relative permeability table. SSWCR scales the surfactant water relative permeability data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SSWCR	SSWCR is an array of real numbers assigning the surfactant critical water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.20			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
2) The keyword is terminated by a "/".

Table 8.177: SSWCR Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SSWL, SSWCR, SSWU, SSGL, SSGCR, SSGU, SSOWCR, and SSOGCR saturation grid arrays for the saturation end-points, and the SKRG, SKROG, SKROW and SKRW relative permeability grid cell arrays for the relative permeability end-point data.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SSWCR DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SSWCR
         300*0.200                                                    /
```

The above example defines a constant surfactant critical water saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.311 SSWL – END-POINT SCALING GRID CELL SURFACTANT CONNATE WATER SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SSWL defines the surfactant connate water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword and the surfactant phase has been activated by the SURFACT keyword in the RUNSPEC section. The connate water saturation is defined as the minimum water saturation in a two-phase water relative permeability table. SSWL scales the surfactant oil relative permeability to water and gas data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SSWL	SSWL is an array of real numbers assigning the connate water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.15			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
2) The keyword is terminated by a "/".

Table 8.178: SSWL Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SSWL, SSWCR, SSWU, SSGL, SSGCR, SSGU, SSOWCR, and SSOGCR saturation grid arrays for the saturation end-points, and the SKRG, SKROG, SKROW and SKRW relative permeability grid cell arrays for the relative permeability end-point data.

Example

```
--
--        DEFINE GRID BLOCK END-POINT SSWL DATA FOR ALL CELLS
--        (FOR NX x NY x NZ = 300)
--
SSWL
          300*0.150                                                    /
```

The above example defines a constant surfactant connate water saturation of 0.15 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.312 SSWU – END-POINT SCALING GRID CELL SURFACTANT MAXIMUM WATER SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SSWU defines the surfactant maximum water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword and the surfactant phase has been activated by the SURFACT keyword in the RUNSPEC section. The maximum water saturation is defined as the maximum water saturation in a two-phase water relative permeability table. SSWU scales the surfactant water relative permeability data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SSWU	SSWU is an array of real numbers assigning the surfactant maximum water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.70			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
2) The keyword is terminated by a "/".

Table 8.179: SSWU Keyword Description

End-point scaling allows the entered surfactant relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SSWL, SSWCR, SSWU, SSGL, SSGCR, SSGU, SSOWCR, and SSOGCR saturation grid arrays for the saturation end-points, and the SKRG, SKROG, SKROW and SKRW relative permeability grid cell arrays for the relative permeability end-point data.

Example

```
--
--        DEFINE GRID BLOCK END-POINT SSWU DATA FOR ALL CELLS
--        (FOR NX x NY x NZ = 300)
--
SSWU
          300*0.700                                                    /
```

The above example defines a constant surfactant connate gas saturation of 0.70 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.313 STOG DEFINE CAPILLARY PRESSURE OIL-GAS SURFACE TENSION VERSUS PRESSURE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The STOG keyword defines capillary pressure oil-gas surface tension versus pressure tables used in adjusting the pressure independent capillary pressure vectors in the SGFN, SGOF or SLGOF saturation tables, entered by their respective keywords in the PROPS section. The SATOPTS keyword in the RUNSPEC section should state the SURFTENS character string to activate the Capillary Pressure Surface Tension Pressure Dependency option. If the STOG keyword is not supplied then no capillary pressure surface tension pressure scaling will occur and the capillary pressure values on the SGFN, SGOF or SLGOF saturation tables will be used directly.

Capillary pressure surface tension pressure scaling can also be used with multi-segment wells, but this facility has not been incorporated in OPM Flow's multi-segment well implementation.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.314 STONE – ACTIVATE STONE'S SECOND THREE PHASE OIL RELATIVE PERMEABILITY MODEL (ALIAS FOR STONE2)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword is an alias for STONE2 keyword that activates Stone's[250] second three phase oil relative permeability model as modified by Aziz and Settari[251]. If the STONE, STONE1 and STONE2 keywords are not present in the input deck then the default three phase oil relative permeability model is employed. The STONE keyword should only be used in three phase runs containing the oil, gas and water phases.

There is no data required for this keyword.

Example

```
--
--       ACTIVATE STONE'S SECOND THREE PHASE RELATIVE PERMEABILITY MODEL
--
STONE
```

The above example switches on the Modified Stone three phase relative permeability model.

[250] *Stone, H. L. "Estimation of Three-Phase Relative Permeability and Residual Oil Data," Journal of Canadian Petroleum Technology (1973) 12, No. 4, 53-61.*

[251] *Aziz, K. and Settari, A. Petroleum Reservoir Simulation, London, UK, Applied Science Publishers (1979), page 398.*

8.3.315 STONE1 – ACTIVATE STONE'S FIRST THREE PHASE OIL RELATIVE PERMEABILITY MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates Stone's[252] first three phase oil relative permeability model as modified by Aziz and Settari[253]. If the STONE1 and STONE2 keywords are not present in the input deck then the default three phase oil relative permeability model is employed. The STONE1 keyword should only be used in three phase runs containing the oil, gas and water phases.

There is no data required for this keyword.

Example

```
--
--       ACTIVATE STONE'S FIRST THREE PHASE RELATIVE PERMEABILITY MODEL
--
STONE1
```

The above example switches on the Modified Stone three phase relative permeability model.

[252] *Stone, H. L. "Probability Model for Estimating Three-Phase Relative Permeability," paper SPE 2116, Journal of Canadian Petroleum Technology (1973) 22, No. 2, 214-218.*

[253] *Aziz, K. and Settari, A. Petroleum Reservoir Simulation, London, UK, Applied Science Publishers (1979), page 398.*

8.3.316 STONE1EX – DEFINE STONE'S FIRST THREE PHASE OIL RELATIVE PERMEABILITY PARAMETER

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the exponent used in Stone's[254] first three phase oil relative permeability model as modified by Aziz and Settari[255]. The STONE1EX keyword should only be used in three phase runs containing the oil, gas and water phases and when the STONE1 keyword in the PROPS section has been used to activate Stone's first three phase oil relative permeability model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	STONEPAR1	A real positive value that defines the exponent to be used in the Modified Stone first three phase oil relative permeability model.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTSFUN records as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each record must contain only one value and is terminated by a "/"
3) There is no "/" terminator for the keyword.

Table 8.180: STONE1EX Keyword Description

If the STONE, STONE1 and STONE2 keywords are not present in the input deck then the default three phase oil relative permeability model is employed.

Example

Given NTSFUN equals five on the TABDIMS keyword in the RUNSPEC section, then:

```
--
--       DEFINE STONE'S FIRST THREE PHASE RELATIVE PERMEABILITY MODEL PARAMETER
--
STONE1EX
         1.000                                          / SATURATION TABLE NO. 01
         1.000                                          / SATURATION TABLE NO. 02
         2.000                                          / SATURATION TABLE NO. 03
         1.000                                          / SATURATION TABLE NO. 04
         3.000                                          / SATURATION TABLE NO. 05
```

Defines the exponents to be used in the Modified Stone first three phase oil relative permeability model, for each of the five saturation tables.

[254] *Stone, H. L. "Probability Model for Estimating Three-Phase Relative Permeability," paper SPE 2116, Journal of Canadian Petroleum Technology (1973) 22, No. 2, 214-218.*

[255] *Aziz, K. and Settari, A. Petroleum Reservoir Simulation, London, UK, Applied Science Publishers (1979), page 398.*

8.3.317 STONE2 – ACTIVATE STONE'S SECOND THREE PHASE OIL RELATIVE PERMEABILITY MODEL

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword activates Stone's[256] second three phase oil relative permeability model as modified by Aziz and Settari[257]. If the STONE, STONE1 and STONE2 keywords are not present in the input deck then the default three phase oil relative permeability model is employed. The STONE2 keyword should only be used in three phase runs containing the oil, gas and water phases.

There is no data required for this keyword.

Example

```
--
--       ACTIVATE STONE'S SECOND THREE PHASE RELATIVE PERMEABILITY MODEL
--
STONE2
```

The above example switches on the Modified Stone three phase relative permeability model.

[256] *Stone, H. L. "Estimation of Three-Phase Relative Permeability and Residual Oil Data," Journal of Canadian Petroleum Technology (1973) 12, No. 4, 53-61.*

[257] *Aziz, K. and Settari, A. Petroleum Reservoir Simulation, London, UK, Applied Science Publishers (1979), page 398.*

8.3.318 STOW DEFINE CAPILLARY PRESSURE OIL-WATER SURFACE TENSION VERSUS PRESSURE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The STOW keyword defines capillary pressure oil-water surface tension versus pressure tables used in adjusting the pressure independent capillary pressure vectors in the SWFN or SWOF saturation tables, entered by their respective keywords in the PROPS section. The SATOPTS keyword in the RUNSPEC section should state the SURFTENS character string to activate the Capillary Pressure Surface Tension Pressure Dependency option. If the STOW keyword is not supplied then no capillary pressure surface tension pressure scaling will occur and the capillary pressure values on the SWFN or SWOF saturation tables will be used directly.

Capillary pressure surface tension pressure scaling can also be used with multi-segment wells, but this facility has not been incorporated in OPM Flow's multi-segment well implementation.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.319 STWG DEFINE CAPILLARY PRESSURE WATER-GAS SURFACE TENSION VERSUS PRESSURE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The STWG keyword defines capillary pressure water-gas surface tension versus pressure tables for use with multi-segment wells. This facility has not been incorporated in OPM Flow's multi-segment well implementation. Note that STWG is not required for Capillary Pressure Surface Tension Pressure Dependency option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.320 SURFADDW – DEFINED SURFACTANT ADSORBED CONCENTRATION VERSUS WETTABILITY FRACTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SURFADDW defines tables of surfactant adsorbed concentration versus wettability fraction for when the SURFACTW keyword in the RUNSPEC section as been declared to activate the surfactant phase with changing wettability. The tables consists of columnar vectors of adsorbed surfactant concentration versus a wettability fraction that indicates the fraction of phase wettability. Here, a wettability fraction of zero indicates a 100% water wet rock resulting in the SURFWNUM allocated saturation tables being used, and a value of one meaning 100% oil wet rock, with the SATNUM allocated saturations tables being employed. Both the SURFWNUM and SATNUM keywords are in the REGIONS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.321 SURFADS - DEFINE SURFACTANT ROCK ADSORPTION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SURFADS keyword defines the rock surfactant adsorption tables for when the surfactant option has been activated by the SURFACT keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SURCON	A columnar vector of real monotonically increasing down the column values that defines the surfactant concentration in the solution surrounding the rock. The first entry should be zero to define a no surfactant concentration.			
		lb/stb	kg/sm^3	gm/scc	None
2	SURRATIO	A columnar vector of real increasing down the column values that defines the mass of adsorbed surfactant per unit mass of rock of the saturated concentration of surfactant adsorbed by the rock. The first entry should be zero to define a zero ratio of surfactant concentration.			
		lb/lb	kg/kg	gm/gm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.181: SURFADS Keyword Description

See also the ADSORP keyword in the PROPS section that employs adsorption functions, as oppose to adsorption tables, to define rock surfactant adsorption behavior.

Example

```
--
--       SURFACTANT ROCK ADSORPTION TABLE
--
SURFADS
--       SURF       SURF
--       SURCON     SURRATIO
--       -------    --------
             0.0     0.00000
             2.0     0.00003
             4.0     0.00005
             6.0     0.00007
             8.0     0.00009
            10.0     0.00011
            12.0     0.00012
            14.0     0.00015                              / TABLE NO. 01
--       SURF       SURF
--       SURCON     SURRATIO
--       -------    --------
             0.0     0.00000
             3.0     0.00004
             5.0     0.00006
             7.0     0.00008
             8.0     0.00009
            10.0     0.00011                              / TABLE NO. 02
```

The above example defines two surfactant rock adsorption tables assuming NTSFUN equals two and NSSFUN is greater than or equal to eight on the TABDIMS keyword in the RUNSPEC section.

There is no terminating "/" for this keyword.

8.3.322 SURFCAPD – CAPILLARY NUMBER VERSUS MISCIBILITY TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SURFCAPD keyword defines the relationship between the log of the capillary number and the level of miscibility, for when the Surfactant option has been activated by the SURFACT keyword in the RUNSPEC section. A value of zero for the level of miscibility means fully immiscible conditions and consequently a value of one implies fully miscible conditions.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.323 SURFESAL – DEFINE SURFACTANT EFFECTIVE SALINITY COEFFICIENT

Description

This keyword, SURFESAL, defines the surfactant effective salinity coefficient as well as enabling the effective salinity calculation for surfactant adsorption. The keyword should only be used if the BRINE keyword has been declared to activate the brine phase, the ECLMC keyword to enable the Multi-Component Brine model, and the SURFACT keyword has been used to activate the surfact phase. All three keywords are in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.324 SURFROCK - DEFINE SURFACTANT-ROCK PROPERTIES

Description

The SURFROCK keyword defines rock properties for when the Surfactant option has been activated by the SURFACTANT keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	ADINDX	A positive integer of 1 or 2 that defines the surfactant desorption option. 1) then surfactant desorption may occur by retracing the surfactant adsorption isotherm when the local surfactant concentration in the solution decreases. 2) then no surfactant desorption may occur.			
		dimensionless 1	dimensionless 1	dimensionless 1	Defined
2	DENSITY	A real value that defines the rock in-situ density, that is at reservoir conditions.			
		lb/rtb	kg/rm^3	gm/rcc	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section, for each surfactant flooding region. There should be only one row per table.

2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.182: SURFROCK Keyword Description

Example

```
--
--       SURFACTANT-ROCK PROPERTIES
--
SURFROCK
--       DESORP   INSITU
--       OPTN     DENSITY
--       ------   -------
           1      1800.0                          / TABLE NO. 01
           2      1980.0                          / TABLE NO. 02
           1      2005.0                          / TABLE NO. 03
```

The above example defines three surfactant-rock tables, based on the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section being equal to three.

There is no terminating "/" for this keyword.

8.3.325 SURFST - SURFACTANT WATER-OIL SURFACE TENSION VERSUS SURFACTANT CONCENTRATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SURFST keyword defines surfactant water-oil surface tension versus surfactant concentration in the water phase tables, used in adjusting the pressure independent capillary pressure vectors in the SWFN or SWOF saturation tables, entered by their respective keywords in the PROPS section. SURFST is also used to adjust the relative permeability curves on the aforementioned tables via the capillary number. The Surfactant option must have been activated by the SURFACTANT keyword in the RUNSPEC section to use this keyword and either this keyword or the SURFSTES keyword, also in the PROPS section, is obligatory in this case.

See also the SURFSTES that defines the surfactant water-oil surface tension as a function of surfactant concentration in the water phase and salt concentration or the effective salinity.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.326 SURFSTES - SURFACTANT WATER-OIL SURFACE TENSION VERSUS SURFACTANT AND SALT CONCENTRATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SURFSTES keyword defines surfactant water-oil surface tension versus surfactant concentration in the water phase tables, used in adjusting the pressure independent capillary pressure vectors in the SWFN or SWOF saturation tables, entered by their respective keywords in the PROPS section. SURFSTES is also used to adjust the relative permeability curves on the aforementioned tables via the capillary number. The Surfactant option must have been activated by the SURFACTANT keyword in the RUNSPEC section to use this keyword and either this keyword or the SURFST keyword, also in the PROPS section, is obligatory in this case. In addition, the BRINE keyword in the RUNSPEC section must be activated and the ESSNODE keyword in the PROPS section must be used to define the salt concentration or the effective salinity.

See also the SURFSTS that defines the surfactant water-oil surface tension as a function of surfactant concentration in the water phase only.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.327 SURFVISC – SURFACTANT SOLUTION VISCOSITY VERSUS CONCENTRATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SURFSVISC defines the surfactant viscosity relationship of solution water viscosity with respect to increasing surfactant concentration within a grid block. The surfactant option must be activated by the SURFACT keyword in the RUNSPEC section in order to use this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SURFCON	A columnar vector of real monotonically increasing down the column values that defines the surfactant concentration in the solution surrounding the rock. The first entry should be zero to define a no surfactant concentration.			
		lb/stb	kg/sm^3	gm/scc	None
2	SURFVISC	A columnar vector of real positive values that defines the solution water viscosity of the solution for the given SURFCON entry at the reference pressure value, PRES, entered on the PVTW keyword in the PROPS section.			
		cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.183: SURFVISC Keyword Description

Example

```
--
--       SURFACTANT SOLUTION WATER VISCOSITY TABLES
--
SURFVISC
--       SURF          VISCOSITY
--       SURFCON       SURFVISC
--       --------     -----------
          0.0000       0.3500
          0.0100       0.3900
          0.0200       0.4200
          0.0300       0.4300                          / TABLE NO. 01
```

```
--       SURF          VISCOSITY
--       SURFCON       VISFAC
--       --------     ---------
          0.0000        1.000
          0.0003       10.000
          0.0005       20.000
          0.0007       40.000
          0.0009       45.000
          0.0011       55.000                          / TABLE NO. 02
```

The example defines two surfactant viscosity scaling factor tables, based on the NTPVT variable on the TABDIMS keyword in the RUNSPEC section being equal to two and NPPVT variable on the same keyword being greater than or equal to six.

8.3.328 SWATINIT – DEFINE THE INITIAL WATER SATURATION ARRAY FOR CAPILLARY PRESSURE SCALING

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SWATINIT defines the initial water saturation for all the cells in the model via an array. The keyword can be used with all grid types. SWATINIT is used to initialize the model by setting each grid block's initial water saturation ("Sw"). If the array is present in the input deck, then OPM Flow will re-scale the water-oil capillary pressure curves entered via the SWFN saturation functions in the PROPS section, so that the resulting initialized Sw matches the values in the SWATINIT array.

Normally the SWATINIT array is generated in the static earth model when calculating the hydrocarbons in-place. volumes using Saturation Height Functions ("SHF") derived from capillary pressure functions. Static earth models do not directly use capillary pressure in these type of calculations as individual cell pressures are not required. There is therefore some potential for inconsistencies to arise between the two sets of formulations. This is normally manifested by extreme scaling in the scaled capillary pressure values calculated by the simulator. If this is the case then the PPCWMAX keyword can be used to set a maximum scaled capillary pressure value. Note that as large values of scaled capillary pressures can result in numerical issues, a more technically sound approach would be to resolve these inconsistencies before continuing with the model build.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWATINIT	SWATINIT is an array of real positive numbers that are greater than or equal to zero and less than or equal to one, that define the initial water saturation values to each cell in the model. Repeat counts may be used, for example 3000*0.15			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.

2) The keyword is terminated by a "/".

Table 8.184: SWATINIT Keyword Description

See also the PPCWMAX to control the re-scaling of the capillary pressure entries on the SWFN saturation function keyword in the PROPS section.

Example

```
--
--        DEFINE GRID BLOCK INITIAL SW DATA FOR ALL CELLS
--        (BASED ON NX x NY x NZ = 300)
--
SWATINIT
          300*0.300                                                    /
```

The above example defines a constant initial water saturation of 0.300 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.329 SWCR – END-POINT SCALING GRID CELL CRITICAL WATER SATURATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SWCR defines the critical water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The critical water saturation is defined as the maximum water saturation for which the water relative permeability is zero in a two-phase relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWCR	SWCR is an array of real numbers assigning the critical water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.20			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the critical water saturation used with the end-point scaling option. If directional end-point scaling has been activated then the SWCRX± , SWCRY± and SWCRZ± series of keyword should be used.

2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.

3) The keyword is terminated by a "/".

Table 8.185: SWCR Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KRGR, KRO, KRORG, KRORW, KRW and KRWR relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWCRX, SWCRY and SWCRZ instead of SWCR. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWCRX, SWCRX-, SWCRY, SWCRY-, SWCRZ and SWCRZ-, instead of the SWCR keyword.

Example

```
--
--        DEFINE GRID BLOCK END-POINT SWCR DATA FOR ALL CELLS
--        (FOR NX x NY x NZ = 300)
--
SWCR
          300*0.200                                                    /
```

The above example defines a constant critical water saturation of 0.20 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.330 SWF32D – WATER SATURATION TABLES WITH RESPECT TO OIL AND GAS (THREE PHASE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SWF32D keyword defines the three phase water relative permeability versus oil and gas saturation tables for when oil, gas and water are present in the input deck. The keyword should only be used if oil, gas and water are present in the input deck. Normally the simulator calculates the three-phase oil relative permeabilities based on the entered two phase tables of water-oil and gas-oil, combined with the STONE1 and STONE2 keywords in the PROPS section that determine the method used to generate the thee phase water relative permeability curves. SWF32D allows for the direct input of the three phase tables, as such the STONE1 and STONE2 keywords should not be entered if SWF32D is used in the input deck.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.331 SWFN – WATER SATURATION TABLES (FORMAT TYPE 2)

Description

The SWFN keyword defines the water relative permeability and water-oil capillary pressure data versus water saturation tables for when water is present in the input deck. This keyword should only be used if water is present in the run.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWAT	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the water saturation.			
		dimensionless	dimensionless	dimensionless	None
2	KRW	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the water relative permeability with respect to gas saturation. The first value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None
3	PCWO	A columnar vector of real values that are either equal or increasing down the column that defines the water-oil relative capillary pressure. If the SWATINIT keyword has been used to initialize the model then columnar vector has to be strictly monotonically increasing.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Items (2) and (3) may be defaulted, in which case linear interpolation or constant extrapolation will be used to calculate the missing values. At least two values must be entered for item (2), and at least one value must be entered for item (3).
4) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.186: SWFN Keyword Description

Example

```
--
--       WATER RELATIVE PERMEABILITY TABLES (SWFN)
--
SWFN
--       SWAT       KRW        PCOW
--       FRAC       FRAC       PSIA

            0.30     0.00050     0.0
            0.35     0.00160     0.0
            0.40     0.00390     0.0
            0.45     0.00810     0.0
            0.50     0.01500     0.0
            0.55     0.02560     0.0
            0.60     0.04100     0.0
            0.65     0.06250     0.0
            0.70     0.09150     0.0
            0.75     0.12960     0.0
            0.80     0.17850     0.0
            0.85     0.24010     0.0
            0.90     0.31640     0.0
            0.95     0.40960     0.0
            1.00     0.52200     0.0                    / TABLE NO. 1
--       --------   --------   -------
            0.15     0.00000     0.0
            0.20     6.25e-6     0.0
            0.25     0.00010     0.0
            0.30     0.00050     0.0
            0.35     0.00160     0.0
            0.40     0.00390     0.0
            0.45     0.00810     0.0
            0.50     0.01500     0.0
            0.55     0.02560     0.0
            0.60     0.04100     0.0
            0.65     0.06250     0.0
            0.70     0.09150     0.0
            0.75     0.12960     0.0
            0.80     0.17850     0.0
            0.85     0.24010     0.0
            0.90     0.31640     0.0
            0.95     0.40960     0.0
            1.00     0.52200     0.0                    / TABLE NO. 2
```

The example defines two SWFN tables for use when water is present in the run.

8.3.332 SWL – END-POINT SCALING GRID CELL CONNATE WATER SATURATION

Description

SWL defines the connate water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The connate water saturation is defined as the minimum water saturation in a two-phase water relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWL	SWL is an array of real numbers assigning the connate water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.15			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the connate gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the SWLX± , SWLY± and SWZ± series of keyword should be used.
2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
3) The keyword is terminated by a "/".

Table 8.187: SWL Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWLX, SWLY and SWLZ instead of SWL. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWLX, SWLX-, SWLY, SWLY-, SWLZ and SWLZ-, instead of the SWL keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SWL DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SWL
         300*0.150                                                    /
```

The above example defines a constant connate water saturation of 0.15 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.333 SWLPC – END-POINT SCALING GRID CELL CAPILLARY PRESSURE CONNATE WATER SATURATIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

SWLPC defines the connate water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The connate water saturation is defined as the minimum water saturation in a two-phase water relative permeability table. The keyword only applies the scaling to the drainage capillary pressures tables, unlike the SWL keyword that applies the scaling to both the capillary pressure and relative permeability tables. The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWLPC	SWLPC is an array of real numbers assigning the connate water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. If SWLPC is omitted from the input deck the values will be defaulted to those on the SWL series of keywords. If the SWL series of keywords are missing from the input deck then the values are taken from the cell allocated capillary pressure table. Repeat counts may be used, for example 30*0.03			Taken from SGL or from the cell allocated capillary pressure table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the connate gas saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the SWLX± , SWLY± and SWZ± series of keyword should be used.

2) The keyword is terminated by a "/".

Table 8.188: SWLPC Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWLX, SWLY and SWLZ instead of SWL or SWLPC. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWLX, SWLX-, SWLY, SWLY-, SWLZ and SWLZ-, instead of the SWL or SWLPC keywords.

Missing Some Functionality - Use with Caution.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SWLPC DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SWLPC
         300*0.150                                                              /
```

The above example defines a constant connate water saturation of 0.15 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.334 SWOF – WATER-OIL SATURATION TABLES (FORMAT TYPE 1)

Description

The SWOF keyword defines the water and oil relative permeability and water-oil capillary pressure data versus water saturation tables for when water and oil are present in the input deck. This keyword should only be used if water and oil are present in the run.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWAT	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the water saturation. The first entry is the connate water saturation Swc and the last entry should be 1.0.			
		dimensionless	dimensionless	dimensionless	None
2	KRW	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the water relative permeability with respect to gas saturation. The first value in the column should be zero.			
		dimensionless	dimensionless	dimensionless	None
3	KRO	A columnar vector of real values that are either equal or decreasing down the column and that are greater than or equal to zero and less than or equal to one that defines the oil relative permeability with respect to oil and water saturation. When gas is active in the run, the first entry the column, that is at krow(So = 1-Swc), must be the same as the first entry in the corresponding SGOF or SLGOF table, that is at krog(Sg = 0). The first value in the column should be one.			
		dimensionless	dimensionless	dimensionless	None
4	PCWO	A columnar vector of real values that are either equal or decreasing down the column that defines the water-oil relative capillary pressure. If the SWATINIT keyword has been used to initialize the model then columnar vector has to be strictly monotonically increasing.			
		psia	bars	atm	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.189: SWOF Keyword Description

Example

The following example is based on NTSFUN equals two on the TABDIMS keyword in the RUNSPEC section.

```
--
--       WATER-OIL RELATIVE PERMEABILITY TABLES (SWOF)
--
SWOF
--       SWAT       KRW       KROW      PCOW
--       FRAC                           PSIA
--       --------   --------  -------   -------

```

The example defines two SWOF tables for use when water and oil are present in the run. In the tables the water-oil capillary pressure data has been set to zero.

8.3.335 SWOFLET – WATER-OIL LET RELATIVE PERMEABILITY FUNCTIONS

Description

SWOFLET defines the relative permeability and capillary pressure parameters for the water-oil LET family of models. Both the oil and water phases should be made active in the model via the OIL and WATER keywords in the RUNSPEC section. See section *8.2.6Saturation Table Generation - LET Functions* and Lomeland et al.[258],[259] [260] and [261] for further information on the model.

The keyword is used as a replacement for the SWOF keyword for three-phase oil-gas-water systems, and the LET series of keywords cannot be combined with the standard set of relative permeability keywords.

Note

This is an OPM Flow specific keyword and will therefore cause an error in the commercial simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWL	SWL is a real positive number less than one, that defines the connate water saturation, that is the smallest water saturation in the LET function.			0.0
		dimensionless	dimensionless	dimensionless	
2	SWCR	SWCR is a real positive number greater than or equal to SWL and less than one, that defines the critical water saturation, that is the largest water saturation for which the water relative permeability is zero, Swirr in equations.			0.0
		dimensionless	dimensionless	dimensionless	
3	LWAT	LWAT is a real positive number that defines the LET Lower empirical parameter Lw for the water phase with the associated oil phase in the LET relative permeability equations.			1.0
		dimensionless	dimensionless	dimensionless	
4	EWAT	EWAT is a real positive number that defines the LET Elevation empirical parameter Ew for the water phase with the associated oil phase in the LET relative permeability equations.			1.0
		dimensionless	dimensionless	dimensionless

No.	Name	Description			Default
		Field	Metric	Laboratory	
5	TWAT	TWAT is a real positive number that defines the LET Top empirical parameter Tw for the water phase with the associated oil phase in the LET relative permeability equations.			1.0
		dimensionless	dimensionless	dimensionless	
6	KRTWAT	KRTWAT is a real positive number less than one, that defines the relative permeability of water at the maximum water saturation (normally the maximum water saturation is one) Krwt in the LET relative permeability equations.			1.0
		dimensionless	dimensionless	dimensionless	
7	SORW	SORW is a real positive number less than one that defines the residual oil saturation in and oil-water system in the LET equation.s			0.0
		dimensionless	dimensionless	dimensionless	
8	SOWCR	SOWCR is a real positive number less than one that defines critical oil-in-water saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-water system.			0.0
		dimensionless	dimensionless	dimensionless	
9	LOIL	LOIL is a real positive number that defines the LET Lower empirical parameter Lo for the oil phase with the associated water phase in the LET relative permeability equationss			1.0
		dimensionless	dimensionless	dimensionless	
10	EOIL	EOIL is a real positive number that defines the LET Elevation empirical parameter Eo for the oil phase with the associated water phase in the LET relative permeability equations.			1.0
		dimensionless	dimensionless	dimensionless	
11	TOIL	TOIL is a real positive number that defines the LET Top empirical parameter To for the oil phase with the associated water phase in the LET relative permeability equations.			1.0
		dimensionless	dimensionless	dimensionless	
12	KRTOIL	KRTOIL is a real positive number less than or equal to one, that defines the relative permeability of oil at the residual oil saturation, Krot in the LET relative permeability equations.			1.0
		dimensionless	dimensionless	dimensionless	
13	LPC	LPC is a real positive number that defines the water-oil LET Lower empirical parameter L in the LET capillary pressure equation.			1.0
		dimensionless	dimensionless	dimensionless	
14	EPC	EPC is a real positive number that defines the water-oil LET Elevation empirical parameter E in the LET capillary pressure equation.			1.0
		dimensionless	dimensionless	dimensionless	

No.	Name	Description			Default
		Field	Metric	Laboratory	
15	TPC	TPC is a real positive number that defines the water-oil LET empirical parameter T in the LET capillary pressure equations.			1.0
		dimensionless	dimensionless	dimensionless	
16	PCIR	PCIR is a real positive number that defines the water-oil capillary pressure at connate water saturation (SWL) in the LET capillary pressure equations.			0.0
		psia	bars	atm	
17	PCIT	PCIT is a real positive number that defines the water-oil threshold capillary pressure at the maximum water saturation in the LET capillary pressure equations.			0.0
		psia	bars	atm	

Notes:

1) The keyword is followed by NTSFUN definitions as declared on the TABDIMS keyword in the RUNSPEC section, with each definition consisting of the above 17 LET parameters.
1) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.190: SWOFLET Keyword Description

Note there a two versions of the LET functions, LET[259] for two-phase flowing conditions and LETx[262] for three-phase flowing conditions. This keyword implements the LET version for an oil-water system.

The functions are dependent on the drainage and imbibition cycle of the wetting phase as well as drainage and inhibition cycle number, since a reservoir may undergo several flooding events. To account for this the system defines the flooding event using the three saturations: Sw, So, and Sg together with the state of the three saturations during the flooding event. The saturation state can be Increasing, Decreasing, or Constant, for a given flooding event cycle number (n). Thus, Sw(D), So(I), Sg(C)1or DIC1, means the water phase is decreasing, the oil phase is increasing and the gas phase is constant for the primary or first cycle (n equals one). This is case for when oil is migrating into the reservoir rock and displacing the initial water contained with the reservoir.

Note

All the LET parameters are dependent on the flooding event and flooding cycle, and thus are expected vary as such. To be clear, the values of SWCR, Lo, Lw etc. should be different for each flooding cycle.

See also the *SGOFLET– Gas-Oil LET Relative Permeability Functions*, and the *SGWFLET – Gas-Water LET Relative Permeability Functions* keywords in this section.

[262] *Lomeland F. and Ebeltoft E., 2013. Versatile Three-phase Correlations for Relative Permeability and Capillary Pressure. Paper SCA2013-034 presented at the International Symposium of the Society of Core Analysts held in Napa Valley, California, USA, 16-19 September, 2013.*

Example

The following example uses the SWOFLET keyword to define two relative oi-water relative permeability tables, based on NTSFUN equals two on the TABDIMS keyword in the RUNSPEC section.

```
--
--       SWOFLET – WATER-OIL LET REL. PERMEABILITY FUNCTIONS (OPM FLOW KEYWORD)
--
SWOFLET
--       SWL       SWCR     L-WAT     E-WAT     T-WAT     KRT-WAT
--       SOR       SOWCR    L-OIL     E-OIL     T-OIL     KRT-OIL
--       L-PC      E-PC     T-PC      PCIR      PCIT
--       -------   ------   -------   -------   -------   -------
         0.00000   0.0000   1.00000   1.00000   1.00000   1.00000
         0.00000   0.0000   1.00000   1.00000   1.00000   1.00000
         1*        1*       1*        1*        1*                  / TABLE NO. 01

         0.00000   0.0000   1.00000   1.00000   1.00000   1.00000
         0.00000   0.0000   1.00000   1.00000   1.00000   1.00000
         1*        1*       1*        1*        1*                  / TABLE NO. 02
```

Here the SWOFLET keyword parameters are all set to their default values.

8.3.336 SWU – END-POINT SCALING GRID CELL MAXIMUM WATER SATURATION

Description

SWU defines the maximum water saturation for all the cells in the model via an array when the end-point scaling option has been invoked via the ENDSCALE keyword in the RUNSPEC section. The maximum water saturation is defined as the maximum water saturation in a two-phase water relative permeability table.

The keyword can be used with all grid types.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWU	SWU is an array of real numbers assigning the maximum water saturation values to each cell in the model. The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword. Repeat counts may be used, for example 30*0.70			Taken from cell allocated relative permeability table.
		dimensionless	dimensionless	dimensionless	

Notes:

1) Note this the directional independent version of the maximum water saturation array used with the end-point scaling option. If directional end-point scaling has been activated then the SWUX± , SWUX± and SWU± series of keyword should be used.
2) If the value for a cell has been defaulted then OPM Flow uses the value from the cell's relative permeability table.
3) The keyword is terminated by a "/".

Table 8.191: SWU Keyword Description

End-point scaling allows the entered relative permeability functions to be re-scaled based on the saturation end-points allocated to each cell by the SWL, SWCR, SWU, SGL, SGCR, SGU, SOWCR, and SOGCR saturation grid arrays for the saturation end-points, and the KRG, KROG, KROW and KRW relative permeability grid cell arrays for the relative permeability end-point data. In addition end-point scaling may be directional dependent in which case the directional dependent versions of the aforementioned arrays should be used, that is SWUX, SWUY and SWUZ instead of SWU. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected the non-reversible versions of the aforementioned arrays should be used, that is SWUX, SWUX-, SWUY, SWUY-, SWUZ and SWUZ-, instead of the SWU keyword.

Example

```
--
--       DEFINE GRID BLOCK END-POINT SWU DATA FOR ALL CELLS
--       (FOR NX x NY x NZ = 300)
--
SWU
         300*0.700                                                    /
```

The above example defines a constant connate gas saturation of 0.70 to all 300 cells in the model as defined by the DIMENS keyword in the RUNSPEC section.

8.3.337 TEMPNODE - TEMPERATURE TABLE FOR POLYMER SOLUTION VISCOSITY

Description

This keyword defines the reservoir temperature table used to calculate the polymer solution viscosity when the temperature option has been activated by the TEMP keyword in the RUNSPEC section in the commercial simulator. Naturally, the polymer option must also be activated by the POLYMER keyword in the RUNSPEC section in order to use this keyword.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.338 TEMPTVD – ACTIVATE TEMPERATURE FLUX LIMITED TRANSPORT OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

TEMPTVD activates the Temperature Flux Limited Transport option in the commercial simulator, to reduce numerical dispersion for when either the TEMP or THERMAL keywords in the RUNSPEC section have been declared.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.339 TEMPVD - DEFINE THE INITIAL RESERVOIR TEMPERATURE VERSUS DEPTH TABLE

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the initial reservoir temperature versus depth tables for each equilibration region. Note that the TEMPVD keyword is an alias for RTEMPVD, and that both keywords are supported by OPM Flow, in both the PROPS and SOLUTION sections, but are treated as being mutually exclusive.

See *TEMPVD - Define the Initial Reservoir Temperature versus Depth Tables* in the SOLUTION section, as the keyword is documented in the SOLUTION section in this instance, but it can also be used in the PROPS section by OPM Flow.

8.3.340 TLMIXPAR – DEFINE THE MISCIBLE TODD-LONGSTAFF MIXING PARAMETERS

Description

The TLMIXPAR keyword defines the Todd-Longstaff[263] mixing parameters, for when either the miscible or solvent options have been activated by the MISCIBLE or SOLVENT keywords in the RUNSPEC section. This keyword must be present in the input deck if the MISCIBLE or SOLVENT keywords have been activated.

Note that If the POLYMER option has been activated by the POLYMER keyword in the RUNSPEC section, then this keyword is ignored and the mixing parameters are taken from the PLMIXPAR keyword instead.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TLMVIS	A real positive value that is greater than or equal to zero and less than or equal to one, that defines the viscosity Todd-Longstaff mixing parameter for each miscibility region.			
		dimensionless	dimensionless	dimensionless	None
2	TLMDEN	A real positive value that is greater than or equal to zero and less than or equal to one, that defines the density Todd-Longstaff mixing parameter for each miscibility region.			The same value as entered for TLMVIS
		dimensionless	dimensionless	dimensionless	

Notes:

1) The keyword is followed by NTMISC tables as declared on the MISCIBLE keyword in the RUNSPEC section, for each rock region. There should be only one row per table.

2) Each entry is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.192: TLMIXPAR Keyword Description

Example

```
--
--       TODD-LONGSTAFF MIXING PARAMETERS
--
TLMIXPAR
--       TLM         TLM
--       VISCOS      DENSITY
--       -------     --------
         0.3500       0.3500                          / TABLE NO. 01
         0.2500       1*                              / TABLE NO. 02
         0.6500       0.7500                          / TABLE NO. 03
```

The above example defines three Todd-Longstaff mixing parameter data sets, based on the NTMISC variable on the MISCIBLE keyword in the RUNSPEC section being equal to three.

[263] *Todd, M. and Longstaff, W. "The Development, Testing and Application of a Numerical Simulator for Predicting Miscible Flood Performance," paper SPE 3484, Journal of Canadian Petroleum Technology (1972) 24, No. 7, 874-882.*

8.3.341 TOLCRIT – DEFINE THE CRITICAL SATURATION TOLERANCE

Description

Critical fluid saturations are determined from the relative permeability tables, that is the last saturation in a relative permeability table where the relative permeability of a phase is set equal to zero. Since floating-point numbers (as implemented in computers) are never exact, one cannot compare floating point numbers for exact equality. Thus, this keyword defines a value below which is considered equivalent to zero in determining the critical saturation for a phase.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TOLCRIT	TOLCRIT is a real positive number greater than zero and less than one that defines the critical saturation tolerance used to determine the critical saturation of a fluid in the relative permeability tables. The default value of 1 x 10-6 means that saturation values less than this value will be treated as being equal to zero.			
		dimensionless	dimensionless	dimensionless	1 x 10^{-6}
Notes: 1) The keyword is terminated by a "/".					

Table 8.193: TOLCRIT Keyword Description

See also section *8.2.4 Saturation Tables (Relative Permeability and Capillary Pressure Tables)* for a description of the relative permeability tables and the various end-point definitions, including oil, water and gas critical saturations.

Example

```
---
--       SET THE CRITICAL SATURATION TOLERANCE
--
TOLCRIT
         1.0E-6                                                    /
```

The above example defines the critical saturation tolerance to be the default value of 1 x 10-6.

8.3.342 TPAMEPS – VOLUMETRIC STRAIN VERSUS COAL GAS CONCENTRATION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

TPAMEPS defines the volumetric strain versus coal gas concentration tables, for when the Coal Bed Methane option has been activated via the COAL keyword, and PALM-MAN has been declared for the ROCKOPT variable on the ROCKCOMP keyword; both keywords are in the RUNSPEC section. The Palmer-Mansoorii[264] and [265] rock model is used to calculate the impact on pore volume and permeability due to rock compaction.

See also the ROCKPARMA keyword in the PROPS section that defines the Palmer-Mansoori parameters.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[264] *Palmer, I. and Mansoori, J. "How Permeability Depends on Stress and Pore Pressure in Coalbeds: A New Model," paper SPE 52607, SPE Reservoir Evaluation & Engineering (1998) 1, No. 6, 539-544.*

[265] *Clarkson, C.R., Pan, Z., Palmer, I. and Harpalani, S. "Predicting Sorption-Induced Strain and Permeability Increase With Depletion for Coalbed-Methane Reservoirs", SPE 114778-PA, SPE Journal (2010) 15, No. 1, 152–159.*

8.3.343 TPAMEPSS - VOLUMETRIC STRAIN VERSUS COAL SOLVENT CONCENTRATION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

TPAMEPSS defines the volumetric strain versus coal solvent concentration tables, for when the Coal Bed Methane option has been activated via the COAL keyword, and PALM-MAN has been declared for the ROCKOPT variable on the ROCKCOMP keyword; both keywords are in the RUNSPEC section. The Palmer-Mansoorii[266] and [267] rock model is used to calculate the impact on pore volume and permeability due to rock compaction.

See also the ROCKPARMA keyword in the PROPS section that defines the Palmer-Mansoori parameters.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

[266] *Palmer, I. and Mansoori, J. "How Permeability Depends on Stress and Pore Pressure in Coalbeds: A New Model," paper SPE 52607, SPE Reservoir Evaluation & Engineering (1998) 1, No. 6, 539-544.*

[267] *Clarkson, C.R., Pan, Z., Palmer, I. and Harpalani, S. "Predicting Sorption-Induced Strain and Permeability Increase With Depletion for Coalbed-Methane Reservoirs", SPE 114778-PA, SPE Journal (2010) 15, No. 1, 152–159.*

8.3.344 TRACER – DEFINE PASSIVE TRACER VARIABLES

Description

The TRACER keyword defines a series of passive tracers that are associated with a phase (oil, water, or gas) in the model. The maximum number of tracers for each phase are declared on the TRACERS keyword in the RUNSPEC section.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	NAME	A three letter character string defining the tracer's name. NAME is used by the TNUM keyword in the REGIONS section, and unlike other keywords, the TNUM keyword itself must be concatenated with the phase and the name of the tracer defined by NAME. Similarly for the TVDP keyword in the SOLUTION section, where the TVDP keyword itself must be concatenated with the either letter F (for free) or S (for solution), followed by the name of the tracer defined by NAME. Note it is best to void names beginning with the letters F, S, and T as these names may create naming issues in post-processing software.			None
2	PHASE	A three letter character string that defines the tracer given by NAME to a particular fluid phase. The character should be set to OIL, WAT or GAS.			None
3	UNITS	The units for the tracer. This can be any unit but should be consistent with values entered via the TBLK and TVDP keywords in the SOLUTION section. The default values are the same as the PHASE in the model.			Same as the phases in the model
		Liquid: stb Gas: Mscf	Liquid: sm^3 Gas: sm^3	Liquid: scc Gas: scc	
4	SOLPHASE	A three or four letter character string defining the partitioned tracer's solution phase. The character string should be set to OIL, WAT, GAS or MULT. Note that SOLPHASE only needs to be defined if the partitioned tracer option has been activate with the PARTTRAC keyword in the RUNSPEC section.			None
5	KPNUM	The table number to be used with the partitioned tracers defined by the PARTTRAC, TRACERKP and TRACERKM keywords. Note that KPNUM only needs to be defined if the partitioned tracer option has been activate with the PARTTRAC keyword in the RUNSPEC section.			None
6	ADSPHASE	A three letter character string defining the phase used for the adsorption calculation for when the MULT option has been for SOLPHASE. The character string should be set to OIL, WAT, GAS or ALL. Note that ADSPHASE only needs to be defined if the partitioned tracer option has been activate with the PARTTRAC keyword in the RUNSPEC section.			None

No.	Name	Description			Default
		Field	Metric	Laboratory	
Notes: 1) Each record (or row) should be terminated by a "/" and the keyword is terminated by a "/".					

Table 8.194: TRACER Keyword Description

See also the TNUM keyword in the REGION section that defines tracer regions, and the TVDP keyword in the SOLUTION section that sets the initial tracer saturation for all the cells as a function of depth.

Example

```
--
--       DEFINE TRACER NAMES
--
--       TRACER   TRACER
--       NAME     PHASE
--       ------   ------
TRACER
        'IGS'     'GAS'                                  / GAS INJECTOR
        'DGS'     'GAS'                                  / DISOLVED GAS
        'IW1'     'WAT'                                  / WAT INJECTOR 1
        'Iw2'     'WAT'                                  / WAT INJECTOR 2
/
```

The above example defines four passive tracers one for a gas injection well, one for tracking the dissolved gas, and two to track the injected water from two water injection wells.

8.3.345 TRACERKM – MULTI-PARTITIONED TRACER OPTION K(P) TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, TRACERKM, defines the Multi-Partitioned Tracer option K(P) tables, for when the Partitioned Tracer option has been activate with the PARTTRAC keyword in the RUNSPEC section, and the SOLPHASE parameter on the TRACER keyword in the PROPS section has been set to MULT to activate the Multi-Partitioned Tracer option. Multi-partitioned tracers can partition into any number of phases (oil, water, gas etc.) and have adsorption, decay and diffusion parameters specific to each phase; whereas the standard partitioned tracers only have a "free" and "solution" phases. For the TRACERKM keyword the K(P) tables relate the ratio of the reference phase to the other phases versus pressure. So for example, given a multi-partitioned tracer in oil, water and gas, with the water phase acting as the reference phase, then TRACERKM would consist of columnar vectors of:

$$K_{ow}(P) = \frac{C_{oil}}{C_{water}} \quad \text{and} \quad K_{gw}(P) = \frac{C_{gas}}{C_{water}} \tag{8.96}$$

Where:

$Kow(P)$	= multi-partitioned oil-water K(P)
$Kgw(P)$	= multi-partitioned gas-water K(P)
$Coil$	= oil concentration
$Cgas$	= gas concentration
$Cwater$	= water concentration

See also the TRACERKP keyword in the PROPS section that provides similar data for standard partitioned tracers.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.346 TRACERKP – STANDARD PARTITIONED TRACER OPTION K(P) TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, TRACERKP, defines the Standard Partitioned Tracer option K(P) tables, for when the Partitioned Tracer option has been activate with the PARTTRAC keyword in the RUNSPEC section. Standard partitioned tracers only have a "free" and "solution" phases; whereas, Multi-partitioned tracers can partition into any number of phases (oil, water, gas etc.) and have adsorption, decay and diffusion parameters specific to each phase. For the TRACERKP keyword the K(P) tables relate the ratio of the reference phase (the "free" phase) to the solution phase versus pressure. So for example, given a standard partitioned tracer in oil and gas, with the oil phase acting as the reference phase, then TRACERKP would consist of columnar vectors of:

$$K(P) = \frac{C_{gas}}{C_{oil}} \tag{8.97}$$

Where:

$K(P)$ = standard partitioned K(P)
$Coil$ = oil concentration
$Cgas$ = gas concentration

See also the TRACERKM keyword in the PROPS section that provides similar data for tmulti-partitioned tracers.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.347 TRACITVD – ACTIVATE AND DEFINE TRACER IMPLICIT FLUX LIMITED TRANSPORT OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

TRACITVD activates the Tracer Implicit Flux Limited Transport option and sets various parameters for this option. Basically the option is used to control numerical dispersion for tracers. Both the TRACERS keyword in the RUNSPEC section and the TRACER keyword in the PROPS section must be declared to activate tracers and to define the tracers.

See also the TRACTVD keyword in the PROPS section activates the Tracer Explicit Flux Limited Transport option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.348 TRACTVD – ACTIVATE TRACER EXPLICIT FLUX LIMITED TRANSPORT OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

TRACTVD activates the Tracer Explicit Flux Limited Transport option. Basically the option is used to control numerical dispersion for tracers. Both the TRACERS keyword in the RUNSPEC section and the TRACER keyword in the PROPS section must be declared to activate tracers and to define the tracers.

See also the TRACITVD keyword in the PROPS section activates the Tracer Implicit Flux Limited Transport option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.349 TRADS – ENVIRONMENTAL TRACER ADSORPTION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, TRADS, specifies the environmental tracer adsorption tables that describe how a tracer is absorbed by the surrounding rock, for when the MXENVTR parameter has been set to greater than zero on the TRACERS keyword in the RUNSPEC section to activate environmental tracers. The keyword can only be used with environmental tracers.

Unlike other keywords, the TRADS keyword must be concatenated with the three character name of the tracer declared by TRACER keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.350 TRDCY – ENVIRONMENTAL TRACER DECAY TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, TRDCY, specifies the environmental tracer decay tables that specifies the tracer decay half-life, for when the MXENVTR parameter has been set to greater than zero on the TRACERS keyword in the RUNSPEC section to activate environmental tracers. The keyword can only be used with environmental tracers.

Unlike other keywords, the TRSCY keyword must be concatenated with the three character name of the tracer declared by TRACER keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.351 TRDIF – TRACER DIFFUSION TABLES

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, TRDIF, specifies the tracer diffusion tables that specify the diffusion coefficient for a tracer. The keyword can be used with Environmental Tracers if the MXENVTR parameter has been set greater than zero on the TRACERS keyword in the RUNSPEC section. When used with a Standard Partitioned Tracer the diffusion coefficient applies to the solution phase, whereas as for a Multi-Partitioned Tracer the diffusion coefficient can be entered for each defined tracer phase. Unlike other keywords, the TRADS keyword must be concatenated with the three character name of the tracer declared by TRACER keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.352 TRDIS – TRACER DISPERSION TABLE NUMBER ALLOCATION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, TRDIS, specifies the tracer diffusion tables that should be allocated to a tracer, the actual dispersion tables are specified by the DISPERSE keyword in the PROPS section. The keyword can be used with Environmental Tracers if the MXENVTR parameter has been set greater than zero on the TRACERS keyword in the RUNSPEC section. The option does not work with two-phase Standard Partitioned Tracers and Multi-Partitioned Tracers. Unlike other keywords, the TRADS keyword must be concatenated with the three character name of the tracer declared by TRACER keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.353 TRNHD – ACTIVATE DISPERSION NON-HOMOGENEOUS DIFFUSION OPTION

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The TRNHD keyword activates the Dispersion Non-Homogeneous Diffusion option for when tracer dispersion is independent of velocity or tracer concentration. Unlike other keywords, the TRNHD keyword must be concatenated with the name of the tracer declared by TRACER keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.354 TRROCK – ENVIRONMENTAL TRACER-ROCK PROPERTY DATA

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword, TRROCK, specifies the environmental tracer rock data for the tracer adsorption model, for when the MXENVTR parameter has been set to greater than zero on the TRACERS keyword in the RUNSPEC section to activate environmental tracers. The keyword can only be used with environmental tracers.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.355 TZONE – END-POINT SCALING TRANSITION ZONE OPTIONS

Description

The TZONE keyword sets the transition end-point scaling options for the oil, water and gas phases, for when the End-Point Scaling option has been activated by the ENDSCALE keyword in the RUNSPEC section. The keyword determines if the phase critical saturation should or should not be set to the initial immobile saturation in areas where the initial saturation is below the entered critical saturation.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	OILZONE	OILZONE is a single character that sets the oil phase transition zone end-point scaling option and should be set to either T or F: 1) T: for true, results in the SOWCR values being adjusted to the initial immobile saturation for oil-water or oil-water-miscible gas simulations. For oil-gas simulations the SOGCR values are modified to be the initial immobile saturation. The modifications only occur in cells where the initial saturation is below the entered critical saturation. 2) F: for false, means the critical saturations are not modified.	F
2	WATZONE	WATZONE is a single character that sets the water phase transition zone end-point scaling option and should be set to either T or F: 1) T: for true, results in the SWCR values being adjusted to the initial immobile saturations. The modifications only occur in cells where the initial saturation is below the entered critical saturation values (SWCR). 2) F: for false, means the critical saturations are not modified.	F
3	GASZONE	GASZONE is a single character that sets the gas phase transition zone end-point scaling option and should be set to either T or F: 1) T: for true, results in the SGCR values being adjusted to the initial immobile saturation for oil-gas or gas-water simulations. The modifications only occur in cells where the initial saturation is below the entered critical saturation (SGCR). 2) F: for false, means the critical saturations are not modified.	F
Notes: 1) The keyword is terminated by a "/".			

Table 8.195: TZONE Keyword Description

See also the SCALECRS keyword in the PROPS section that sets the end-point scaling option to be either two-point or three-point scaling.

Example

```
--
--       END-POINT SCALING TRANSITION ZONE OPTIONS
--
--       OILZONE  WATZONE  GASZONE
--       -------  -------  -------
TZONE
         F        T        F                                / SCALING OPTION
```

The above example results in the SWCR values being adjusted to the initial immobile saturations.

8.3.356 VDFLOW – VELOCITY DEPENDENT FLOW COEFFICIENT FOR GRID BLOCK FLOW (GRID)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

VDFLOW activates non-Darcy flow between grid blocks and defines a constant non-Darcy flow coefficient for the whole grid, the coefficient only applies to the gas phase. The coefficient is normally derived from well tests or calculated analytically based on the coefficient of inertial resistance, usually known as β, in Forchheimer's flow equation,[268], [269] and [270]. Dake[271], in chapter eight, reports a typical value of β to be 10.07 cm-1.

See also the VDFLOWR keyword in the PROPS section that allows the non-Darcy coefficient to be entered for individual regions, and the WDFAC and WDFACCOR keywords in the SCHEDULE section that assigns the non-Darcy coefficient to well connections.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.357 VDFLOWR – VELOCITY DEPENDENT FLOW COEFFICIENT FOR GRID BLOCK FLOW (REGION)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

VDFLOW activates non-Darcy flow between grid blocks and defines a constant non-Darcy flow coefficient for individual regions allocated by the SATNUM keyword in the REGIONS section. Note that the coefficient only applies to the gas phase. The coefficient is normally derived from well tests or calculated analytically based on the coefficient of inertial resistance, usually known as β, in Forchheimer's flow equation,[272], [273] and [274]. Dake[275], in chapter eight, reports a typical value of β to be 10.07 cm-1.

See also the VDFLOW keyword in the PROPS section that allows the non-Darcy coefficient to be entered for the whole grid, and the WDFAC and WDFACCOR keywords in the SCHEDULE section that assigns the non-Darcy coefficient to well connections.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.358 VEFRAC – VERTICAL EQUILIBRIUM RELATIVE PERMEABILITY FRACTION (GRID)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the Vertical Equilibrium ("VE") relative permeability weighting factor (α) used to calculate the VE relative permeability curves to be used in the simulation, for when the VE option has been activated by the VE keyword in the RUNSPEC section. If α = 1.0, then the VE model calculated relative permeability curves will be used, and if α = 0.0, then the curves entered via the SWOF, SGOF, SLGOF series of keywords or the SWFN, SGFN, SGWFN, SOF2, SOF3, SOF32D series of keywords, will be used. A value of α between zero and one will result in weighted average relative permeability curves being employed, that is:

$$VE_{(average)} = (1.0 - \alpha) \times (SATNUM_{curves}) + \alpha \times (VE\ Model_{curves}) \quad (8.98)$$

Note that VEFRAC sets α for the whole grid; whereas, the VEFRACV keyword in the PROPS section assigns α on a cell by cell basis, See also the VEFRACP and VEFRACPV keywords that apply the weighting factors to the capillary pressure data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.359 VEFRACP – VERTICAL EQUILIBRIUM CAPILLARY PRESSURE FRACTION (GRID)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the Vertical Equilibrium ("VE") capillary pressure weighting factor (α) used to calculate the VE capillary pressure curves to be used in the simulation, for when the VE option has been activated by the VE keyword in the RUNSPEC section. If α = 1.0, then the VE model calculated capillary pressure curves will be used, and if α = 0.0, then the curves entered via the SWOF, SGOF, SLGOF series of keywords or the SWFN, SGFN, SGWFN, SOF2, SOF3, SOF32D series of keywords, will be used. A value of α between zero and one will result in weighted average capillary pressure curves being employed, that is:

$$VE_{(average)} = (1.0 - \alpha) \times (SATNUM_{curves}) + \alpha \times (VE\ Model_{curves}) \quad (8.99)$$

Note that VEFRACP sets α for the whole grid; whereas, the VEFRACPV keyword in the PROPS section assigns α on a cell by cell basis, See also the VEFRAC and VEFRACV keywords that apply the weighting factors to the relative permeability data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.360 VEFRACPV – VERTICAL EQUILIBRIUM CAPILLARY PRESSURE FRACTION (CELL)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the Vertical Equilibrium ("VE") capillary pressure weighting factor (α) used to calculate the VE capillary pressure curves to be used in the simulation, for when the VE option has been activated by the VE keyword in the RUNSPEC section. If α = 1.0, then the VE model calculated capillary pressure curves will be used, and if α = 0.0, then the curves entered via the SWOF, SGOF, SLGOF series of keywords or the SWFN, SGFN, SGWFN, SOF2, SOF3, SOF32D series of keywords, will be used. A value of α between zero and one will result in weighted average capillary pressure curves being employed, that is:

$$VE_{(average)} = (1.0 - \alpha) \times (SATNUM_{curves}) + \alpha \times (VE\ Model_{curves}) \quad (8.100)$$

Note that VEFRACPV sets α on a cell by cell basis; whereas, the VEFRACP keyword in the PROPS section assigns α for the whole grid, See also the VEFRAC and VEFRACV keywords that apply the weighting factors to the relative permeability data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.361 VEFRACV – VERTICAL EQUILIBRIUM RELATIVE PERMEABILITY FRACTION (CELL)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

This keyword defines the Vertical Equilibrium ("VE") relative permeability weighting factor (α) used to calculate the VE relative permeability curves to be used in the simulation, for when the VE option has been activated by the VE keyword in the RUNSPEC section. If α = 1.0, then the VE model calculated relative permeability curves will be used, and if α = 0.0, then the curves entered via the SWOF, SGOF, SLGOF series of keywords or the SWFN, SGFN, SGWFN, SOF2, SOF3, SOF32D series of keywords, will be used. A value of α between zero and one will result in weighted average relative permeability curves being employed, that is:

$$VE_{(average)} = (1.0 - \alpha) \times (SATNUM_{curves}) + \alpha \times (VE\ Model_{curves}) \quad (8.101)$$

Note that VEFRACVV sets α on a cell by cell basis; whereas, the VEFRAC keyword in the PROPS section assigns α for the whole grid, See also the VEFRACP and VEFRACPV keywords that apply the weighting factors to the capillary pressure data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

8.3.362 VISCREF - DEFINE VISCOSITY-TEMPERATURE REFERENCE CONDITIONS

Description

VISCREF defines the reference conditions for the viscosity-temperature tables, GASVISCT, OILVISCT and WATVISCT, for when the thermal option has been activated by THERMAL keyword in the RUNSPEC section. This keyword can only be used if the thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRES	PRES is a real positive number defining the reference pressure for the viscosity and temperature tables			
		psia	barsa	atma	None
2	RS	RS is a real positive number defining the reference gas-oil ratio for when the model contains gas dissolved as activated by the DISGAS keyword in the RUNSPEC section			
		Mscf/stb	sm^3/sm^3	scc/scc	None
3	API	API is a real number defining the oil API for when the API tracking option has been invoked by the API keyword in the RUNSPEC section. Note that OPM Flow does not support API tracking, and therefore this variable is ignored.			
		°API	°API	°API	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.196: VISCREF Keyword Description

OPM Flow currently does not support API tracking and therefore item (3) of this keyword is ignored. See also the OILVISCT, GASVISCT and WATVISCT keywords in the PROPS section.

Example

The following example shows the VISCREF keyword for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to five.

```
--
--       REF         REF        REF
--       PRESSURE    GOR        API
--       --------    -------    -------
VISCREF
          3000.0     0.500                                  / TABLE NO. 01
          3200.0     0.550                                  / TABLE NO. 02
          3300.0     0.580                                  / TABLE NO. 03
          3400.0     0.620                                  / TABLE NO. 04
          3500.0     0.625                                  / TABLE NO. 05
```

There is no terminating "/" for this keyword.

8.3.363 WAGHYSTR – DEFINE WATER-ALTERNATING-GAS HYSTERESIS PARAMETERS

Description

This keyword defines the parameters for the Water-Alternating-Gas ("WAG") hysteresis option, for when the hysteresis option has been activated by the WAGHYSTR variable on the SATOPTS keyword in the RUNSPEC section.

The WAG recovery mechanism is an Enhanced Oil Recovery ("EOR") process to optimize oil recovery by improving volumetric sweep efficiency. It was originally proposed as a method to improve the sweep efficiency of gas by using water to control the mobility ratio and to stabilize the front (Caudle and Dyes, 1958[276]; Christensen et al., 1998[277]; and Christensen et al., 2001[278]). WAG injection can lead to improved oil recovery by combining better mobility control and contacting upswept zones, and by leading to improved microscopic displacement. Although initially the injected gas was immiscible with respect to the oil (WAG Immiscible) the more common process is WAG Miscible, with alternating different types of hydrocarbon gases and non-hydrocarbon gases, such as N2 and CO2 Gases. WAG flooding has been successfully applied to various fields worldwide.

Only the gas phase relative permeability WAG hysteresis model has been implemented in the simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	LANDS_PARAMETER	A real value greater than zero that defines Land's parameter, C. The Land's parameter controls how the trapped gas saturation depends on the maximum gas saturation attained and the critical gas saturation; and the shape of the imbibition curve. $$s_{gtrap} = s_{gcr} + \frac{(s_{gm} - s_{gcr})}{(1 + C(s_{gm} - s_{gcr}))}$$ where, s_{gtrap} is the trapped gas saturation, s_{gm} is the maximum gas saturation attained, and s_{gcr} is the critical gas saturation. Values of the Land's parameter that are too small give a trapped gas saturation close to the maximum gas saturation attained. This results in an unphysical steep relative permeability curve giving potential convergence problems.			None
		dimensionless	dimensionless	dimensionless	
2	SECONDARY_DRAINAGE_REDUCTION	A real value greater than or equal to zero that defines the secondary drainage reduction factor, alpha. As alpha increases the reduction in gas mobility on secondary drainage increases.			0.0

[276] *Caudle, B. H., & Dyes, A. B. (1958, January 1). Improving Miscible Displacement by Gas-Water Injection. Society of Petroleum Engineers.*

[277] *Christensen, J. R., Stenby, E. H., & Skauge, A. (1998, January 1). Review of WAG Field Experience. Society of Petroleum Engineers. doi:10.2118/39883-MS.*

[278] *Christensen, J. R., Stenby, E. H., & Skauge, A. (2001, April 1). Review of WAG Field Experience. Society of Petroleum Engineers. doi:10.2118/71203-PA.*

No.	Name	Description			Default
		Field	Metric	Laboratory	
		dimensionless	dimensionless	dimensionless	
3	GAS_MODEL	A defined character string that defines whether the gas hysteresis model should be used, and should be set to one of the following character strings: 1) YES: Use the WAG hysteresis model for the gas phase relative permeability. 2) NO: Turn off the WAG hysteresis model and use the drainage curve. Only the YES option is currently supported by the simulator.			YES
4	RES_OIL	A defined character string that defines whether the residual oil model should be used, and should be set to one of the following character strings: 1) YES: Use the trapped gas to modify the residual oil saturation (SOM) in the STONE I three-phase oil relative permeability model. No action is taken unless the STONE1 keyword has been entered. 2) NO: Do not modify the residual oil saturation. Only the NO option is currently supported by the simulator.			YES
5	WATER_MODEL	A defined character string that defines whether the water hysteresis model should be used, and should be set to one of the following character strings: 1) YES: Use the WAG hysteresis model for the water phase relative permeability 2) NO: Turn off the WAG hysteresis model. Note that the hysteresis model specified in EHYSTR keyword applies. Only the NO option is currently supported by the simulator.			YES
6	IMB_LINEAR_FRACTION	A real value greater than zero that defines the imbibtion curve linear fraction. This is the fraction of the curve between Sgm and Sgtrap that uses a linear transformation. A non-zero value for the linear fraction prevents the potential infinite gradient in the imbibition curve when using the Carlson analytic model.			0.1
		dimensionless	dimensionless	dimensionless	
7	THREEPHASE_SAT_LIMIT	A real value between zero and one that defines the three-phase model threshold saturation. When the water saturation exceeds this threshold above the connate water saturation the gas (non-wetting) phase hysteresis switches from the two-phase model to the three-phase model. In the two-phase model a secondary drainage process follows the imbibition curve. However, if the water saturation exceeds the connate saturation by the given threshold, at the beginning of the secondary drainage process a three-phase secondary drainage curve is followed. This value also defines the minimum percentage change in gas saturation to allow switching from drainage to imbibition curve and vice-versa. This threshold allows better control of the numerical sensitivity of the system, preventing it from being too unstable.			0.001
		dimensionless	dimensionless	dimensionless	

No.	Name	Description			Default
		Field	Metric	Laboratory	
8	RES_OIL_MOD_FRACTION	A real value between zero and one that defines the residual oil modification fraction. This is the fraction of the trapped gas saturation subtracted from the residual oil (SOM) in the STONE I three-phase oil relative permeability model. This is not supported and will be ignored by the simulator.			1.0
		dimensionless	dimensionless	dimensionless	

Notes:

1) The keyword is followed by one record for each saturation table region with each record terminated by a "/".
2) The number of saturation table regions NTSFUN is specified by the TABDIMS keyword in the RUNSPEC section.

Table 8.197: WAGHYSTR Keyword Description

Example

The following example defines the WAG hysteresis model parameters using the WAGHYSTR keyword for a case with three saturation table regions

```
--
--        WAG HYSTERESIS PARAMETERS
--
-- LAND   ALPHA     GAS     RES     WATER   LINEAR
-- C      FACTOR    MODEL   OIL     MODEL   FRAC
WAGHYSTR
2.0       1.0       YES     YES     YES     0.2     /
2.0       1.0       YES     NO      /
2.0       /
```

Here, saturation table region one uses the gas WAG hysteresis, residual oil and water WAG hysteresis models, with a Land's parameter of 2.0, an alpha factor of 1.0, and a imbibition curve linear factor of 0.2. The gas and water WAG hysteresis models are used in region two but the residual oil model is turned off, with a Land's parameter of 2.0, an alpha factor of 1.0, and a default imbibition curve linear factor of 0.1. A Land's parameter of 2.0 has been specified for region three with the remainder of the parameters defaulted.

Note that the above example uses some options that are not currently supported by OPM Flow.

8.3.364 WARN – ACTIVATE WARNING MESSAGES

Turns on warning messages to be printed to the print file (*.PRT); note that this keyword is activated by default and can subsequently be switched off by the NOWARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN. OPM Flow always prints error messages.

See *WARN – Activate Warning Messages* in the GLOBAL section for a full description.

8.3.365 WATDENT – DEFINE WATER DENSITY TEMPERATURE COEFFICIENTS

Description

WATDENT defines the water density as a function of temperature coefficients for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC. Note this is an OPM Flow keyword used with OPM Flow's black-oil thermal model that is not available in the commercial simulator's black-oil thermal formulation.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	TEMP is a real positive value greater than zero that defines the absolute reference temperature used with TEXP1 and TEXP2 to estimate the change in water density with respect to temperature.			
		°R 527.67	K 293.15	K 293.15	Defined
2	TEXP1	TEXP1 is a real positive value greater than zero that defines the water thermal expansion coefficient of the first order.			
		1/°R 1.67×10^{-4}	1/K 3.0×10^{-4}	1/K 3.0×10^{-4}	Defined
3	TEXP2	TEXP2 is a real positive value greater than zero that defines the water thermal expansion coefficient of the second order.			
		1/°R2 9.26×10^{-7}	1/K2 3.0×10^{-6}	1/K2 3.0×10^{-6}	Defined

Notes:

1) The keyword is followed by NTPVT records as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each data set is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.198: WATDENT Keyword Description

The water density at a given pressure and temperature is calculated from its value at surface conditions and the water shrinkage factor (the reciprocal of the water formation volume factor) as shown in the following equation:

$$\rho_w(p,T) = \rho_w(p_s,T_s)\, b_w(p,T) \tag{8.102}$$

Where the temperature dependence of the water shrinkage factor relative to its value at the reference temperature is calculated as shown in the following equation:

$$b_w(p,T)=\frac{b_w(p,T_{ref})}{1+c_1(T-T_{ref})+c_2(T-T_{ref})^2} \quad (8.103)$$

Where:

ρ_w = water density
b_w = water shrinkage factor
p = pressure
T = temperature
c_1, c_2 = thermal expansion coefficients to first and second order
s = subscript indicating surface conditions
ref = subscript indicating reference conditions

Example

The following example shows the WATDENT keyword using the default values, for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set to two.

```

         1*         1*        1*                          / TABLE NO. 01
         1*         1*        1*                          / TABLE NO. 02
```

There is no terminating "/" for this keyword.

8.3.366 WATJT – DEFINE WATER JOULE-THOMSON COEFFICIENT

Description

WATJT activates the water Joule-Thomson effect[279] in temperature calculations, and defines the water Joule-Thomson Coefficient ("JTC") at a given reference pressure, for when OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC.

Note

This is an OPM Flow keyword used with OPM Flow's black-oil thermal model, that is not available in the commercial simulator's black-oil thermal formulation.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model, and does not include the Joule-Thomson effect in temperature calculations.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	PRESS	A real positive value that defines the reference pressure for the corresponding Joule-Thomson Coefficient, WATJTC.			
		psia	barsa	atma	None
2	WATJTC	WATJTC is a real positive or negative value that defines the water phase Joule-Thomson Coefficient. If the value is defaulted (1*) or set to 0, then WATJTC is internally calculated using thermal water density data on the WATSDENT keyword in the PROPS section. If a non-zero value is specified, then the WATJTC is assumed to be constant and equal to that value.			
		oF/psia	°C/barsa	°C/atma	0

Notes:

1) The keyword is followed by NTPVT records as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each data set is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.199: WATJT Keyword Description

The Joule–Thomson effect is when a real gas, as oppose to an ideal gas, expands, resulting in the temperature of the gas dropping[280]. For liquids the effect is the opposite, that is the internal energy is transferred to kinetic energy with a corresponding increase in temperature as velocity increases.

Thermodynamically, the Joule–Thomson coefficient is defined as the isenthalpic[281] change in temperature in a fluid caused by a unitary pressure drop, as shown in the following equation:

[279] *The Joule–Thomson coefficient is defined as the change in temperature with respect to an increase in pressure at constant enthalpy.*

[280] *Natural Gas Engineering (McGraw-Hill chemical engineering series), Donald L. Katz, Robert I Lee, McGraw-Hill Education, 1990 (ISBN 0071007776, 9780071007771).*

$$\eta = \left(\frac{\partial T}{\partial P}\right) \tag{8.104}$$

Which can also express as[282]:

$$\eta = (T\alpha - 1)\frac{1}{(\rho C_p)} - \left(\frac{g}{C_p}\frac{dp}{dz}\right)^{-1} \tag{8.105}$$

Setting the gravity term, g, to zero we have:

$$\eta = (T\alpha - 1)\frac{1}{(\rho C_b)} \tag{8.106}$$

Where:

η	=	Joule–Thomson coefficient (oC/Pa),
α	=	thermal expansivity at constant pressure (1/oC),
C_p	=	specific heat at constant pressure (J/kg oC),
g	=	gravitational acceleration (m/s2)
P	=	pressure (Pa),
T	=	temperature (oC), and
z	=	height (m).

Example

The following example shows the WATJT keyword for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section, and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set equal to two.

```
--
--       WATER JOULE-THOMSON COEFFICIENT (OPM FLOW EXTENSION KEYWORD)
--
--       REF         OIL
--       PRESS       JTC
--       --------    -------
WATJT
         20.0        1*                  / TABLE NO. 01
         20.0        -0.20               / TABLE NO. 02
```

Here the first entry is defaulted, and the simulator will therefore calculate the water JTC internally using the data on the WATDENT keyword in the PROPS section.

There is no terminating "/" for this keyword.

[281] *An isenthalpic process or isoenthalpic process, is a process that proceeds without any change in enthalpy, H; or specific enthalpy, h.*

[282] *Pippard, A.B.: Elements of Classical Thermodynamics: For Advanced Students of Physics. Cambridge University Press, Cambridge, UK (1957)*

8.3.367 WATVISCT – DEFINE WATER VISCOSITY VERSUS TEMPERATURE FUNCTIONS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

WATVISCT defines the water viscosity as a function of temperature for when thermal option has been activated by the THERMAL keywords in the RUNSPEC. The reference pressure for this table is given by the VISCREF keyword in the PROPS section.

This keyword can only be used if OPM Flow's thermal option has been activated by the THERMAL keyword in the RUNSPEC section. Note this is different to the commercial simulator that uses the TEMP keyword in the RUNSPEC section to activate the black-oil thermal model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	TEMP	A columnar vector of real monotonically increasing down the column values that defines the temperature values.			
		°F	°C	°C	None
2	VIS	A columnar vector of real decreasing down the column values that defines the water viscosity for the corresponding temperature values (TEMP). VIS should be given at the reference pressure defined by the PRESS variable on the VISCREF keyword.			
		cP	cP	cP	None

Notes:

1) The keyword is followed by NTPVT tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NPPVT rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.200: WATVISCT Keyword Description

Example

The following example shows the WATVISCT keyword for when the thermal option has been activated by the THERMAL keyword in the RUNSPEC section and for when NTPVT on the TABDIMS keyword in the RUNSPEC section is set equal to one.

```
--
--       WATER VISCOSITY VERSUS TEMPERATURE TABLES
--
--       WATER      WATER
--       TEMP       VISC
--       --------   -------
WATVISCT
           100.0    0.625
           110.0    0.620
           120.0    0.580
           150.0    0.550
           165.0    0.500                                  / TABLE NO. 01
```

There is no terminating "/" for this keyword.

8.3.368 WSF - WATER SATURATION TABLES VERSUS WATER SATURATION (GAS-WATER AND CO2STORE SYSTEMS)

Description

The WSF keyword defines the water relative permeability data versus water saturation tables for when gas and water are only present in the input deck. This keyword should only be used if the gas and water phases are present in the run, and can therefore also be used with the CO2STORE model. In addition, the keyword must be used in conjunction with the GSF keyword in the PROPS section, that defines the gas relative permeability and gas-water capillary pressure data versus gas saturation for gas-water systems.

Note

WSF is a compositional keyword in the commercial compositional simulator, and will therefore cause an error in the commercial black-oil simulator.

Currently, both the GSF and WSF keywords can only be used with the CO2STORE model.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	SWAT	A columnar vector of real monotonically increasing down the column values starting from zero and terminating at one, that defines the water saturation. The first entry is the connate water saturation Swc and the last entry should be 1.0.			
		dimensionless	dimensionless	dimensionless	None
2	KRW	A columnar vector of real values that are either equal or increasing down the column and that are greater than or equal to zero and less than or equal to one that defines the water relative permeability with respect to gas saturation. Note that the first entry in the column must be zero.			
		dimensionless	dimensionless	dimensionless	None

Notes:

1) The keyword is followed by NTSFUN tables as declared on the TABDIMS keyword in the RUNSPEC section.
2) Each table must contain a minimum of two rows and a maximum of NSSFUN rows as declared on the TABDIMS keyword in the RUNSPEC section.
3) Each table is terminated by a "/" and there is no "/" terminator for the keyword.

Table 8.201: WSF Keyword Description

See also the *GSF - Gas Saturation Function Tables (Gas-Water Systems)* keyword in the PROPS section, that defines the gas relative permeability and gas-water capillary pressure data as a function of gas saturation, for when only the gas and water water phases are present in the model.

Example

         0.700000   0.5000
         1.000000   0.9000             / TABLE NO. 01
```

The example defines two WSF tables for use when only gas and water are present in the run.

8.3.369 ZMFVD – DEFINE COMPOSITIONAL COMPONENTS VERSUS DEPTH

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The ZMFVD keyword defines the compositional component mole fractions, for each component, as a function of depth, as such the keyword should have the same number of component columnar vectors as that declared via the COMPS keyword in the RUNSPEC section, and the NCOMPS keyword in the PROPS section. The keyword should only be used if the CO2STORE and GASWAT keywords in the RUNSPEC section have also be activated for the gas-water two component model.

Note

This is an OPM Flow keyword used with OPM Flow's CO2STORE and GASWAT keywords in the RUNSPEC section, and should not be confused with the more general version of the ZMFVD keyword used in the commercial compositional simulator.

No.	Name	Description			Default
		Field	Metric	Laboratory	
1	DEPTH	A columnar vector of real monotonically increasing down the column values that defines the depth values for the corresponding compositional component mole fractions. The default number of DEPTH values is 20, as defined by the NDRXVD parameter on the EQLDIMS keyword in the RUNSPEC section, and which may be used to reset the number of DEPTH values.			
		feet	m	cm	None
2	ZCOMP	A series of columnar vectors, with each columnar vector representing a compositional component mole fraction as a function of DEPTH. In addition, the sum of the compositional component mole fractions must sum to one for a given DEPTH value, otherwise an error will occur. Secondly, if the composition is independent of depth, then only one single row may be entered. Note that the number of columnar vectors, should be the same as that entered via the NCOMPS keyword in the PROPS section, and the COMPS keyword in the RUNSPEC section. Finally, only the default value of two components are currently supported by OPM Flow.			
		mole fraction	mole fraction	mole fraction	None

Notes:

1) The keyword is terminated by a "/".

Table 8.202: ZMFVD Keyword Description

Example

The following example defines how to confirm a two component formulation, together with defining the names of the composition components, as well as the compositional gradient, to be used with the CO2STORE and GASWAT options.

```

CHAPTER 9: REGIONS SECTION

9.1 INTRODUCTION

The REGIONS section defines how various properties in the PROPS and SOLUTION sections are allocated to individual cells within the model, as well as defining various fluid in-place reporting regions. This is accomplished by assigning an integer value to each cell that represents the data set of the property to be assigned to the grid block.

9.2 DATA REQUIREMENTS

OPM Flow, like most numerical modeling software, uses a default value of one for the various region arrays and thus if there is only one PVT data set for example, then there is no need to define the region array associated with allocating the PVT tables (via the PVTNUM keyword in the REGIONS section), as all cells will be allocated PVT table number one. However, if there are more than one PVT table entered in the PROPS section and PVTNUM is not defined in the model, then PVT tables greater than one will not be used and there will be no warning message indicting the fact.

Table 9.1 summarizes the various property region data and their associated keywords.

No.	REGIONS Keyword	Standard Property Regions	Property Section
1	EQLNUM	*EQLNUM – Define the Equilibration Region Numbers*. Equilibrium region allocation based on the EQUIL keyword in the SOLUTION section.	SOLUTION
2	FIPNUM	*FIPNUM – Define the Fluid In-Place Region Numbers*. Fluid In-Place reporting via the FIPNUM array that divides the model into different fluid in-place reporting regions.	REGION
3	PVTNUM	*PVTNUM – Define the PVT Regions*. PVT table allocation of the DENSITY, PVDG, PVDO, PVTG, PVTO, PVCO, PVTW and ROCK tables	PROPS
4	SATNUM	*SATNUM – Define the Saturation Table Region Numbers*. Saturation (relative permeability) table allocation of the SGFN, SWFN, SOF2, SOF3, SGOF, and SWOF tables. This array is for the standard drainage, as oppose to the imbibition curves, used in all models. There are separate region arrays for alternative relative permeability curves.	PROPS
	Function Specific Regions		
5	ENDNUM	*ENDNUM – Define the End-Point Scaling Depth Region Numbers*. ENPTVD and ENKRVD versus depth table allocation for when ENDSCALE option has been activated in the RUNSPEC section.	PROPS
6	FIP	*FIP – Define the Fluid In-Place Names and Region and Numbers*. Fluid In-Place reporting via the FIP array that divides the model into different fluid in-place reporting regions.	REGION
7	FIPOWG	*FIPOWG – Activate Oil, Gas, and Water FIP Zone Reporting*. Fluid In-Place reporting for the total oil, gas and water in the model. There is no region property array for this keyword, as the simulator calculates the total phase volumes based on the contacts entered via the EQUIL keyword in the SOLUTION section.	REGION
8	HBNUM	*HBNUM – Define Herschel-Bulkley Region Numbers*. Herschel-Bulkley rheological property table region numbers.	PROPS

No.	REGIONS Keyword	Standard Property Regions	Property Section
9	HWSNUM	*HWSNUM – Define the Saturation Table Region Numbers (High Salinity and Water Wet)*. High salinity water wet saturation table allocation using the high salinity water wet saturation SWFN and SOFN tables. This is an alias for the SURFWNUM property region which is also not supported by OPM Flow.	PROPS
10	IBMNUM	*IMBNUM – Define the Imbibition Saturation Table Region Numbers*. Imbibition saturation table allocation of the SWFN, SOF2, SOF3 or SWOF imbibition tables.	PROPS
11	IMBNUMMF	*IMBNUMMF – Define the Imbibition Saturation Table Region Numbers (Matrix-Fracture)*. Imbibition saturation tables region numbers for flow between the matrix and fracture blocks, for when the Hysteresis option has been activated in Dual Porosity or Dual Permeability runs.	PROPS
12	KRNUM	*KRNUM – Define the Directional Saturation Table Region Numbers*. Direction dependent saturation tables region numbers for when Directional Dependent Saturation Function option has been activated by the DIRECT parameter on the SATOPTS	PROPS
13	KRNUMMF	*KRNUMMF – Define the Saturation Table Region Numbers (Matrix-Fracture)*. Drainage saturation tables region numbers for flow between the matrix and fracture blocks in a Dual Porosity or Dual Permeability model.	PROPS
14	LSLTWNUM	*LSLTWNUM – Define the Low Salt Water Wet Saturation Table Region Numbers*. Low salt water wet saturation tables region numbers for when the Low Salinity option for the Brine model and the Surfactant Wettability option have been activated for the model.	PROPS
15	LSNUM	*LSNUM – Define the Low Salt Oil Wet Saturation Table Region Numbers*. Low salt oil wet saturation tables region numbers for the Low Salinity Brine model.	PROPS
16	LWSLTNUM	*LWSLTNUM – Define the Low Salt Oil Wet Saturation Table Region Numbers*. Low salt oil wet saturation table region numbers for the Low Salinity Brine model.	PROPS
17	LWSNUM	*LWSNUM – Define the Low Salt Water Wet Saturation Table Region Numbers*. Low salt water wet saturation table region numbers for when the Low Salinity option for the Brine model and the Surfactant Wettability option have been activated for the model.	PROPS
18	MISNUM	*MISNUM – Define the Miscibility Region Numbers*. Miscible regions based on the TLMIXPAR records when the MISCIBLE or SOLVENT keywords have been activated in the RUNSPEC section.	PROPS
19	OPERNUM	*OPERNUM – Define Regions for Mathematical Operations on Arrays*. OPERATER keyword region numbers that can also be used with the EQUALREG, ADDREG, COPYREG, MULTIREG, MULTREGP and MULTREGT keywords, as well as the OPERATER keyword in calculating various grid properties in the GRID and REGION section.	GRID EDIT PROPS REGION SOLUTION

No.	REGIONS Keyword	Standard Property Regions	Property Section
20	PENUM	*PENUM – Define the Petro-Elastic Region Numbers*. Petro-elastic region numbers for petro-elastic coefficients, bulk modulus functions and shear modulus functions.	PROPS
21	PLMIXNUM	*PLMIXNUM – Define the Polymer Region Numbers*. Polymer region numbers for the mixing tables, and the maximum polymer and salt concentrations for the Polymer option.	PROPS
22	RESIDNUM	*RESIDNUM – Define Vertical Equilibrium Residual Flow Region Numbers* . Vertical Equilibrium residual flow calculation saturation tables or when region numbers for the Vertical Equilibrium option.	PROPS
23	ROCKNUM	*ROCKNUM – Define Rock Compaction Table Region Numbers*. Rock compaction table allocation for when the ROCKCOMP keyword as been activated in the RUNSPEC section, that allocates the ROCKTAB series of tables to a cell.	PROPS
24	SURFNUM	*SURFNUM – Define the Surfactant Miscible Saturation Table Region Numbers*. Surfactant saturation (relative permeability) tables allocation allocating the SWFN, SOF2, SOF3 or SWOF as miscible tables.	PROPS
25	SURFWNUM	*SURFWNUM – Define the Saturation Table Region Numbers (High Salinity and Water Wet)*. High salinity water wet saturation table allocation using the high salinity water wet saturation SWFN and SOFN tables.	PROPS
26	TNUM	*TNUM – Define Passive Tracer Concentration Regions*. Partitioned Tracer option region numbers for this option.	PROPS
27	TRKPF	*TRKPF – Define Partitioned Tracer Regions*. Defines the regions associated with partition tracers and the partitioning tables allocated to grid blocks for when the Partitioned Tracer option has been enabled by the PARTTRAC keyword in the RUNSPEC section.	PROPS
28	WH2NUM	*WH2NUM – Define WAG Hysteresis Saturation Table Region Numbers (Two Phase)*. Two phase Water-Alternating-Gas ("WAG") hysteresis saturation table region numbers for when the hysteresis option has been activated by the WAGHYSTR variable on the SATOPTS keyword in the RUNSPEC.	PROPS
29	WH3NUM	*WH3NUM – Define WAG Hysteresis Saturation Table Region Numbers (Three Phase)*. Three phase WAG hysteresis saturation table region numbers for when the hysteresis option has been activated by the WAGHYSTR variable on the SATOPTS keyword in the RUNSPEC.	PROPS

Notes:

1) Note that not all keywords and features listed above are implemented in OPM Flow. Cells not colored in the No. column indicate the keyword is supported or partially supported by OPM Flow, cells colored gray indicate that the keyword is not applicable and will be ignored by the simulator, and finally, cells colored in orange indicate keywords that are not supported by OPM Flow and will be ignored by the simulator.

2) Note that is common to set the FIPNUM array to be equal to the EQLNUM to have fluid in-place reporting for each equilibrium region, this can be done by using the COPY keyword to copy the EQLNUM array to the FIPNUM array.

Table 9.1: REGION Section Allocation Array Summary

Note

Earth modeling software may export the region arrays to be loaded into the simulator with values starting from zero instead of one. This may result in an error message if these cells are active in the model, if the cells are inactive then the zero values will be ignored by the simulator.

The allocation is based on a complete property data set, that is all the property data associated with a given data set is allocated to the cell. For example, if the fluid properties for the model are the same, (for example, PVTO and PVDG keyword data) but the rock compressibility is varying with depth resulting in, say three different ROCK keyword records, then there has to be three complete data sets in order to allocate the three ROCK records. This would mean that the PVTO and PVDG keywords, in this instance, would have to be repeated three times to match the three ROCK keyword records.

Example SATNUM and EQUIL arrays from the Volve[283] field are displayed in Figure 9.1 and Figure 9.2, respectively.

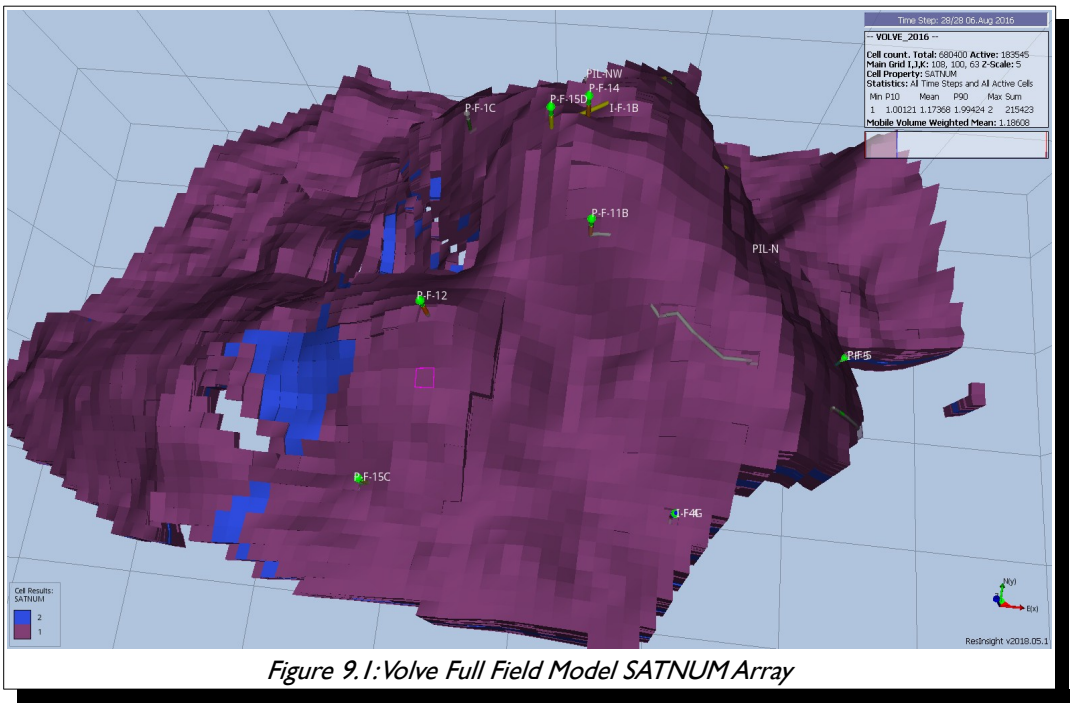

Figure 9.1: Volve Full Field Model SATNUM Array

[283] *The Volve Data was approved for data sharing in 2018 by the initiative of the last Operating company, Equinor and approved by the license partners ExxonMobil E&P Norway AS and Bayerngas Norge AS in the end of 2017.*

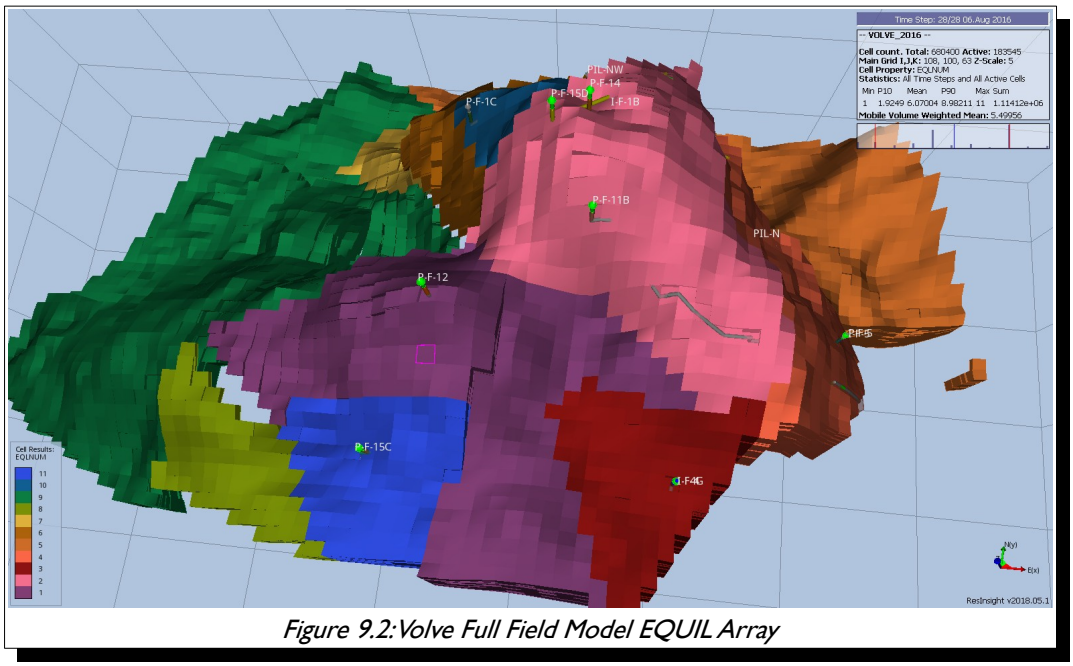

Figure 9.2:Volve Full Field Model EQUIL Array

9.3 KEYWORD DEFINITIONS

9.3.1 ADD – ADD A CONSTANT TO A SPECIFIED ARRAY

The ADD keyword adds a constant to a specified array or part of an array. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the ADD keyword is being applied.

See *ADD – Add a Constant to a Specified Array* in the GRID section for a full description.

9.3.2 ADDREG – ADD A CONSTANT TO AN ARRAY BASED ON A REGION NUMBER

The ADDREG keyword adds a constant to a specified array or part of an array based on cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the ADDREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the ADDREG keyword is being used.

See *ADDREG – Add a Constant to an Array based on a Region Number* in the GRID section for a full description.

9.3.3 BOUNDARY – DEFINE A BOUNDARY BOX FOR PRINTING

The BOUNDARY keyword defines a rectangular grid for printing various arrays to the output print file (*.PRT); thus, avoiding printing all the elements in the selected array.

See *BOUNDARY – Define a Boundary Box for Printing* in the GRID section for a full description.

9.3.4 BOX - DEFINE A RANGE OF GRID BLOCKS TO ENTER PROPERTY DATA

BOX defines a range of grid blocks for which subsequent data is assigned for all the cells in the defined BOX. Note that the BOX grid is reset by the keyword ENDBOX by resetting the current defined BOX to be the whole grid. The keyword can be used for any array and for all grid types.

See *BOX - Define a Range of Grid Blocks to Enter Property Data* in the GRID section for a full description.

9.3.5 COLUMNS – DEFINE INPUT FILE COLUMN MARGINS

The COLUMNS keyword defines the input file column margins; characters outside the margins are ignored by the input parser.

See *COLUMNS – Define Input File Column Margins* in the GLOBAL section for a full description.

9.3.6 COPY – COPY ARRAY DATA TO ANOTHER ARRAY

The COPY keyword copies an array (or part of an array) to another array or part of an array. The arrays can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the COPY keyword is being used.

See *COPY – Copy Array Data to Another Array* in the GRID section for a full description.

9.3.7 COPYBOX – COPY ARRAY DATA DEFINED BY A BOX

The COPYBOX keyword copies an array (or part of an array) to part of the same array. The array can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the COPYBOX keyword is being used.

See *COPYBOX – Copy Array Data Defined by a Box* in the GRID section for a full description.

9.3.8 COPYREG – COPY AN ARRAY TO ANOTHER ARRAY BASED ON A REGION NUMBER

The COPYREG keyword copies a specified array or part of an array based on cells with a specific region number to another array. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the COPYREG keyword is read by the simulator. The property arrays can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the COPYREG keyword is being used.

See *COPYREG – Copy an Array to Another Array based on a Region Number* in the GRID section for a full description.

9.3.9 DEBUG – DEFINE THE DEBUG DATA TO BE PRINTED TO FILE

This keyword defines the debug data to be written to the debug file (*.DBG). This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

See *DEBUG – Define the Debug Data to be Printed to File* in the GLOBAL section for a full description.

9.3.10 ECHO – ACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns on echoing of all the input files to the print file; note that this keyword is activated by default and can subsequently be switched off by the NOECHO activation keyword.

See *ECHO – Activate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

9.3.11 END – DEFINE THE END OF THE INPUT FILE

This keyword marks the end of the input file and can occur in any section. Any keywords and data after the END keyword are ignored.

See *END – Define the End of the Input File* in the GLOBAL section for a full description.

9.3.12 ENDBOX – DEFINE THE END OF THE BOX DEFINED GRID

This keyword marks the end of a previously defined BOX sub-grid as defined by a previously entered BOX keyword. The keyword resets the input grid to be the full grid as defined by the NX, NY, and NZ variables on the DIMENS keyword in the RUNSPEC section.

See *ENDBOX – Define the End of the BOX Defined Grid* in the GRID section for a full description.

9.3.13 ENDFIN – END THE DEFINITION OF A LOCAL GRID REFINEMENT

ENDFIN defines the end of a Cartesian or radial local grid refinement ("LGR") definition and a LGR property definition data set.

See *ENDFIN – End the Definition of a Local Grid Refinement* in the GRID section for a full description.

9.3.14 ENDINC – DEFINE THE END OF AN INCLUDE FILE

This keyword marks the end of an include file specified on the INCLUDE keyword. When the ENDINC keyword is encountered in the INCLUDE file, input data is read from the next keyword in the current file. Any keywords and data after the ENDINC keyword in the INCLUDE file are ignored.

See *ENDINC – Define the End of an Include File* in the GLOBAL section for a full description.

9.3.15 ENDNUM – DEFINE THE END-POINT SCALING DEPTH REGION NUMBERS

Description

The ENDNUM keyword defines the end-point scaling depth table region numbers for each grid block. The end-point scaling depth tables for various regions are defined by the ENPVTD[284] and the ENKRVD[285] keywords in the PROPS section. In the RUNSPEC section the NTENDP variable on the ENDSCALE keyword defines the maximum number of depth tables.

No.	Name	Description	Default
1	ENDNUM	ENDNUM defines an array of positive integers assigning a grid cell to a particular end-point scaling depth table region. The maximum number of ENDNUM regions is set by the NTENDP variable on the ENDSCALE keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a ENDNUM region number then the default value of one will be used.
3) The keyword is terminated by a "/".

Table 9.2: ENDNUM Keyword Description

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

Examples

The example below sets three ENDNUM regions for a 4 x 5 x 2 model.

```
--
--        DEFINE ENDNUM REGIONS FOR ALL CELLS
--
ENDNUM
          2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
          3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          ENDNUM      1             1*  1*   1*  1*   1*  1* / SET REGION 1
          ENDNUM      2             1   2    1   2    1   1  / SET REGION 2
          ENDNUM      3             1   2    1   2    2   2  / SET REGION 3
/
```

[284] *This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.*

[285] *This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.*

9.3.16 ENDSKIP – DEACTIVATE SKIPPING OF KEYWORDS AND INPUT DATA

Turns off skipping of keywords that was activated by the SKIP, SKIP100, or SKIP300 keywords. Note that for each SKIP keyword activated there must be a corresponding ENDSKIP keyword.

See *ENDSKIP – DeActivate Skipping of Keywords and Input Data* in the GLOBAL section for a full description.

9.3.17 EQLNUM – DEFINE THE EQUILIBRATION REGION NUMBERS

Description

The EQLNUM keyword defines the equilibration region numbers for each grid block. The equilibration data for various regions are defined in the SOLUTION section. For example, the EQUIL keyword in the SOLUTION section defines the initial pressures and fluid contacts for each equilibration region identified by the EQLNUM region array.

No.	Name	Description	Default
1	EQLNUM	EQLNUM defines an array of positive integers assigning a grid cell to a particular equilibration region. The maximum number of EQLNUM regions is set by the NTEQUL variable on the EQLDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The EQLNUM and PVTNUM arrays need to be consistent, that is the all cells with the same EQLNUM can only belong to one PVTNUM region.
3) If a cell is not assigned a EQLNUM region number then the default value will be used.
4) The keyword is terminated by a "/".

Table 9.3: EQLNUM Keyword Description

Examples

The example below sets three EQLNUM regions for a 4 x 5 x 2 model.

```
--
--        DEFINE EQLNUM REGIONS FOR ALL CELLS
--
EQLNUM
          2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
          3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          EQLNUM'     1             1*  1*   1*  1*   1*  1* / SET REGION 1
          EQLNUM'     2             1   2    1   2    1   1  / SET REGION 2
          EQLNUM'     3             1   2    1   2    2   2  / SET REGION 3
/
```

9.3.18 EQUALREG – SETS AN ARRAY TO A CONSTANT BY REGION NUMBER

The EQUALREG keyword sets a specified array to a constant for cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the EQUALREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the EQUALREG keyword is being used.

See *EQUALREG – Sets an Array to a Constant by Region Number* in the GRID section for a full description.

9.3.19 EQUALS – SETS A SPECIFIED ARRAY TO A CONSTANT

The EQUALS keyword sets a specified array or part of an array to a constant. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the EQUALS keyword is being used.

See *EQUALS – Sets a Specified Array to a Constant* in the GRID section for a full description.

9.3.20 EXTRAPMS – ACTIVATE EXTRAPOLATION WARNING MESSAGES

The EXTRAPMS keyword activates extrapolation warning messages for when OPM Flow extrapolates the PVT or VFP tables. Frequent extrapolation warning messages should be investigated and resolved as this would indicate possible incorrect data and may result in the simulator extrapolating to unrealistic values.

See *EXTRAPMS – Activate Extrapolation Warning Messages* in the GLOBAL section for a full description.

9.3.21 FILEUNIT – ACTIVATE UNIT CONSISTENCY VERIFICATION

The FILEUNIT keyword defines the units of the of the data set, and is used to verify that the units in the input deck and any associated include files are consistent grid data. The keyword does not provide for the conversion between different sets of units.

See *FILEUNIT – Activate Unit Consistency Checking* in the GRID section for a full description.

9.3.22 FIP – DEFINE THE FLUID IN-PLACE NAMES AND REGION AND NUMBERS

Description

The FIP keyword defines the fluid in-place name and the associated region numbers for each grid block. The simulator can print out summaries of the fluid in-place in each region, the current flow rates between regions, and the cumulative flows between regions. This keyword is not in the standard keyword format due to the fluid in-place name being concatenated to the keyword FIP to fully define the keyword.

Note that the total number of FIP and FIPNUM regions must be defined by the NMFIPR variable on the REGDIMS keyword, or the NTFIP variable on the TABDIMS keyword. Both keywords are in the RUNSPEC section.

No.	Name	Description	Default
1	FIPNAME	A character string of up to eight characters, consisting of FIP as the first three characters followed by up to a five letter character string defining the fluid in-place's name.	None
2	FIPNUM	FIPNUM defines an array of positive integers greater than or equal to one, that assigns a grid cell to a particular fluid in-place region named by FIPNAME. The maximum number of FIP and FIPNUM regions is set by the REGDIMS(NMFIPR) or the TABDIMS(NTFIP) keywords(variables) in the RUNSPEC section. If both REGDIMS(NMFIPR) and TABDIMS(NTFIP) have been defined then the maximum of the two is used.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a FIP region number by the end of the REGION section then the fault value of one will be used.
3) The keyword is terminated by a "/".

Table 9.4: FIP Keyword Description

The keyword behaves the same as the FIPNUM keyword except the full name of the keyword, including the concatenated characters, are used as the property region name. For example, if we wish define a fluid in-place region name called UNIT, then the keyword would be FIPUNIT.

Note

The commercial simulator prints out a fluid in-place report if the FIP option on the RPTSCHED keyword is set equal to three, that is: FIP=3. This option is currently not available in OPM Flow.

The region property data for FIP arrays can be written to the SUMMARY file, and the RSM file if requested, similar to the FIPNUM regions, with some caveats:

1) Only SUMMARY keywords for regions may be used, that is the SUMMARY variable name must begin with the letter R.
2) The SUMMARY variable name must consist of a character string length of exactly five characters, if less than five characters, then the "_" character should be used to fill out the SUMMARY variable name. For example, instead of RPRUNIT, use RPR__UNI, or instead of ROIPUNIT, use ROIP_UNI.

3) Only the first three characters of the FIP region name should be concatenated with the SUMMARY variable name. This means if the FIP region name is UNIT, the FIP keyword would be FIPUNIT; however, to access the regional pressures for FIPUNIT, one should use RPR__UNI, or to access the regional oil in-place one would use ROIP_UNI.

See also the FIPOWG keyword in the REGIONS section that automatically defines the fluid-in-place regions at the start of the run based the gas, oil and water zones at the time the model was initialized.

Example

The example below defines a region name of UNIT and sets three FIPUNIT regions for a 4 x 5 x 2 model.

```
--
--       DEFINE FIPUNIT FIP REGIONS FOR ALL CELLS
--
FIPUNIT
         2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
         3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

The second example is based on the Norne model that defines two FIP regions based on geological layers and numerical layers using the EQUALS keyword.

```
--       FIPGL BASED ON GEOLOGICAL LAYERS
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         FIPGL       1             1  46    1 112    1   3   /  Garn
         FIPGL       2             1  46    1 112    4   4   /  Not
         FIPGL       3             1  46    1 112    5   5   /  Ile 2.2
         FIPGL       4             1  46    1 112    6   8   /  Ile 2.1
         FIPGL       5             1  46    1 112    9  11   /  Ile 1
         FIPGL       6             1  46    1 112   12  12   /  Tofte 2.2
         FIPGL       7             1  46    1 112   13  15   /  Tofte 2.1
         FIPGL       8             1  46    1 112   16  18   /  Tofte 1
         FIPGL       9             1  46    1 112   19  22   /  Tilje
--
--       FIPNL BASED ON NUMERICAL LAYERS
--
         FIPNL       1             1  46    1 112    1   1   /  Garn 3
         FIPNL       2             1  46    1 112    2   2   /  Garn 2
         FIPNL       3             1  46    1 112    3   3   /  Garn 1w
         FIPNL       4             1  46    1 112    4   4   /  Not
         FIPNL       5             1  46    1 112    5   5   /  Ile 2.2
         FIPNL       6             1  46    1 112    6   6   /  Ile 2.1.3
         FIPNL       7             1  46    1 112    7   7   /  Ile 2.1.2
         FIPNL       8             1  46    1 112    8   8   /  Ile 2.1.1
         FIPNL       9             1  46    1 112    9   9   /  Ile 1.3
         FIPNL      10             1  46    1 112   10  10   /  Ile 1.2
         FIPNL      11             1  46    1 112   11  11   /  Ile 1.1
         FIPNL      12             1  46    1 112   12  12   /  Tofte 2.2
         FIPNL      13             1  46    1 112   13  13   /  Tofte 2.1.3
         FIPNL      14             1  46    1 112   14  14   /  Tofte 2.1.2
         FIPNL      15             1  46    1 112   15  15   /  Tofte 2.1.1
         FIPNL      16             1  46    1 112   16  16   /  Tofte 1.2.2
         FIPNL      17             1  46    1 112   17  17   /  Tofte 1.2.1
         FIPNL      18             1  46    1 112   18  18   /  Tofte 1.1
         FIPNL      19             1  46    1 112   19  19   /  Tilje 4
         FIPNL      20             1  46    1 112   20  20   /  Tilje 3
         FIPNL      21             1  46    1 112   21  21   /  Tilje 2
         FIPNL      22             1  46    1 112   22  22   /  Tilje 1
/
```

Then in order to get the reservoir pressure for the regions and the in-place oil volumes SUMMARY variables written to the SUMMARY file, one would use the following SUMMARY variable names in the SUMMARY section

```
-- ==========================================================================
--
-- SUMMARY SECTION
--
-- ==========================================================================
SUMMARY
--       FIP REGION REPORTING
--
ROIP_GL
/
ROIP_NL
/
RPR__GL
/
RPR__NL
/
```

Notice how the "_" character has been used to extend the SUMMARY variable name to five characters.

9.3.23 FIPNUM – DEFINE THE FLUID IN-PLACE REGION NUMBERS

Description

The FIPNUM keyword defines the fluid in-place region numbers for each grid block. The simulator can print out summaries of the fluid in-place in each region, the current flow rates between regions, and the cumulative flows between regions.

Note that the total number of FIPNUM and FIP regions must be defined by the NMFIPR variable on the REGDIMS keyword, or the NTFIP variable on the TABDIMS keyword. Both keywords are in the RUNSPEC section.

No.	Name	Description	Default
1	FIPNUM	FIPNUM defines an array of positive integers greater than or equal to one, that assigns a grid cell to a particular fluid in-place region. The maximum number of FIPNUM and FIP regions is set by the REGDIMS(NMFIPR) or the TABDIMS(NTFIP) keywords(variables) in the RUNSPEC section. If both REGDIMS(NMFIPR) and TABDIMS(NTFIP) have been defined then the maximum of the two is used.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If acell is not assigned a FIPNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.5: FIPNUM Keyword Description

Note

In most simulation models the FIPNUM array is used to define various regions in the model for fluid in-place reporting and to identify (or report) the flow between the different regions. When calibrating a model's in-place volumes it would be useful to use the FIPNUM array combined with the MULTREGP keyword to accomplish this. However, the FIPNUM array cannot be used in the GRID section.

A work around is to:

1) Use the FIPNUM array but change the keyword to MULTNUM and incorporate this keyword or INCLUDE file in the GRID section.
2) Use the MULTREGP to calibrate the fluid in-place volumes for the various regions.
3) In the REGIONS section, use the COPY keyword to copy the MULTNUM array to the FIPNUM array.

The above work flow will ensure that both arrays and the reporting of fluid in-place regions are consistent.

Examples

The example below sets three FIPNUM regions for a 4 x 5 x 2 model.

```
--
--       DEFINE FIPNUM REGIONS FOR ALL CELLS
--
FIPNUM
         2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
         3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         FIPNUM     1            1*  1*   1*  1*    1*  1* / SET REGION 1
         FIPNUM     2            1   2    1   2     1   1  / SET REGION 2
         FIPNUM     3            1   2    1   2     2   2  / SET REGION 3
/
```

9.3.24 FIPOWG – ACTIVATE OIL, GAS, AND WATER FIP ZONE REPORTING

Description

The FIPOWG keyword activates automatic fluid in-place reporting based on the initial oil, gas and water zones defined by the initial equilibration. The fluid contacts on the EQUIL keyword in the SOLUTION section determine the reporting fluid category a grid cell belongs to. For example all grid cells with depths above the gas-oil contact on the EQUIL keyword will be assigned to the gas zone and reported accordingly. Similarly, grid cells with depths between the gas-oil contact and the water-oil contact will be assigned to the oil zone. And finally, grid cells with depths below the oil-water contact will be assigned to the water zone. The simulator can print out summaries of the fluid in-place in each region, the current flow rates between regions, and the cumulative flows between regions.

Note that the total number of FIP and FIPNUM regions must be defined by the NMFIPR variable on the REGDIMS keyword in the RUNSPEC section.

There is no data required for this keyword.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Example

```
--
--       ACTIVATE OIL, GAS, AND WATER FIP ZONE REPORTING
--
FIPOWG
```

The above example switches on automatic fluid in-place reporting based on the initial oil, gas and water zones defined by the initial equilibration.

9.3.25 FORMFEED – DEFINED THE PRINT FILE FORM-FEED CHARACTER

The FORMFEED keyword defines the form-feed character, or carriage control character, for the output print (*.PRT) run summary (*.RSM) files. The keyword should be place at the very top of the input file.

See *FORMFEED – Defined the Print File Form-Feed Character* in the GLOBAL section for a dull description.

9.3.26 GETDATA – LOAD AND ASSIGN DATA ARRAY FROM INIT OR RESTART FILE

The GETDATA keyword loads a data array from a previously generated INIT or RESTART file and assigns the loaded array to either same array in the run or another array name.

See *GETDATA – Load and Assign Data Array from INIT or RESTART Files* in the GRID section for a full description.

9.3.27 HA – HISTORY MATCH END-POINT GRADIENT ADDITIVE MODIFIER

The HA series of keywords defines the history match end-point gradient parameters used to set the additive cumulative end point data, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section.

See *HA – History Match End-Point Gradient Additive Modifier* in the PROPS section for a complete description.

9.3.28 HBNUM – DEFINE HERSCHEL-BULKLEY REGION NUMBERS

Description

The HBNUM keyword defines the Herschel-Bulkley rheological property table region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which table of Herschel-Bulkley rheological property data is assigned to a grid block, for when the Polymer option has been invoked via the POLYMER keyword in the RUNSPEC section and the Non-Newtonian Fluid phase has been declared active by the NNEWTF keyword, also in the RUNSPEC section. The FHERCHBL keyword in the PROPS section is used to specify the Herschel-Bulkley rheological property table data.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

9.3.29 HM – HISTORY MATCH REGION GRADIENT PARAMETERS

Description

The HM series of keywords in the REGION section defines the history match gradient regions and sub-regions, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

For grid properties, the region name (or region property array) is based on the property arrays defined in Table 9.6.

Property Array	Region Name	Grid Property Data Desription
PERMX	HMPERMX	Permeability multipliers in the x-direction.
PERMXY	HMPRMXY	Permeability multipliers in the x-direction and y-direction
PERMY	HMPERMY	Permeability multipliers in the y-direction.
PERMZ	HMPERMZ	Permeability multipliers in the z-direction.
PORV	HMPORV	Pore volume multiplier
SIGMA	HMSIGMA	Dual porosity and/or dual permeability SIGMA multiplier
TRANX	HMTRANX	Transmissibility multipliers in the x-direction.
TRANXY	HMTRNXY	Transmissibility multipliers in the x-direction and y-direction
TRANY	HMTRANY	Transmissibility multipliers in the y-direction.
TRANZ	HMTRANZ	Transmissibility multipliers in the z-direction.

Table 9.6: HM Region Grid Gradient Parameter Keyword List

In addition, if the End-Point Scaling option has been activated by the ENDSCALE keyword in the RUNSPEC section, then the history match gradient regions and sub-regions for the end-point data can be specified. In this the keyword consists of the first two characters of "HM" followed by the end-point keyword (Table 9.7), for example, HMSWL.

Type	End-Point Keyword	Oil-Water End-Point Definitions
Saturation	HMSWL	Connate water saturation, that is the smallest water saturation in a water saturation function table.
	HMSWCR	Critical water saturation, that is the largest water saturation for which the water relative permeability is zero.
	HMSOWCR	Critical oil-in-water saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-water system.

Type	End-Point Keyword	Oil-Water End-Point Definitions
Relative Permeability	HMKRW	Relative permeability of water at the maximum water saturation (normally the maximum water saturation is one).
	HMKRO	Relative permeability of oil at the maximum oil saturation.
	HMKRWR	Relative permeability of water at the residual oil saturation or the residual gas saturation in a gas-water run.
	HMKRORW	Relative permeability of oil at the critical water saturation.
Capillary Pressure	HMSWLPC	Capillary pressure connate water saturation, that is the smallest water saturation in a water saturation function table.
Type	**End-Point Keyword**	**Gas-Oil End-Point Definitions**
Saturation	HMSGL	Connate gas saturation, that is the smallest gas saturation in a gas saturation function table.
	HMSGCR	Critical gas saturation, that is the largest gas saturation for which the gas relative permeability is zero.
	HMSOGCR	Critical oil-in-gas saturation, that is the largest oil saturation for which the oil relative permeability is zero in an oil-gas-connate water system.
Relative Permeability	HMKRG	Relative permeability of gas at the maximum gas saturation.
	HMKRGR	Relative permeability of gas at the residual oil saturation or the critical water saturation in a gas-water run.
	HMKRORG	Relative permeability of oil at the critical gas saturation.
Capillary Pressure	HMSGLPC	Capillary pressure connate gas saturation, that is the smallest gas saturation in a gas saturation function table.

Table 9.7: HM Region End-Point Gradient Parameter Keyword List

9.3.30 HMPROPS – HISTORY MATCH END-POINT SECTION START

HMPROPS defines the start of a history match end-points section, for when the History Match Gradient option has been activated by the HMDIMS keyword in the RUNSPEC section. In addition, the End-Point Scaling option must also be activated by the ENDSCALE keyword which is also in the RUNSPEC section. The keyword allows for the BOX, EQUALS, COPY, MINVALUE, MAXVALUE and ADD keywords to be used with the HM series of keywords that reference the end-point scaling arrays, that is: HMKRG, HMKRGR, HMKRO, HMKRORG, HMKRORW, HMKRW, HMKRWR, HMPCW, HMPCG, HMSGCR, HMSOWCR, HMSOGCR, HMSWCR, and HMSWL.

See *HMPROPS – History Match End-Point Section Start* in the PROPS section for a full description.

9.3.31 HWSNUM – DEFINE THE SATURATION TABLE REGION NUMBERS (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The HWSNUM keyword defines the saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the mode, for when the Surfactant Wettability option has been selected. The keyword may also be used with the Low Salt Brine option, in this case the water wet curves are calculated as a function of the low and high water wet salinity curves. The region number specifies which set of relative permeability tables are used to calculate the relative permeability and capillary pressure in a grid block. Note that the keyword is obligatory if the SURFACTW keyword in the RUNSPEC section has been used to invoke the Surfactant Wettability option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	HWSNUM	HWSNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of HWSNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a SATNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.8: HWSNUM Keyword Description

Examples

The example below sets three HWSNUM regions for a 4 x 5 x 2 model.

```
--
--        DEFINE HWSNUM REGIONS FOR ALL CELLS
--
HWSNUM
         2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
         3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--        ARRAY       CONSTANT     ---------- BOX ---------
--                                 I1  I2   J1  J2   K1  K2
EQUALS
         HWSNUM      1            1*  1*   1*  1*   1*  1* / SET REGION 1
         HWSNUM      2            1   2    1   2    1   1  / SET REGION 2
         HWSNUM      3            1   2    1   2    2   2  / SET REGION 3
/
```

9.3.32 IMBNUM – DEFINE THE IMBIBITION SATURATION TABLE REGION NUMBERS

Description

The IMBNUM keyword defines the imbibition saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of relative permeability tables (SGFN, SWFN, SOF2, SOF3, SOF32D, SGOF, SLGOF and SWOF) are used to calculate the relative permeability and capillary pressure in a grid block.

No.	Name	Description	Default
1	IMBNUM	IMBNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of IMBNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The keyword is terminated by a "/".
3) If a cell is not assigned an IMBNUM region then the default value of one will be used.

Table 9.9: IMBNUM Keyword Description

In addition, saturation table assignment may be directional dependent in which case the directional dependent versions of the aforementioned array should be used, that is IMBNUMX, IMBNUMY and IMBNUMZ instead of IMBNUM. There is also the facility to make the directional end-point scaling reversible or non-reversible and if the non-reversible option is selected, the non-reversible versions of the aforementioned arrays should be used, that is IMBNUMX, IMBNUMX-, IMBNUMY, IMBNUMY-, IMBNUMZ and IMBNUMZ-, instead of the IMBNUM keyword. For reference, see *Error: Reference source not found*, that lists the various keywords that may be used with directional dependent relative permeability tables.

Note, currently IMBNUMX-, IMBNUMY-, and IMBNUMZ- are not supported.

Example

The example below sets three IMBNUM regions for a 4 x 5 x 2 model using the EQUALS keyword.

```
--
--        ARRAY        CONSTANT      ---------- BOX ---------
--                                    I1   I2    J1   J2    K1   K2
EQUALS
          IMBNUM       1             1*   1*    1*   1*    1*   1* / SET REGION 1
          IMBNUM       2             1    2     1    2     1    1  / SET REGION 2
          IMBNUM       3             1    2     1    2     2    2  / SET REGION 3
/
```

9.3.33 IMBNUMMF – DEFINE THE IMBIBITION SATURATION TABLE REGION NUMBERS (MATRIX-FRACTURE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The IMBNUMMF keyword defines the imbibition saturation tables (relative permeability and capillary pressure tables) region numbers for flow between the matrix and fracture blocks, for when the HYSTER option on the SATOPTS keyword has been invoked to activate the Hysteresis option, and the Dual Porosity or Dual Permeability models have been activated via the DUALPORO or DUALPERM keywords. All keywords are in the RUNSPEC section.

The region number specifies which set of relative permeability tables (SGFN, SWFN, SOF2, SOF3, SOF32D, SGOF, SLGOF and SWOF) are used to calculate the relative permeability and capillary pressure between the matrix and fracture blocks. The keyword is optional and any cell not assigned a value will use the assignment from the IMBNUM array.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

9.3.34 IMPORT – IMPORT GRID FILE DATA AT THE CURRENT POSITION

The IMPORT keyword informs the simulator to continue reading input data from the specified IMPORT file. When the end of the IMPORT file is reached, input data is read from the next keyword in the current file. Normally IMPORT files are generated by grid pre-processing software and the keyword allows for both formatted and unformatted (binary) files to be loaded.

See *IMPORT – Import Grid File Data at the Current Position* in the GRID section for a full description.

9.3.35 INCLUDE – LOAD ANOTHER DATA FILE AT THE CURRENT POSITION

The INCLUDE keyword informs OPM Flow to continue reading input data from the specified INCLUDE file. When the end of the INCLUDE file is reached, or the ENDINC keyword is encountered in the included file, input data is read from the next keyword in the current file.

See *INCLUDE – Load Another Data File at the Current Position* in the GLOBAL section for a full description.

9.3.36 KRNUM – DEFINE THE DIRECTIONAL SATURATION TABLE REGION NUMBERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The KRNUM keyword defines the direction dependent saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block face, as such there must be one entry for each cell in the model. The region number specifies which set of relative permeability tables (SGFN, SWFN, SOF2, SOF3, SOF32D, SGOF, SLGOF and SWOF) are used to calculate the relative permeability and capillary pressure in a grid block. The keyword should only be used if Directional Dependent Saturation Function option has been activated by the DIRECT parameter on the SATOPTS keyword in the RUNSPEC section. Otherwise the standard none directional relative permeability curves should be assigned by the SATNUM keyword in the REGIONS section.

This keyword is not in the standard keyword format due to the cell face (X, X+, Y, Y+, Z, and Z+ for Cartesian grids and R, R+, T, T+ for radial grids) being concatenated to the keyword KRNUM to fully define the keyword.

No.	Name	Description	Default
1	KRNUM	KRNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of KRNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a KRNUM region then the default value of one will be used.
3) The keyword is terminated by a "/".

Table 9.10: KRNUM Keyword Description

If the Directional Dependent Saturation Function option has been activated by the DIRECT parameter on the SATOPTS keyword in the RUNSPEC section, then the KRNUMX, KRNUMY and KRNUMZ form of the keyword should be used. Secondly, if the Non-Reversible End-Point Scaling option is selected by the IRREVERS parameter on the SATOPTS keyword in the RUNSPEC section, then the non-reversible versions of the KRNUM should be used, that is KRNUMX, KRNUMX-, KRNUMY, KRNUMY-, KRNUMZ and KRNUMZ-. For reference, see *Error: Reference source not found*, that lists the various keywords that may be used with directional dependent relative permeability tables.
Note, currently KRNUMX-, KRNUMY-, and KRNUMZ- are not supported.

Example

The example below sets the directional saturation tables in all three directions using the EQUALS keyword.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          KRNUMX      1             1*  1*   1*  1*   1*  1* / SET X-DIR TABLES
          KRNUMY      2             1*  1*   1*  1*   1*  1* / SET Y-DIR TABLES
          KRNUMZ      3             1*  1*   1*  1*   1*  1* / SET Z-DIR TABLES
/
```

9.3.37 KRNUMMF – DEFINE THE SATURATION TABLE REGION NUMBERS (MATRIX-FRACTURE)

Description

The KRNUMMF keyword defines the drainage saturation tables (relative permeability and capillary pressure tables) region numbers for flow between the matrix and fracture blocks, for when the Dual Porosity or Dual Permeability models have been activated via the DUALPORO or DUALPERM keywords in the RUNSPEC section.

The region number specifies which set of relative permeability tables (SGFN, SWFN, SOF2, SOF3, SOF32D, SGOF, SLGOF and SWOF) are used to calculate the relative permeability and capillary pressure between the matrix and fracture blocks. The keyword is optional and any cell not assigned a value will use the assignment from the SATNUM array.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

9.3.38 LSLTWNUM – DEFINE THE LOW SALT WATER WET SATURATION TABLE REGION NUMBERS

Description

The LSLTWNUM keyword defines the saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of relative permeability tables (SWFN, SOF3 and related keywords) are used to calculate the relative permeability and capillary pressure in a grid block. The keyword should only be used if the Low Salinity option for the Brine model and the Surfactant Wettability option have been activated by the LOWSALT and SURFACTW keywords, respectively, in the RUNSPEC section.

The water wet curves are calculated as a weighted average of the low salinity saturation tables (allocated by this keyword) and the high salinity water wet saturation tables (allocated by the SURFWNUM keyword in the REGIONS section), using the weights provided by the LSALTFNC keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	LSLTWNUM	LSLTWNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of LSLTWNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a LSLTWNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.11: LSLTWNUM Keyword Description

Example

The example below sets three LSLTWNUM regions for the model.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          LSLTWNUM    1             1*  1*   1*  1*   1*  1* / SET REGION 1
          LSLTWNUM    2             1   2    1   2    1   1  / SET REGION 2
          LSLTWNUM    3             1   2    1   2    2   2  / SET REGION 3
/
```

9.3.39 LSNUM – DEFINE THE LOW SALT OIL WET SATURATION TABLE REGION NUMBERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LSNUM keyword defines the saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of relative permeability tables (SWFN, SOF3 and related keywords) are used to calculate the relative permeability and capillary pressure in a grid block. The keyword should only be used if the Low Salinity option for the Brine model has been activated in the RUNSPEC section using the LOWSALT keyword.

The oil wet curves are calculated as a weighted average of the low salinity saturation tables (allocated by this keyword) and the high salinity oil wet saturation tables (allocated by the SATNUM keyword), using the weights provided by the LSALTFNC keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	LSNUM	LSNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of LSNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a LSNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.12: LSNUM Keyword Description

If the Surfactant Wettability option have been activated by the SURFACTW keyword, the LSNUM tables correspond to the immiscible low salinity curves.

Example

The example below sets three LSNUM regions for the model.

```
--
--        ARRAY       CONSTANT     ---------- BOX ---------
--                                 I1  I2   J1  J2   K1  K2
EQUALS
          LSNUM       1            1*  1*   1*  1*   1*  1* / SET REGION 1
          LSNUM       2            1   2    1   2    1   1  / SET REGION 2
          LSNUM       3            1   2    1   2    2   2  / SET REGION 3
/
```

9.3.40 LWSLTNUM – DEFINE THE LOW SALT OIL WET SATURATION TABLE REGION NUMBERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LWSLTNUM keyword defines the saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of relative permeability tables (SWFN, SOF3 and related keywords) are used to calculate the relative permeability and capillary pressure in a grid block. The keyword should only be used if the Low Salinity option for the Brine model has been activated by the LOWSALT kwyword in the RUNSPEC section.

The oil wet curves are calculated as a weighted average of the low salinity saturation tables (allocated by this keyword) and the high salinity oil wet saturation tables (allocated by the SATNUM keyword in the REGIONS section), using the weights provided by the LSALTFNC keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	LWSLTNUM	LWSLTNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of LSLTWNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a LWSLTNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.13: LWSLTNUM Keyword Description

Example

The example below sets three LWSLTNUM regions for the model.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          LWSLTNUM    1             1*  1*   1*  1*   1*  1* / SET REGION 1
          LWSLTNUM    2             1   2    1   2    1   1  / SET REGION 2
          LWSLTNUM    3             1   2    1   2    2   2  / SET REGION 3
/
```

9.3.41 LWSNUM – DEFINE THE LOW SALT WATER WET SATURATION TABLE REGION NUMBERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The LWSNUM keyword defines the saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of relative permeability tables (SWFN, SOF3 and related keywords) are used to calculate the relative permeability and capillary pressure in a grid block. The keyword should only be used if the Low Salinity option for the Brine model and the Surfactant Wettability option have been activated by the LOWSALT and SURFACTW keywords, respectively, in the RUNSPEC section.

The water wet curves are calculated as a weighted average of the low salinity saturation tables (allocated by this keyword) and the high salinity water wet saturation tables (allocated by the HWSNUM keyword), using the weights provided by the LSALTFNC keyword in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	LWSNUM	LWSNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of LWSNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a LWSNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.14: LWSNUM Keyword Description

The HWSNUM allocated tables correspond to the immiscible high salinity water wet curves.

Example

The example below sets three LWSNUM regions for the model.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          LWSNUM      1             1*  1*   1*  1*   1*  1* / SET REGION 1
          LWSNUM      2             1   2    1   2    1   1  / SET REGION 2
          LWSNUM      3             1   2    1   2    2   2  / SET REGION 3
/
```

9.3.42 MESSAGE – OUTPUT USER MESSAGE

The MESSAGE keyword outputs a user message to the terminal, as well as to the print (*.PRT) and debug (*.DBG) files. Note this is different to the MESSAGES keyword, that defines OPM Flows message print limits and stop limits generated by the simulator.

See *MESSAGE – Output User Message* in the GLOBAL section for a full description.

9.3.43 MESSAGES – DEFINE MESSAGE PRINT LIMITS AND STOP LIMITS

The MESSAGES keyword defines the print and stops levels for various messages. The "print limits" set the maximum number of messages that will be printed, after which no more messages will be printed and the "stop limits" terminate the run when these limits are exceeded. There are six levels of message that increase in severity from informative all the way to programming errors, as outlined in Error: Reference source not found.

See *MESSAGES – Define Message Print Limits and Stop Limits* in the GLOBAL section for a full description.

9.3.44 MISNUM – DEFINE THE MISCIBILITY REGION NUMBERS

Description

The MISNUM keyword defines the miscibility region number mixing tables as defined by the TLMIXPAR keyword in the PROPS section, for when the miscibility option has been activated by the MISCIBLE keyword in the RUNSPEC section. MISNUM also allocates miscible residual oil saturation versus water saturation tables (SORWMIS keyword in the PROPS section) used to calculate the relative permeability and PVT properties for a grid cell.

Note that although this keyword can only be used when the miscibility option is active, it is not necessary to use this keyword even if the MISCIBLE keyword in the RUNSPEC has been activated as the default value of one will be applied to all grid blocks. Secondly, a value of zero for a grid cell results in immiscible fluids in that grid cell.

No.	Name	Description	Default
1	MISNUM	MISNUM defines an array of positive integers greater than or equal to zero, that assign a grid cell to a particular table of mixing parameters as defined by the TLMIXPAR and SORWMIS keywords. A value of zero sets the fluids within a grid cell to be immiscible. The maximum number of MISNUM regions is set by the NTMIS variable on the MISCIBLE keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a MISNUM region then the default value of one will be used.
3) The keyword is terminated by a "/".

Table 9.15: MISNUM Keyword Description

See also the TLMIXPAR and SORWMIS keyword in the PROPS section.

Example

The example below sets three MISNUM regions in the model on a layer by layer basis, using the EQUALS keyword.

```
--
--        ARRAY        CONSTANT      ---------- BOX ---------
--                                    I1   I2    J1   J2    K1   K2
EQUALS
          MISNUM       1             1*   1*    1*   1*    1    12 / SET REGION 1
          MISNUM       2             1*   1*    1*   1*    13   55 / SET REGION 2
          MISNUM       3             1*   1*    1*   1*    56  120 / SET REGION 3
/
```

9.3.45 MULTIPLY – MULTIPLY A SPECIFIED ARRAY BY A CONSTANT

The MULTIPLY keyword multiplies a specified array or part of an array by a constant. The constant can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

See *MULTIPLY – Multiply a Specified Array by a Constant* in the GRID section for a full description.

9.3.46 MULTIREG – MULTIPLY AN ARRAY BY A CONSTANT BASED ON A REGION NUMBER

The MULTIREG keyword multiplies an array or part of an array by a constant for cells with a specific region number. The region number array can be FLUXNUM, MULTNUM or OPERNUM and these arrays must be defined and be available before the MULTIREG keyword is read by the simulator. The constant can be real or integer depending on the property array type; however, the property arrays that can be operated on is dependent on which section the MULTIREG keyword is being used.

See *MULTIREG – Multiply an Array by a Constant based on a Region Number* in the GRID section for a full description.

9.3.47 NOECHO – DEACTIVATE ECHOING OF USER INPUT FILES TO THE PRINT FILE

Turns off echoing of all the input files to the print file. Note by default echoing of the inputs files is active. but can subsequently be switched off by the NOECHO activation keyword.

See *NOECHO – Deactivate Echoing of User Input Files to the Print File* in the GLOBAL section for a full description.

9.3.48 NOWARN – DEACTIVATE WARNING MESSAGES

Turns off warning messages to be printed to the print file; note that this keyword is deactivated by default and can subsequently be switched off by the WARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN.

See *NOWARN – Deactivate Warning Messages* in the GLOBAL section for a full description.

9.3.49 OPERATE – DEFINE MATHEMATICAL OPERATIONS ON ARRAYS

This keyword, OPERATE, defines mathematical operations on property arrays (NTG, PORO etc.) and optionally using another property array as input to the function. The keyword allows for various mathematical functions and their associated variables to be defined and applied to the selected array data. Input constants can be real or integer depending on the array type; however, the arrays that can be operated on is dependent on which section the keyword is being used.

See *OPERATE – Define Mathematical Operations on Arrays* in the GRID section for a full description.

9.3.50 OPERATER – DEFINE MATHEMATICAL OPERATIONS ON ARRAYS BY REGION

This keyword defines the mathematical operations on arrays for specific regions in the commercial simulator and is currently not supported by OPM Flow. However, similar functionality is provided by the ADD and MULTIPLY keywords.

See *OPERATER – Define Mathematical Operations on Arrays by Region* in the GRID section for a full description.

9.3.51 OPERNUM – DEFINE REGIONS FOR MATHEMATICAL OPERATIONS ON ARRAYS

This keyword defines the OPERATE region numbers for each grid block. The OPERATE keyword defines mathematical operations on arrays in the commercial simulator and is currently not supported by OPM Flow. However, similar functionality is provided by the ADD and MULTIPLY keywords combined with MULTNUM region array.

See *OPERNUM – Define Regions for Mathematical Operations on Arrays* in the GRID section for a full description.

9.3.52 PENUM – DEFINE THE PETRO-ELASTIC REGION NUMBERS

Description

The PENNUM keyword defines the petro-elastic region number for each grid block that is used to assign the of petro-elastic coefficients, bulk modulus functions and shear modulus functions as defined by the PECOEFS, PEKTAB and PEGTAB series of keywords in the PROPS section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

9.3.53 PLMIXNUM – DEFINE THE POLYMER REGION NUMBERS

Description

The PLMIXNUM keyword defines the polymer region number for each grid block that is used to assign the mixing tables as well as the maximum polymer and salt concentrations, as defined by the PLMIXPAR and PLYMAX keywords in the PROPS section, for when the polymer option has been activated by the POLYMER keyword in the RUNSPEC section.

The maximum polymer concentration and the associated salt concentration are declared on the PLYMAX keyword.

No.	Name	Description	Default
1	PLMIXNUM	PLMIXNUM defines an array of positive integers greater than or equal to one, that assign a grid cell to a particular table of mixing parameters as defined by the PLMIXPAR and PLYMAX keywords. The maximum number of PLMIXNUM regions is set by the NPLMIX variable on the REGDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a PLMIXNUM region then the default value of one will be used.
3) The keyword is terminated by a "/".

Table 9.16: PLMIXNUM Keyword Description

See also the PLYADS, PLYADSS, PLYDHLF, PLYMAX, PLYROCK, PLYSHEAR, PLYSHLOG and PLYVISC keywords in the PROPS section.

Example

The example below sets three PLMIXNUM regions in the model on a layer by layer basis, using the EQUALS keyword.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          PLMIXNUM      1           1*  1*   1*  1*   1   12 / SET REGION 1
          PLMIXNUM      2           1*  1*   1*  1*   13  55 / SET REGION 2
          PLMIXNUM      3           1*  1*   1*  1*   56 120 / SET REGION 3
/
```

9.3.54 PVTNUM – DEFINE THE PVT REGIONS

Description

The PVTNUM keyword defines the PVT region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of PVT tables (DENSITY, PVDG, PVDO, PVTG, PVTO, PVCO, PVTW and ROCK) are used to calculate the PVT properties in a grid block.

No.	Name	Description	Default
1	PVTNUM	PVTNUM defines an array of positive integers assigning a grid cell to a particular PVT region. The maximum number of PVTNUM regions is set by the NTPVT variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) The EQULNUM and PVTNUM arrays need to be consistent, that is the all cells with the same PVTNUM can only belong to one EQLNUM region.
3) If a cell is not assigned a PVTNUM region then the default value will be used.
4) The keyword is terminated by a "/".

Table 9.17: PVTNUM Keyword Description

Note

Care should be taken that cells in different PVTNUM regions are not in communication, since the fluid properties are associated with a cell. If for example, a rbbl or a rm3 of oil flows from PVTNUM region 1 to PVTNUM region 2, then the oil properties of that oil will change from the PVT 1 data set to the PVT data set 2. This will result in material balance errors, that may or may not cause numerical issues.

To avoid this one should use the MULTNUM (or FLUXNUM, or OPERNUM) array with the MULTREGT array to ensure that the various PVTNUM regions are not in communication.

Examples

The example below sets three PVTNUM regions for a 4 x 5 x 2 model.

```
--
--       DEFINE PVTNUM REGION FOR ALL CELLS
--
PVTNUM
         2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
         3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         PVTNUM      1            1*  1*   1*  1*   1*  1* / SET REGION 1
         PVTNUM      2            1   2    1   2    1   1  / SET REGION 2
         PVTNUM      3            1   2    1   2    2   2  / SET REGION 3
/
```

There third example shows how to ensure the various PVT regions are isolated. First of all define the MULTNUM array in the GRID section and ensure all the regions are isolated.

```
-- ======================================================================
--
-- GRID SECTION
--
-- ======================================================================
GRID
--
--       ARRAY       CONSTANT     ---------- BOX ---------
--                                I1  I2   J1  J2   K1  K2
EQUALS
         MULTNUM     1            1*  1*   1*  1*   1*  1* / SET REGION 1
         MULTNUM     2            1   2    1   2    1   1  / SET REGION 2
         MULTNUM     3            1   2    1   2    2   2  / SET REGION 3
/
--
--       SET TRANSMISSIBILITES ACROSS DIFFERENT RESERVOIRS TO ZERO TO ISOLATE
--       RESERVOIRS
--
--       REGION   REGION   TRANS   DIREC   NNC    REGION ARRAY
--       FROM     TO       MULT    OPT     OPTS   M / F / O
MULTREGT
         1*       1*       0.0     1*     'ALL'   M        / ALL REGIONS SEALED
/
```

Then in the REGIONS section copy the MULTNUM array to the PVTNUM array.

```
-- ======================================================================
--
-- REGIONS SECTION
--
-- ======================================================================
REGIONS

--
--       COPY AN ARRAY TO ANOTHER ARRAY BASED ON A REGION NUMBER
--
--       ARRAY     ARRAY     REGION   REGION ARRAY
--       FROM      TO        NUMBER    M / F / O
COPYREG
         MULTNUM   PVTNUM    1         M                  / COPY MULT TO PVT 1
         MULTNUM   PVTNUM    2         M                  / COPY MULT TO PVT 2
         MULTNUM   PVTNUM    3         M                  / COPY MULT TO PVT 3
/
```

All the separate PVT regions are now isolated.

9.3.55 PYEND – END THE DEFINITION OF A PYINPUT SECTION

The PYINPUT and PYEND keywords are a part of OPM Flow's Python scripting facility that processes standard Python commands that can be used to manipulate and define the simulators input parameters during processing of the input deck. The main purpose of the facility is to script the construction of the various keywords. A PYINPUT Definition Section is terminated by a PYEND keyword on a separate single line.

See *PYEND – End the Definition of a PYINPUT Section* in the GRID section for a full description.

9.3.56 PYINPUT – DEFINE THE START OF A PYINPUT SECTION

The PYINPUT and PYEND keywords are a part of OPM Flow's Python scripting facility that processes standard Python commands that can be used to manipulate and define the simulators input parameters during processing of the input deck. The main purpose of the facility is to script the construction of the various keywords used by the simulator. PYINPUT declares the start of a PYINPUT Definition Section on a single separate line, which is then followed by various standard Python commands, with one command per line.

See *PYINPUT – Define the Start of a PYINPUT Section* in the GRID section for a full description.

9.3.57 REFINE – START THE DEFINITION OF A LOCAL GRID REFINEMENT

The REFINE keyword defines the start of a Cartesian or radial local grid refinement ("LGR") definition that sets the properties of the selected LGR. The keyword is then followed by the property keywords associated with the section where the keyword is being invoked. For example, if the REFINE keyword is used in the GRID section then most of the keywords in that section can be used to set the grid properties for the LGR.

See *REFINE – Start the Definition of a Local Grid Refinement* in the GRID section for a full description.

9.3.58 REGIONS - DEFINE THE START OF THE REGIONS SECTION OF KEYWORDS

Description

The REGIONS activation keyword marks the end of the PROPS section and the start of the REGIONS section that defines how various fluid and rock property data defined in the PROPS section are allocated to the individual cells in the model.

There is no data required for this keyword.

Example

```
-- ================================================================================
--
-- REGIONS SECTION
--
-- ================================================================================
REGIONS
```

The above example marks the end of the PROPS section and the start of the REGIONS section in the OPM Flow data input file.

9.3.59 RESIDNUM – DEFINE VERTICAL EQUILIBRIUM RESIDUAL FLOW REGION NUMBERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The RESIDNUM keyword defines the Vertical Equilibrium ("VE") residual flow calculation saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of relative permeability tables (SGFN, SWFN, SOF2, SOF3, SOF32D, SGOF, SLGOF and SWOF) are used to calculate the relative permeability and capillary pressure in a grid block. The keyword should only be used if the Vertical Equilibrium option has been invoked via the VE keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	RESIDNUM	RESIDNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of RESIDNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a RESIDNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.18: RESIDNUM Keyword Description

Note that any capillary pressure data on the relative permeability tables (SGFN, SWFN, SOF2, SOF3, SOF32D, SGOF, SLGOF and SWOF) will be ignored by the VE option.

Example

The example below sets three RESIDNUM regions for the model, by first setting all values to one, then setting layers 2 to 10 to two, and finally setting layers 30 to 50 to three.

```
--
--        ARRAY        CONSTANT      ---------- BOX ---------
--                                    I1  I2    J1  J2    K1  K2
EQUALS
          SATNUM       1             1*  1*    1*  1*    1*  1* / SET REGION 1
          SATNUM       2             1   2     1   2     2   10 / SET REGION 2
          SATNUM       3             1   2     1   2     30  50 / SET REGION 3
/
```

9.3.60 ROCKNUM – DEFINE ROCK COMPACTION TABLE REGION NUMBERS

Description

The ROCKNUM keyword defines the rock compaction table region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of rock compaction tables defined by the ROCKTAB keyword are used to calculate the rock compaction in a grid block.

No.	Name	Description	Default
1	ROCKNUM	ROCKNUM defines an array of positive integers assigning a grid cell to a particular rock compaction table region. The maximum number of ROCKNUM regions is set by the NTROCC variable on the ROCKCOMP keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a ROCKNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.19: ROCKNUM Keyword Description

Examples

The example below sets three ROCKNUM regions for a 4 x 5 x 2 model.

```
--
--        DEFINE ROCKNUM REGION FOR ALL CELLS
--
ROCKNUM
          2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
          3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--        ARRAY       CONSTANT     ---------- BOX ---------
--                                 I1  I2   J1  J2   K1  K2
EQUALS
          ROCKNUM     1            1*  1*   1*  1*   1*  1* / SET REGION 1
          ROCKNUM     2            1   2    1   2    1   1  / SET REGION 2
          ROCKNUM     3            1   2    1   2    2   2  / SET REGION 3
/
```

9.3.61 RPTREGS – DEFINE REGIONS SECTION REPORTING

Description

This keyword defines the data in the REGIONS section that is to be printed to the output print file in human readable format. The keyword has two distinct forms, the first of which consists of the keyword followed by a series of integers on the next line indicating the data to be printed (see the first example). This is the original formal in the commercial simulator and was subsequently superseded by the second format. The second format consists of the keyword followed by a series of character strings that indicate the data to be printed. In most cases the character string is the keyword used to load the data in the OPM Flow input deck, for example FIPNUM for the fluid in-place array. Its is anticipated that OPM Flow will eventually support the functionality of the second format only, the first format although recognized will be completely ignored.

No.	Name	Description	Default
1	EQLNUM	Print the equilibration region array.	N/A
2	FIPNUM	Print the fluid in-place array.	N/A
3	PVTNUM	Print the PVT table assignment array.	N/A
4	SATNUM	Print the saturation function (relative permeability) assignment array.	N/A
….		….	N/A

Notes:

1) The keyword is terminated by a "/".

Table 9.20: RPTREGS Keyword Description

This keyword is not supported by OPM Flow but has no effect on the results so it will be ignored.

Note

This keyword has the potential to produce very large print files that some text editors may have difficulty loading, coupled with the fact that reviewing the data in this format is very cumbersome.

A more efficient solution is to load the *.INIT file into OPM ResInsight to view the data graphically, this also has the benefit of being able to filter the grid based on I, J, K ranges and grid properties.

Examples

The first example shows the original format of this keyword; although the keyword and format are recognized by OPM Flow, the format is ignored and is unlikely to be implemented in in the simulator.

```
--
--       DEFINE REGIONS SECTION REPORT OPTION (ORIGINAL FORMAT)
-
RPTREGS
         1       2*0      1       3*1                                  /
```

The next example shows the second format of the keyword which may be supported in a future release of OPM Flow.

```
--        DEFINE REGIONS SECTION REPORT OPTIONS
--
RPTREGS
          FIPMUM    EQLNUM    PVTNUM    SATNUM                                  /
```

9.3.62 SATNUM – DEFINE THE SATURATION TABLE REGION NUMBERS

Description

The SATNUM keyword defines the saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of relative permeability tables (SGFN, SWFN, SOF2, SOF3, SOF32D, SGOF, SLGOF and SWOF) are used to calculate the relative permeability and capillary pressure in a grid block.

No.	Name	Description	Default
1	SATNUM	SATNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of SATNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1
Notes: 1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement. 2) If a cell is not assigned a SATNUM region then the default value will be used. 3) The keyword is terminated by a "/".			

Table 9.21: SATNUM Keyword Description

Examples

The example below sets three SATNUM regions for a 4 x 5 x 2 model.

```
--
--        DEFINE SATNUM REGIONS FOR ALL CELLS
--
SATNUM
          2  2  1  1  2  2  1  1  1  1  1  1  1  1  1  1  1  1  1  1
          3  3  1  1  3  3  1  1  1  1  1  1  1  1  1  1  1  1  1  1
/
```

Alternatively the EQUALS keyword could be employed to accomplish the same task, that is:

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          SATNUM      1             1*  1*   1*  1*   1*  1* / SET REGION 1
          SATNUM      2             1   2    1   2    1   1  / SET REGION 2
          SATNUM      3             1   2    1   2    2   2  / SET REGION 3
/
```

9.3.63 SKIP – ACTIVATE SKIPPING OF ALL KEYWORDS AND INPUT DATA

The SKIP keyword turns on skipping of keywords until the ENDSKIP activation keyword is encountered. All keywords and between the SKIP and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP – Activate Skipping of All Keywords and Input Data* in the GLOBAL section for a full description.

9.3.64 SKIP100 – ACTIVATE SKIPPING OF BLACK-OIL KEYWORDS AND INPUT DATA

This keyword turns on skipping of black-oil keywords until the ENDSKIP activation keyword is encountered. All black-oil keywords between the SKIP100 and ENDSKIP keywords are ignored by OPM Flow.

See *SKIP100 – Activate Skipping of Black-Oil Keywords and Input Data* in the GLOBAL section for a full description.

9.3.65 SKIP300 – ACTIVATE SKIPPING OF "COMPOSITIONAL" KEYWORDS AND INPUT DATA

Turns on skipping of "compositional" keywords until the ENDSKIP activation keyword is encountered. All "compositional" keywords between the SKIP300 and ENDSKIP keywords are ignored by OPM Flow.

See *Error: Reference source not found* in the GLOBAL section for a full description.

9.3.66 SURFNUM – DEFINE THE SURFACTANT MISCIBLE SATURATION TABLE REGION NUMBERS

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SURFNUM keyword defines the saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the model. The region number specifies which set of oil-water relative permeability tables (SWFN, SOF2, SOF3, and SWOF) are used to calculate the relative permeability and capillary pressure in a grid block. In this case the SURFNUM allocated tables assume that oil and water are miscible, whereas the SATNUM allocated tables are used to allocate the immiscible saturation tables. To use this keyword the Surfactant option must have been activated by the SURFACT keyword in the RUNSPEC section.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	SURFNUM	SURFNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of SURFNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a SURFNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.22: SURFNUM Keyword Description

Example

The example below sets three SURFNUM for the model.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          SURFNUM     1             1*  1*   1*  1*   1*  1* / SET REGION 1
          SURFNUM     2             1*  1*   1*  1*   1   1  / SET REGION 2
          SURFNUM     3             1*  1*   1*  1*   2   2  / SET REGION 3
/
```

9.3.67 SURFWNUM – DEFINE THE SATURATION TABLE REGION NUMBERS (HIGH SALINITY AND WATER WET)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The SURFWNUM keyword defines the saturation tables (relative permeability and capillary pressure tables) region numbers for each grid block, as such there must be one entry for each cell in the mode, for when the Surfactant Wettability option has been selected. The keyword may also be used with the Low Salt Brine option, in this case the water wet curves are calculated as a function of the low and high water wet salinity curves. The region number specifies which set of relative permeability tables are used to calculate the relative permeability and capillary pressure in a grid block. Note that the keyword is obligatory if the SURFACTW keyword in the RUNSPEC section has been used to invoke the Surfactant Wettability option.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	SURFWNUM	SURFWNUM defines an array of positive integers assigning a grid cell to a particular saturation table region. The maximum number of SURFWNUM regions is set by the NTSFUN variable on the TABDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a SATNUM region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.23: SURFWNUM Keyword Description

Example

The example below sets three SURFWNUM regions for the model.

```
--
--        ARRAY       CONSTANT      ---------- BOX ---------
--                                  I1  I2   J1  J2   K1  K2
EQUALS
          SURFWNUM    1             1*  1*   1*  1*   1*  1* / SET REGION 1
          SURFWNUM    2             1   2    1   2    1   1  / SET REGION 2
          SURFWNUM    3             1   2    1   2    2   2  / SET REGION 3
/
```

9.3.68 TNUM – DEFINE PASSIVE TRACER CONCENTRATION REGIONS

Description

The TNUM keyword defines the regions associated with the series of tracers associated with a phase (oil, water, or gas) in the model. The maximum number of tracers for each phase are declared on the TRACER keyword in the RUNSPEC section. Unlike other keywords, the TNUM keyword must be concatenated with the phase and the name of the tracer declared by TRACER keyword in the PROPS section. Table 9.24 outlines the format of the TNUM keyword name.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	TNUM	A four letter character equal to TNUM that is the root keyword name for this data set array.	None
2	PHASE	A one letter character string that must be equal to F or S, that is concatenated to TNUM. The letter F states that the tracer is for the "free" phase, for example oil or water, as well as gas cap gas (free gas). The letter S signifies that the tracer is a "solution" phase tracer, for example gas dissolved in oil (as activated by the DISGAS keyword in the RUNSPEC section), or condensate (vaporized oil) in the gas (as per the VAPOIL keyword in the RUNSPEC section). Note tracers that are defined by the letter S to be in the "solution" phase, must also be initialized by the "free" phase as well.	None
3	NAME	A three letter character string defining the tracer's name, which is concatenate to TNUM and PHASE to given the full name of the keyword Note it is best to void names beginning with the letters F, S, and T as these names may great naming issues in post-processing software.	None

Table 9.24: TNUM Keyword Name Format

Following the declaration of the full keyword name, TNUMPHASENAME, the keyword is followed by the data as outlined below.

No.	Name	Description	Default
1	TNUMREG	TUNREG defines an array of positive integers assigning a grid cell to a particular tracer table region. The maximum number of TNUMREG regions is set by the NTTRVD variable on the EQLDIMS keyword in the RUNSPEC section.	1

Notes:

1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement.
2) If a cell is not assigned a TNUMREG region then the default value will be used.
3) The keyword is terminated by a "/".

Table 9.25: TNUM Keyword Data Description

See also the TRACER keyword in the PROPS section and the TBLK keyword in the SOLUTION section.

Example

First define four passive tracers one for a free gas, one for dissolved gas, one for oil and one to track the water.

```
--
--        DEFINE TRACER NAMES
--
--        TRACER   TRACER
--        NAME     PHASE
--        ------   ------
TRACER
         'GCG'     'GAS'                                  / GAS CAP GAS
         'DGS'     'GAS'                                  / DISOLVED GAS
         'OIL'     'OIL'                                  / OIL
         'WAT'     'WAT'                                  / WAT
/
```

Given a 100 x 100 x 5 grid with DISGAS activated in the RUNSPEC section, then the following TNUM keywords define the various tracer regions given that NTTRVD equals four on the EQLDIMS keyword in the RUNSPEC section.

```
--
--        DEFINE PASSIVE TRACER CONCENTRATION REGIONS
--
TNUMFGCG
          1000*1
          1000*2
          1000*2
          1000*2
          1000*2
/
TNUMSDGS
          1000*1
          1000*1
          1000*1
          1000*1
          1000*1
/
TNUMFOIL
          1000*3
          1000*3
          1000*3
          1000*3
          1000*3
/
TNUMFWAT
          1000*4
          1000*4
          1000*4
          1000*4
          1000*4
/
```

The keyword name is derived from the TNUM keyword, plus either F or S, plus the tracer name declared in the TRACER keyword. For example for the gas cap (free gas) this would be TNUM+F+GAS to give the TNUMFGAS keyword. And for the dissolved (solution) gas this would be TNUM+S+DGS resulting in the TNUMSDGS keyword.

9.3.69 TRKPF – DEFINE PARTITIONED TRACER REGIONS

Description

The TRKPF keyword defines the regions associated with the series of partition tracers and the partitioning tables allocated to grid blocks in the model, for when the Partitioned Tracer option has been enabled by the PARTTRAC keyword in the RUNSPEC section. The maximum number of tracers for each phase are declared on the TRACERS keyword in the RUNSPEC section. Unlike other keywords, the TRKPF keyword must be concatenated with the name of the tracer declared by TRACER keyword in the PROPS section. Table 9.26 outlines the format of the TRKPF keyword name.

This keyword is not supported by OPM Flow but would change the results if supported so the simulation will be stopped.

No.	Name	Description	Default
1	TRKPF	A five letter character string equal to TRKPF that is the root keyword name for this data set array.	None
2	NAME	A three letter character string defining the tracer's name, as declared by the TRACER keyword, which is concatenate to TRKPF to given the full name of the keyword Note it is best to void names beginning with the letters F, S, and T as these names may great naming issues in post-processing software.	None

Table 9.26: TRKPF Keyword Name Format

Following the declaration of the full keyword name, TRKPFNAME, the keyword is followed by the data as outlined below.

No.	Name	Description	Default
1	TRKPFREG	TRKPFREG defines an array of positive integers assigning a grid cell to a particular tracer table region. The maximum number of TRKPFREG regions is set by the NTTRVD variable on the EQLDIMS keyword in the RUNSPEC section.	1
Notes: 1) The number of entries should correspond to the NX x NY x NZ parameters on the DIMENS keyword in the RUNSPEC section, unless the BOX keyword defines a sub area of the grid, in which case the total number of entries should correspond to the number of cells defined by the BOX statement. 2) If a cell is not assigned a TRKPFREG region then the default value will be used. 3) The keyword is terminated by a "/".			

Table 9.27: TRKPF Keyword Data Description

See also the TRACER and TRACERKP keywords in the PROPS section and the TBLK keyword in the SOLUTION section.

Example

First define one mult-partitioned tracer for the water phase.

```
--
--        DEFINE TRACER NAMES
--
--        TRACER   TRACER   TRACER  PARTITION  NUM   ADSOR
--        NAME     PHASE    VOLUME  PHASE      K(P)  PHASE
--        ------   ------   ------  ---------  ----  -----
TRACER
         'WAT'     'WAT'    1*      MULT       2     ALL    / WAT
/
```

Then for a given a 100 x 100 x 5 grid assign the partitioned tracer regions and K(P) tables, based on two regions.

```
--
--        DEFINE PARTITIONED TRACER REGIONS
--
TRKPFWAT
          1000*1
          1000*1
          1000*2
          1000*2
          1000*2
/
```

The keyword name is derived from the TRKPF keyword, plus the tracer name declared in the TRACER keyword, in this case the keyword name is TRKPFWAT.

9.3.70 WARN – ACTIVATE WARNING MESSAGES

Turns on warning messages to be printed to the print file (*.PRT); note that this keyword is activated by default and can subsequently be switched off by the NOWARN activation keyword. The warning messages may be turned on and off using keywords WARN and NOWARN. OPM Flow always prints error messages.

See *WARN – Activate Warning Messages* in the GLOBAL section for a full description.

9.3.71 WH2NUM – DEFINE WAG HYSTERESIS SATURATION TABLE REGION NUMBERS (TWO PHASE)

RUNSPEC	GRID	EDIT	PROPS	REGIONS	SOLUTION	SUMMARY	SCHEDULE

Description

The WH2NUM keyword defines the two phase Water-Alternating-Gas ("WAG") hysteresis tables (relative permeability and capillary pressure tables) region numbers for each grid block, for when the hysteresis option has been activated by the WAGHYSTR variable on the SATOPTS keyword in the RUNSPEC section. The region number specifies which set of relative permeability tables (SGFN, SWFN, SOF2, SOF3, SOF32D, SGOF, SLGOF and SWOF) are used to calculate the relative permeability and capillary pressure in a grid block. Note that this keyword if the two phase water relative permeabilities WAG option.
